The wars and commotions of India have thus at length come to a close, and Great Britain remains the sole ruler of that vast empire. The native princes, rajahs, and petty feudatories of the country, hold their several dignities and stations in the great political system of which they form a part, under the guarantee of her sovereign authority. The nature of the subsidiary alliances of the British with the Indian states has been already described—namely, the furnishing a force, which is stationed in the dependent state for its protection, and the latter a territory equivalent to its maintenance, and further submitting, in its foreign relations and differences with other states, to the arbitration of the British government, though free from all control in its internal concerns. The powers with whom subsidiary alliances have been formed are the nizam or ruler of Hyderabad; the king of Oude; the Guicowar, whose dominions are in the province of Gujerat; Holkar, who has been deprived of all his dominions S. of the Nerbuddah; Scindia of Gwalior, reduced since 1844 to insignificance; the rajahs of Cutch, of Mysore, of Travancore, and of Cochin. The protected states are so far reduced to dependence that they agree to maintain no correspondence with foreign powers of a political tendency without the privilege or consent of the British government; and not to go to war, but to submit all their differences with other states to the arbitration of the British. They are independent in their internal concerns, and have not, like the others, a British force stationed within their territories. They are bound to furnish a contingent of troops when required, which in the field act in subordination to the British commanders. These states are,—1*st*, in the N.W., Cashmere and the Sikh and Hill states, on the left bank of the Sutledge. 2*d*, Rajpoot states; Bicanere, Jesselmere, Jeepoor, Joudpoor, Odeypoor, Kotah, Boondi, Serowey, Kishengurh, Dowleah and Pertaubgurh, Doongapore, Jhallawar, Banswarra. 3*d*, Jaut states on the right bank of the Jumna; Bhurtpore, Ulwar or Macherry, Kerowlee. 4*th*, Boondelah states; Sumpthur, Jhansi, Oorcha or Tehree, Dutteah, Rewah, &c. 5*th*, States in Malwah; Bopaul, Dhar, Dewas, Rutlaum, Silana, Nursinghur, Amjherra, &c. 6*th*, States in Gujerat; Pahlunpore, Rahdunpore, Rajpeepla, Loonawara, Soonth, the states in the Myhee Caunta, the Kattywar states. 7*th*, States on the Malabar coast (chiefly Mahratta); Sawunt Warree and Colapore. 8*th*, North-eastern frontier; Siccim, Coosh Behar, Cossya Hills, &c. &c. Yet even in some of these protected states, as for instance, in Colapore and Sawunt Warree, the British government has been compelled to assume the administration, and to carry on the government in the names of the native rulers, who are placed in the position of stipendiaries. With respect to Colapore the retransfer of the government to the chief is made dependent upon the opinion which may be entertained by the British government of his character, disposition, and capacity to govern. In Sawunt Warree the heir-apparent having forfeited his rights by participating in the rebellion of 1844, the country, upon the death of the present chief, will be at the disposal of the paramount authority. In some other states, as those in Kattywar, the Myhee, and Rewa Cauntas, and others which are tributary to the guicowar, arrangements have been made under which the guicowar abstains from all interference, and the British government undertakes the management of the country, guaranteeing the guicowar's tribute. In carrying out such arrangements, the British government has conferred important benefits upon the country, by abolishing infanticide, suttee, and slave-dealing. It will thus be seen that, with the exception of the king of Burmah, and the rajah of Nepaul, there now remain no independent princes in India. The rajah of Nepaul, moreover, though not otherwise dependent, is bound by treaty to abide by the decision of the British government in the event of any dispute arising between himself and his neighbour the rajah of Siccim, and he is also restrained from employing in his service any European or American subject. The rajah of Dholpore, in Central India, holds his possessions in absolute sovereignty, free from any right of interference on the part of the British government, as does also the rajah of Tipperah, a wild jungly tract lying on the eastern frontier of Bengal towards Burmah, with the ruler of which the British government has never established any diplomatic relations; but the resources of these petty potentates are too unimportant to entitle them to be regarded as forming exceptions to the general rule of dependency. Over all the other native states in India the paramount authority of the British power has been established, and the relation of ally has in all cases merged into that of superior and dependent.

[1] For a full account of the operations of this war, see the article Ava.

Causes of the British success.

The rise of the British power, from small beginnings into so vast an empire, is one of those surprising revolutions in human affairs which gives to history the air of a romance. The managers of a trading company in London are now the lords of a kingdom ten times the size of England, and containing upwards of 150 millions of inhabitants; they engage in war and make peace; they rule over kings and princes, dethroning some and setting up others in their stead; and in their counting-house in Leadenhall Street they regulate, not the chances of profit and loss, but the concerns of a vast empire. Yet the causes of this great revolution are simple and obvious. The extensive dominion acquired by the British in India is the consequence of long-continued military success; it is the fruit of victory in many a well-fought field, the triumph of European discipline and science over the rude valour of the hasty levies and imperfectly trained militia of the East. In the course of this long contest the British had frequently to contend with few against many, and their empire sometimes tottered on the verge of ruin, as in the invasion of the Carnatic by Hyder Ali. But the steadiness of the European infantry still repelled the irregular charges of the Mahratta horse, and triumphed in the end; and to this powerful instrument, namely, a well-disciplined military force, wielded by skilful hands, the British are indebted for the conquest of Hindustan. The extension of their empire in India was always discountenanced by the Directors at home, who issued their repeated and peremptory commands on the subject. Yet it might have been easily foreseen, that, the foundation once laid, the superstructure would naturally arise; that having made the first step, the British would not readily stop short in their course. The frailty of man has never been able to resist the allurements of ambition; the dazzling prize of extensive dominion has in all ages been pursued through the paths of blood; and it was scarcely to be imagined that the Company's servants in India would resist its temptations, more especially as there were many circumstances which gave a plausible colour to their ambitious views. The native powers, alarmed by the territorial acquisitions of the British, naturally combined against them as the common enemies of Indian independence. The British, on the other hand, convinced of their strength, and of the hatred and jealousy which they had excited throughout India, and easily yielding to the least surmise of hostile coalitions, often took up arms to avert distant and doubtful dangers; and victory being still the result of each new struggle, they assured their safety by the ruin of their enemies, and by the extension of their power. Thus the hostile designs of Tippoo failed to attain maturity, and he was overthrown before he could become formidable.

Internal policy of the British.

t will now be proper to give a brief account of the domestic policy of the Company as sovereigns of India, especially in those important departments in the civil administration of every country, namely, the revenue, the judicial establishments, and the police.

Land-tax under the Mogul empire.

Under the Mogul government, the public revenue was chiefly derived from a general land-tax, and the regular payment of this tax was the tenure by which property was held throughout the empire. The lands were possessed by different descriptions of owners or occupiers, under the titles chiefly of zemindars or polygars, the military chieftains of the Carnatic, talookdars, ryots, maliks, mecrassadars, nair mulguenies, bhoomias, &c.[1] When Hindustan was brought under the sway of the British, they were necessarily ignorant of the manners and usages of the people, and of the peculiar structure of a Hindu community; and hence the nature of the tenures under which land was held, and of the different descriptions of land owners and occupiers, has been a standing subject of controversy amongst the Company's servants, some insisting that under the Mogul despotism, as over all the East, the sovereign is the sole proprietor of the lands within his dominions; that no private right of property has ever been recognised in any of the great monarchies of Asia; and that all grants of land are resumable at the pleasure of the prince. According to this theory, the zemindar is considered merely as a species of steward or factor, appointed by the government, to collect and superintend the land revenues; and after reserving a suitable portion for his own maintenance, to remit the surplus to the imperial treasury. The rights of the talookdars, an inferior description of holders, and the ryots, and other occupiers of land, were still more imperfectly understood by the English when they acquired the dominion of Bengal; but, under the idea of the sovereign's indefeasible right in the soil, they naturally considered them as tenants at will, to be dealt with like other tenants in the same situation, at the pleasure of the proprietor. This hypothesis of the sovereign's proprietary right was eagerly adopted by the English, and has been boldly followed up in practice. It has, as might have been expected, led to extensive confiscations of land, to great changes in the state of property, and to much distress and confusion, as will be afterwards narrated; and it will be proper, therefore, briefly to inquire how far this claim accords with any legal right, and still more with any principle of enlightened policy.

Sovereign's proprietary right considered.

In a government purely arbitrary, where every man holds life and liberty at the mercy of the sovereign, it is extremely difficult to distinguish between the exercise of legal rights and the outrages of abused power. That the despotic rulers of the East might take possession of the land, or of any other description of property belonging to their subjects, and that this was their practice, can hardly be questioned. But might does not constitute right; nor by such acts of tyranny can they become lords of the soil in any legal sense, any more than of the lives and liberties of their subjects, because they often massacre and torture them at their pleasure. The law of conquest, which is the law of the strongest, gave to the Mahommedans possession of India, which they desolated with fire and sword, and took possession of the lands and properties of the inhabitants, who, according to their approved practice, might have been all put to the sword, as the redemption price of their blood. This was the only title which the Mogul emperor could have had to the lands within his dominions, namely, that he had seized upon them by force; and in countries long subject to Mahommedan rule, or to the Mahrattas and other domestic tyrants, all the ancient rights of the proprietors have accordingly been obliterated. But these acts of tyranny and spoliation can never be construed into legal precedents, nor can they ever confer any title; and it seems a gross abuse of words to call that a right which is merely a deed of violence.

The monarch or the emperor was no doubt styled, in the true strain of oriental flattery, the sole proprietor of the soil, and the lord of the universe; and this he may have been originally, in the same manner as the monarchs of Europe were under the feudal system. According to the feudal law, they were the supreme lords of all the conquered territories, which they granted as fiefs to their vassals, on condition of military service; and from the monarch a subordinate chain of vassalage extended downward to the lowest tenant. These lands were at first granted for a year, but afterwards for life; at length they became hereditary, and descended to the son, or to more distant relations; and thus they finally became a permanent property. But the form of the original tenure is still maintained. They still hold of the sovereign, to whom, at the death of each heir, a formal surrender is made of the property, and a new charter is granted as a matter of course. But this right of the crown, by which in former times the property was actually resumed at the death of the proprietor, has now become a mere legal fiction, an evidence only of the original tenure by which the property was held; and we may easily imagine the disorder and injustice that would be introduced into any European country by a conqueror, who, guided by feudal forms, in opposition to immemorial usage and fixed law, was to resume all property holding of the crown, or of any other superior. In like manner, in Hindustan, though the sovereign was styled the proprietor of all the lands within his dominions, and in legal theory might be so, it would be rash to infer from this the actual extinction of all proprietary rights. Under the Mogul government a heavy tax was, no doubt, laid on the land, which was the main source of the public revenue. But individual rights of property might nevertheless exist; and their non-existence has certainly never been satisfactorily proved; so far from it, that the advocates of the sovereign proprietary right seem to have nothing to oppose to immemorial usage, and to the principles of justice, but legal forms and the acts of despotic power.[2]

But the abstract question of right here merges into the higher question of policy. It would be the interest of a sovereign, even if he were proprietor of the soil, to commute his rights for a moderate assessment, which in the end would ensure the general prosperity of the community. A land-tax which leaves a bare maintenance to the cultivator discourages agriculture, population, and the growth of capital; it is indeed an interdict on all improvement. Its produce cannot be increased except by the most ruinous extortions, though it will necessarily decrease with the desolation of the land, which it tends to promote. No country can be improved and cultivated where the rights of property are loaded by a public tax. Would the wastes of America, we may ask, be so quickly converted into fruitful fields, if the government were to come in for the largest share of the produce, if the owner were placed under the strict surveillance of the excise, and obliged to account for every particle of his crop. In Europe the church tithes have been justly complained of as a great obstruction to improvement. But a tax such as we have described, which, however it varied in its amount from a fourth, a third, or half the gross produce of the soil, generally left only a bare maintenance to the cultivators, is far more pernicious in its operation; and it is indeed owing to its pressure that so large a portion of Hindustan still remains a primitive wilderness. Mr L. Place, to whom was committed, in 1790, the settlement of the Jaghire, a tract of country in the Carnatic that had been ruined by the invasion of Hyder Ali, after mentioning the desolation of the country, and that the inhabitants would not cultivate any fields except under a secure tenure, adds, that "by granting them lands to them and their heirs for ever, so long as they continued in obedience to the circar (government), and paid all just dues, he was enabled to convert the most stubborn soil and thickest jungle into fertile villages."

---

[1] See Colonel Todd *On the Feudal System in Rajast'han*, vol. i. chap. i. p. 167. See also *Fifth Report*, p. 822–23, Extracts from Mr Thackeray's Report, dated 4th August 1807.

[2] The masterly reports of the Company's collectors in Southern India all concur in stating the hereditary rights of individuals in the land to be clear and unquestioned from the most remote ages. "In tracing their (the Hindus') past situation," says one of the collectors, "it is not to be discovered, that during the revolutions of many ages, from the reign of their first princes, until the final downfall of the Hindu authority, any questions ever existed, in any stage of the Hindu history, as to the right of the people to the lands of the country, excepting villages or lands totally waste, and that had escheated to government. On the contrary, they appear to have been transmitted to them, from the most remote era, down to the present time, without interruption; these rights are supported by usages, which could never have prevailed, but for their universal acknowledgment; and, in the repositories of their history and their laws, we find the right of the people to property in lands repeatedly acknowledged and preserved." (Extract from Report of Collector of Southern Polygar Peshcush, 29th December 1800, *Fifth Report*, Appendix, p. 828.)

Land titles among the Hindus.

It was extremely natural for those who had succeeded to the rights of the sovereign to exaggerate the extent of those rights, and to believe in the convenient doctrine of his proprietary title to the land. But although many ancient rights were unquestionably trampled down and for ever lost in the violence of the Mahommedan conquest, yet recent investigations have discovered, amidst the ruins of Hindu institutions, many relics of ancient manners, and the clearest titles of individual proprietors to the possession of the soil. In carrying into effect the permanent settlement by Lord Cornwallis of the land revenues in Bengal, the collectors were embarrassed by the claims of the petty talookdars, who insisted on a hereditary right of property in the soil; and the maliks, who with vehemence urged the same claims, and affirmed that the zemindars and talookdars had no deeds to show that could deprive them of their just rights. They claimed the land as their paternal inheritance, and refused to settle for the public revenue on any other terms than as proprietors. The collector was deeply impressed with the justice of their claims; and Mr Rickards, in his masterly work on Indian finance, affirms that the maliks were really proprietors, stripped of their rights by the usurpations and exactions of the zemindars and their aumils or collectors.[1] In the district of Dacca, the private rights of property were found to exist in their full force; even the unproductive jungle and waste around the town was claimed by individuals, "who," says the collector, "though they receive no profit from it, and are too indolent themselves to make it productive of any, will not suffer others to bring it into a state of cultivation without some recompense; and so very tenacious are they of it, that even in the suburbs of the city, which for three or four miles is almost an impenetrable jungle, infested by wild ferocious animals, a man cutting down a single tree will be sued by the proprietor for damages."[2] A clearer idea cannot possibly be conveyed of the rights of property, and of the solid foundation on which they rest in Bengal, as in all other countries. The accurate researches of Colonel Todd, who drew his information not merely from written records and deeds, but from the more durable tablets of stone found amidst the ruins of the fallen pile, have laid open the ancient tenures and institutions of Northern India; and in his lively delineation of those ancient manners we recognise all the peculiar features of the feudal system. There were in Rajast'han or Rajpootana two classes of landholders, the one the Grasya-t'ha-cour or lord, the other the bhoomia;[3] the first holding land by a grant from the prince on the condition of military service, "renewable," says Colonel Todd, "at every lapse, when all the ceremonies of resumption, the fine of relief, and the investiture, take place;"[4] the other an allodial proprietor, who holds prescriptive possession, who succeeds to his inheritance without any fine, though he pays a small annual quit-rent, and may be called upon for military service in the district where he resides, which is chiefly composed of the rocks and wilds that afford a refuge from oppression, and where the bhoomias, being numerous, form a species of local militia.

Landed property in the South of India.

In the southern countries of India, in Tanjore, Tinnevelly, Canara, Malabar, &c. where the Mahommedan rule had only been temporary or partial, the rights of property were not extinguished; they were indeed encroached upon, and were, as Mr Rickards observes, "in progress of actual extinction, and approached nearer and nearer to this term in proportion to the duration of Mussulman tyranny." The tyranny and exactions of Hyder Ali and his son Tippoo had nearly extinguished all proprietary rights in Mysore and in Malabar; and most of the Hindu landholders were compelled to seek refuge in Travancore. "I was," says Mr Rickards, "personally acquainted with some who, from the same causes, deserted their estates, and retired for safety into Coimbetoor."[5] But those rights were not obliterated, and the investigations of the British functionaries, skilled in the native languages and manners, brought to light in these countries the ancient condition of property, and the clearest titles of individual proprietors.[6] The notion of the sovereign's proprietary right to the whole produce of the land was interwoven with the Mogul system of finance, and the East India Company had always acted on the same maxims. Accordingly, Mr Place and others, when they entered on the management of the Jaghire, Canara, Malabar, &c. were prepossessed with the same ideas, and gave the most liberal interpretation to the Company's proprietary rights, considering the occupants and cultivators of the land as mere tenants at will. But they were soon undeceived by glaring facts. They found that the possessors of the land had the right of selling, bestowing, devising, or bequeathing their lands, in whatever manner they might deem expedient; that the lands, whether they belonged to villages, and were cultivated in shares by their common labour, or to individuals, were their absolute property, of which they could only be deprived by an act of violence. This proprietary right was termed *meerass*, a Persian or Arabic term for land;[1] and the proprietor a *meerassadar*. "Whatever may have been the origin of these rights," says the Fifth Report (p. 105), "they are regarded by the people as hereditary rights," and were, according to the Hindus, far more ancient than the Moorish conquest. Estates were found to consist of from 4000 to one acre of land; and where they were large, or were divided amongst a numerous proprietary, they were tilled by *parakudis* or *pyacaris*, who were paid for their labour, and who possessed hereditary rights of occupancy as cultivators. Common labourers were also occasionally hired; and slaves are numerous all over the country, attached to the soil, and in a state of villenage, as were formerly the cultivators in Europe. In Canara, the same rights of property exist in the land; and the proprietors are known under the appellation of *nair mul guenies*, who, like the meerassadars, have tenants in perpetuity, or *shud mul guenies;* and tenants at will, or *chalie guenies*. Of these tillers it is observed in the Fifth Report of the Select Committee on the affairs of the East India Company, that "the lands in general appear to have constituted a clear private property, more ancient, and probably more perfect, than that of England. The tenure, as well as the transfer, of this property, by descent, sale, gift, and mortgage, is fortified by a series of regular deeds, equally varied and curious, and which bear a very strong resemblance in both parts of the country. The proprietary right is either vested in individuals, or in copartnerships of persons, each of whom possesses an unalienable interest in the estate, proportioned to the share of the property of which he has become possessed."

---

[1] See *Fifth Report*, p. 493, Copy of a Letter from the Collector of Shahabad to the Board of Revenue, dated 29th September 1789. Rickards, vol. i. chap. i. sect. iv. p. 368. *Mal*, says Rickards, is an Arabic word, denoting wealth, property, revenue, rent, particularly that arising from land; and *Malik* means master, lord, proprietor, owner of such rent.

[2] *Fifth Report*, Appendix, p. 495, Letter from the Chief of Dacca to the Board of Revenue, dated 23d July 1786. It was proposed that the government should clear away this jungle, and cultivate the land. But this "laudable plan," says Mr Day, chief of Dacca, cannot therefore be carried into effect, "without creating great dissatisfaction," as every seizure of private property necessarily does; yet he observes, that the "prejudice (*i. e.* the robbery) of a few individuals, should be no impediment to the adoption of a plan which has for its object the benefit of the community at large."

[3] The term *bhoomia* is, according to Colonel Todd, a most expressive and comprehensive name, importing absolute identity with the soil; *bhoom* meaning land. (Todd, vol. i. p. 168.)

[4] *Annals and Antiquities of Rajast'han*, by Lieutenant-Colonel James Todd, vol. i. p. 164.

[5] Vol. i. p. 283.

[6] See *Fifth Report of Select Committee*, p. 714, Report of Mr Place respecting the land tenures in the Jaghire; Report of Mr Hodgson on the revenues of Tinnevelly, *Fifth Report*, p. 832; Report on Revenues of Dindigul, p. 978. Mr Place at first agreed to the favourite theory that the sovereign was lord of the soil, and that the occupants of land in India were mere tenants at will. But on further inquiry, he was convinced that the *meerussadars* were hereditary proprietors. Report of Collector of Tanjore and Trichinopoly, 8th September 1805: "Immemorial usage," he observes, "has established, both in Tanjore and Trichinopoly, that the occupants, whether distinguished by the names of *meerassadars* or *mahajanums*, have the right of selling, bestowing, devising, or bequeathing their lands in the manner which to them is most agreeable." "It is fortunate that, at the moment when we are consulting on the means of establishing the property and welfare of the numerous people of these provinces, we find the lands of the country in the hands of men who feel and understand the full rights and advantages of possession; who have enjoyed them, in a degree more or less secure, before the British name was known in India; and who, in consequence of them, have rendered populous and fertile the extensive provinces of Tanjore and Trichinopoly. The class of proprietors to whom I allude are not to be considered as the actual cultivators of the soil; the far greater mass of them till their lands by means of hired labourers, or by a class of people termed *pullers*, who are of the lowest, and who may be considered as the slaves of the soil. The landed property of these provinces is divided and subdivided in every possible degree. There are proprietors of 4000 acres, of 400 acres, of forty acres, and of one acre."

There is another class of landholders in Malabar, denominated *jelmkars*, or *jenmkars*, who possess allodial rights, acknowledging no superior, and who were exempt from the government-tax.[2] When Hyder conquered the country, his first act was to declare half the produce of the soil to belong to the sovereign; and it was in this manner that in Hindustan all private rights were trampled upon and gradually obliterated. But these exactions of tyranny are not to be confounded with the legal claims of the state. Mr Hodgson, in his report on the revenues of Coimbetoor, justly observes, that whatever abuses took place under the Hindu or Mahommedan princes, "what was fair assessment, and what was exaction, was well known to the party governing and those governed."[3] From all this concurring evidence, it is clear that the sovereign's proprietary right in the soil was in Hindustan, as in Europe, more nominal than real; that prior to the Mahommedan conquest the land was divided amongst individual proprietors, and that the bhoomia of Rajpootana, the malik of Bengal, the meerassadar of Southern India, the nair mul guenies of Canara, and the jelmkars of Malabar, were all hereditary landholders, with legal rights, of which they could only be dispossessed by the violence of despotic power.

Zemindars.

The Mahommedan conquest subverted most of the ancient rights and titles of the Hindu landholders, and introduced into Bengal the title of zemindar or landholder, from the Persian word *zemin*, land; respecting whose rights and duties so wide a difference of opinion has prevailed. Without entering further into this controversy, which, as respects the zemindar, is more a speculative than a practical question, it may be observed, that the zemindars had lived for centuries in great splendour on the produce of their lands, which had quietly descended under the existing tenure through successive generations; that they had the power to sell, to alienate, or to mortgage; and that as long as they paid the annual tribute to government, they enjoyed secure possession of their lands. Under a despotic government arbitrary ejectments might no doubt occur; but these were rare, and they were universally regarded, both in law and in usage, as the illegal outrages of abused power. It is admitted on all hands that these rights belonged to the zemindars; and the only point that still remains in dispute, and it does not appear very material, seems to be, whether, according to the theory of the Mogul constitution, the receipt of the land-tax by the sovereign, or of his allotted share of the produce by the zemindar, entitled the one or the other to the character of proprietor of the land.

The zemindars, being bound to the state for the revenue, were necessarily invested with the power of collecting the land-tax from the subordinate landholders and tenants. They united, in this manner, legal authority with the possession of property, whilst, as judges and magistrates, they administered both civil and criminal justice, and were held responsible for all crimes committed within their respective boundaries. These powers they frequently abused, and oppressed the inferior landholders, the talookdars and the ryots, the hereditary cultivators, or, as others consider them, the proprietors of the land, by the most cruel exactions. It was to the principal landholders that government looked for the discharge of its demands, whilst the inferior occupants and tenants were bound each to his immediate superior for their several proportions of the stipulated tax.

Other tenures.

There were various other tenures by which lands were held in Bengal, namely, the Jaghire, Altumgha, Muddud Mash Ayma, and others. The first were grants of land on the condition of military service, or for the support of garrisons or any other public establishment, especially of a military nature. This would appear also to have been the conditions of the zemindary tenure, as Mr Rickards states that the zemindars of Bengal are expressly mentioned in the

---

[1] This term of *meerass* was introduced by the Mohammedans. "Swastrium," says Mr Hodgson, "is the Sanscrit word, and is generally used by the Brahmins; and *caneatchy* by those Shudras (cultivating castes) who may not have adopted the general term *meerass*." (See *Fifth Report*, Appendix, p. 832, Extract from Hodgson's Report on the Revenues of Tinnevelly, 24th September 1807.) Caniatchikedar is possessor or proprietor, and fully answers to jelmkar. (See p. 833, *Fifth Report*, Mr Hodgson on the Revenues of Dindigul, 28th March 1808.)

[2] *Jelmkar* or *jenmkar* means an allodial proprietor; the term *jenm* meaning properly allodial right.

[3] *Fifth Report*, p. 834. "Neither the Hindu nor Mussulman government appear (supposing their right in the soil as proprietors to be indisputable, and proprietary right to be a right to demand what the proprietor pleases for his land) ever to have exercised the right. What was fair assessment, and what was exaction, was well known to the party governing and those governed. It is true, where, as under Tippoo Sultaun's reign, exaction had no limit, landed property could have no value; but where fraud could not counteract oppression, a hope of change for the better, or inability to resist, produced submission, till the load became too heavy to bear, and emigration the only source of relief."

Ayeen Akberry as furnishing their several contingents of cavalry, infantry, and artillery. The Altumgha grant, according to the terms of it, was in perpetuity. The other grants were for the support of learned men, or religious establishments. Many of the public functionaries of the Company denied the validity of these grants; they estimated the average loss, as it was called, as if there could be any loss where there never was any right, on these grants in Bengal and the ceded provinces at two and a half millions sterling, and contended that they were resumable, and were often actually resumed, at the pleasure of the prince. Colonel Todd, however, mentions, that in Rajpootana this right of resumption had fallen into disuse. "The right to resume," he observes, "may be presumed to exist; while the non-practice of it, the formalities of renewal being gone through, may be said to render the right a dead letter;" and, quoting a passage relative to the fiefs in Europe, that they were first moveable or resumable at pleasure, then perpetual or for life, and finally hereditary, he adds, "this is the precise gradation of fiefs in Mewar, a division of Rajpootana. There is reason to believe that these grants were in a progress to permanency all over India." But all permanent property in land was discountenanced by the policy of the British in India, who were perpetually picking holes in the tenures by which it was held, even where the deed of grant expresses in the plainest terms that it is perpetual, "from generation to generation."[1]

Division of the country into villages.

The country of Hindustan is divided into villages or districts, each comprising some hundreds or thousands of acres of arable and waste land. Every village is a separate community or township, and has its own establishment of public officers and tradesmen. These consisted of the *potail*, or head inhabitant, whose business it was to superintend the affairs of the village, to settle disputes amongst the inhabitants, to attend to the police, and to the collection of the public tax; the *curnum*, to whom it belonged to keep an account of the cultivation and produce of the land, to register the proprietors of the village, and to attest all deeds of sale, transfer, or assignment; the *boundary-man*, who preserves the limits of the village, or gives evidence of them in case of dispute; the priest, the schoolmaster, the astrologer; the smith, the carpenter, the potter, the washerman, the barber, the cowkeeper, the doctor, the dancing-girl, the musician, the poet, who were each rewarded for their labours out of the produce of the village lands. The amount of their shares on the gross produce is estimated at five and a half per cent. The collectors were allowed ten per cent., and after these and other minor deductions had been made, the remaining proportion of the crop was divided between the sovereign and the cultivator, in equal proportions. "Under this simple form of municipal government," says the Fifth Report, "the inhabitants of the country have lived from time immemorial. The boundaries of the villages have been but seldom altered; and though the villages themselves have been sometimes injured, and even desolated, by war, famine, and disease, the same name, the same limits, the same interests, and even the same families, have continued for ages. The inhabitants give themselves no trouble about the breaking up and division of kingdoms; while the village remains entire, they care not to what power it is transferred, or to what sovereign it devolves; its internal economy remains unchanged; the potail is still the head inhabitant, and still acts as the petty judge and magistrate, and collector or renter of the village." So deeply attached are the Hindus to their native villages and local manners, that, however they may be scattered by the desolation of war, their affections still centre in one common and cherished spot; insomuch that, in 1817, as is mentioned by Sir John Malcolm, and as has already been noticed, when peace was re-established in Central India, by the expulsion of the Pindarees and other freebooters, who laid waste the country, the inhabitants and officers of the villages re-assembled from every quarter, and the resurrection of these communities into life and action seemed to have been the work of an instant.

Land-tax.

The land-tax of the village is collected by the potail, assisted by a train of petty officers or under collectors, the putwarries, the peons, the pykes, and others, whose salaries form a deduction from the gross rent. The potail pays his collections to the zemindar, from whom they were received, under the Mogul government, by a higher officer, and finally remitted to the imperial treasury. The accounts of the *curnum*, or the *canongoe*, were also transmitted through various gradations of accountants, who superintended and checked the collection and receipt of the public revenue. In the year 1573, during the reign of Akbar, when the Mahommedans had completed the conquest of Hindustan, Rajah Torrel Mull, minister of finance to the emperor, from the accounts furnished by the canongoes and collectors of the revenue paid by the ryots, formed a general rent-roll for all the country, as well as a scheme of division, fixing the separate proportions of districts and villages. The revenue thus settled for Bengal, Behar, and Orissa, and usually called *tumar jumma* (rent), or standard assessment, amounted to

[1] Colonel Munro, a great authority on all Indian questions, in a paper of remarks on a decision of the chief justice of Madras respecting a jaghire estate that was resumed by the Company, argues, from the arbitrary practices of Indian princes in taking away these rights, that no such rights exist, although they are defined in the clearest terms. "The grant," he observes, "is in the usual form,—'to be enjoyed by him and his descendants *for ever, from generation to generation.*' He is authorized to divide it among his descendants; and the local officers are required to consider the perwannah 'as a most positive peremptory mandate, and not to require a fresh sunnud every year.' The terms employed in such documents, 'for ever,' 'from generation to generation,' or, in Hindu grants, 'while the sun and moon endure,' are mere forms of expression, and are never supposed, either by the donor or the receiver, to convey the durability which they imply, or any beyond the will of the sovereign. The injunction with which they usually conclude—'Let them not require a fresh sunnud every year,' indicates plainly enough the opinion that such grants were not secure from revocation." (In Consultation, 15th March 1832.) The language here may be a "mere form of expression," yet it is impossible to frame in words a clearer legal title; and the doubt is, whether the subversion of such a title, however common amongst the despotic princes of Hindustan, ought not to be regarded as a tyrannical act rather than a legal precedent. No landed proprietor would, with such a title, surrender his estate, except to the power of the strongest. Custom may have rendered such acts familiar to the prostrate people of Hindustan; but if words like these are to be held as mere official forms, it is clear that no legal title to property can exist in India. Sir Thomas Munro mentions several examples of land held under common jaghire grants descending through several generations. He still insists, however, that, by the invariable custom of the country, they are resumable at the pleasure of the prince, though it seems extremely doubtful how far the practice of a despotic government in resuming lands can be received as a precedent against such a clear legal title.

The arbitrary taxes termed Abwabs, added to the original standard assessment, consisted of duties on the transit of goods through the different chokies or toll-bars of the country, of taxes on cattle and stock of every description; of a capitation tax; of a tax on shops, manufactures, or stock in trade; and of fines and other arbitrary exactions; and, in proportion to the demands made on the zemindar, he was empowered to augment the contribution of his tenants. The standard revenue of Torrel Mull, amounting to L.1,202,979, appears to have been all that the country could bear; for, inconsiderable as was the augmented revenue of Jaffier Khan, it was only obtained by the most cruel tortures inflicted on the zemindars, many of whom he confined in pits filled with ordure, which he termed in derision Bykaut, or Hindu Paradise. In the reign of Meer Cossim, who was set up by the English, to whom he promised large sums as the price of his elevation, these oppressions were carried to a still greater height. The policy was to ascertain, by exact money, the produce of the land; and the whole surplus, after allowing a bare maintenance to the cultivator, was swept into the treasury.

English invested with the sovereignty of Bengal.

Although the ascendency of the English had for some years been thoroughly established in Bengal, and although they were formally invested in 1765 with the sovereignty of the country, its affairs were still administered in the name of the native prince, and according to the forms and policy of the ancient constitution. Justice was still dispensed by the native courts, and by the nabob's officers; the revenues still flowed through the same channels into the public exchequer; and all transactions with foreign powers were carried on under the same authority as formerly. But such was the increasing power of the English, that the government, as far as regarded the protection of the people, was dissolved. Neither the nabob nor his officers dared to offer any opposition to their sovereign will; and the tribunals of justice, so far from being a refuge to the oppressed, became subservient to the rapacity of the gomastahs, or Indian agents, employed by the Company's servants, and were converted by them into most efficacious instruments for oppressing and plundering the people.

The directors had been long dissatisfied with the proceedings of their servants, and with the produce of the land revenues, which had fallen far short of their expectations, and they now resolved to put an end to the double administration of the nabob and the Company; and, dispensing with the empty name of the former, to take upon themselves, ostensibly as well as really, the entire care and management of the land revenues. The dewanny of Bengal, Bahar, and Orissa, or the office of collector of the public revenues, which in the East implies the right of sovereignty, was conferred in perpetuity on the East India Company by a grant from the Mogul Shah Aulum, dated the 12th of August 1765. The assessment imposed on the country by Cossim Ali is stated by Sir John Shore to have been mere "pillage and rack-rent;" and it was an assessment on paper, as, out of the sum of L.2,882,724, there remained a balance undischarged of L.1,987,054, notwithstanding the cruelty with which the collection had been enforced. It was found necessary to reduce the assessment, in 1763–64, to L.1,991,785, out of which the sum realized was only L.857,070.[1] In 1764–65 the assessment imposed amounted to L.1,990,988. In 1765–66, the first year of the Company's administration, the assessment was 16,029,011 rupees, equal to L.1,803,263, of which 14,704,875 rupees (equal to L.1,654,298) were actually collected. In the two following years it was slightly increased, but deductions were afterwards made, as it was found impossible to collect it. Yet the sum actually realized was greater than ever was extorted from the country by all the cruelties of Jaffier Khan. But the methods by which it was collected were most ruinous. The landholders, failing almost universally in their engagements, were left to the mercy of the revenue-officers, by whom they were grievously oppressed. In many parts, the villages were deserted by the cultivators, and the land was left desolate. All these evils were still farther aggravated by a grievous famine which prevailed in Bengal in the year 1770, by which it is computed that about one-third of the inhabitants perished. But, in the midst of all this misery, the revenue was still violently kept up to its former standard. The deficiencies occasioned by the famine were re-assessed on those who survived this calamity; and so strictly were they levied, that the land revenue for that year exhibited an increase above that of the year preceding. The ruinous effects of this heavy exaction are stated at length in the different letters from the governor-general to the directors. In a letter, dated the 3d of November 1772, he observes, "It was naturally to be expected that the diminution of the revenue should have kept an equal pace with the other consequences of so great a calamity; that it did not, was owing to its being violently kept up to its former standard." He then describes the method by which this was accomplished, which was by "an assessment upon the actual inhabitants of every inferior division of the lands, to make up for the loss sustained in the rents of their neighbours, who are either dead or have fled the country." "The tax," he continues, "not being levied by any fixed rate or standard, fell heaviest on the wretched survivors of those villages which had suffered the greatest depopulation, and were of course the most entitled to the lenity of government. It had also this additional evil attending it, in common with every other variation from the regular practice, that it afforded an opportunity to the farmers, or shiedars, to levy other contributions off the people under colour of it, and even to increase this to whatever magnitude they pleased, since they were in course the judges of the loss sustained, and of the proportion which the inhabitants were to pay to replace it." To the same effect, Mr Middleton, one of the superintendents of the public revenue, observes, "When a very considerable portion, supposed even a third of the whole inhabitants, had perished, the remaining two thirds were obliged to pay for the lands now left without cultivators. The country has languished ever since, and the evil continues enhancing every day. The first remedy, without the adoption of which all other measures will be fruitless, is an universal remission of some considerable portion of the revenue throughout the provinces. Such remission should have been made immediately on the famine. Its not taking place then has made it more and more necessary every day; and the longer it is delayed, the more ruinous the consequences must be to this country and its revenue."

To correct these evils, supervisors, chosen from the Company's servants, were in 1769 stationed in different parts of the country, to superintend the native officers in the collection of the revenue and in the administration of justice; and two councils were appointed over the supervisors, one at Moorshedabad and another at Patna. These supervisors were instructed to procure information respecting the amount of the land revenues, the manner of collecting them, the amount of the cesses or arbitrary taxes, the origin and progress of those modern exactions, and also to inquire concerning the regulations of commerce and the administration of justice. The reports made by these supervisors concurred with all the other evidence received as to the wretched and oppressed state of the natives. "The nazims," they observed, "exacted what they could from the zemindars and great farmers of the revenue, whom they left at liberty to plunder all below; reserving to themselves the prerogative of plundering them in their turn, when they were supposed to have enriched themselves with the spoils of the country."

---

[1] See Sir John Shore's Minute, *Fifth Report*, p. 176.

It was now resolved to make a settlement of the land revenues for five years commencing from the year 1772. For this purpose, a committee of the board, consisting of the president and five members, named the "Committee of Circuit," was appointed, who were to make a journey through the country, and were empowered to receive proposals for a new lease of the lands, first from their ancient possessors, and if their offers were deemed unsatisfactory, they were to be let by public auction to the highest bidder. These persons proceeded in their circuit through the country, publicly advertising and letting in farm, for the highest rent that could be obtained, the estates of such as hesitated to contract for the assessment proposed. A great proportion of the landed property throughout Bengal was thus exposed to auction; and, in the general sale, the former owners and the great nobility of the country were outbidden by adventurers, to whom property was acceptable on any terms; and were generally dispossessed of their lands, from the surplus produce of which a provision was assigned them by the indulgence of the revenue committee.

The supervisors who had been stationed in the different districts were invested with the necessary powers for the collection of the revenue, and were henceforth denominated collectors. A native officer was to be joined with them under the title of duan, to confirm and to check accounts, and to assist in all those multifarious details which were intelligible only to a native. Various regulations were adopted to check the exertions of the collectors; but the governor and council express their regret that it was not in their power wholly to remedy this evil. Under the Mogul government, the duty of collecting the revenues and of administering justice was united, as formerly mentioned, in the person of the zemindars. The new scheme for the management of the revenues subverted this ancient order of things. The zemindar was superseded both as collector and as judge, and his place was supplied by two courts, the one for civil, called the Dewanny Court, the other, called the Fonjdarry Court, for criminal proceedings, established in each district. In the criminal court the new collector of taxes was to act as president, to be assisted by two Mahommedan officers, the cauzee and the muftee, and by two Mohlavies, as interpreters of the law. The civil court consisted, in like manner, of the collector as president, assisted by the duan and other officers of the native court. Two supreme courts were, at the same time, established at Calcutta, for the review of the inferior courts, the one for civil cases, being called Dewanny Sudder Adawlut, and the other the chief court of criminal justice, or Nizamut Sudder Adawlut. To one of these all capital cases were reported, and were ultimately referred to the governor and council, who, finding the labour too great, restored, in 1774, this branch of administration to the nominal nabob, and carried back the court to Moorshedabad. It appeared that, for a long period before this, the administration of criminal justice was wholly at a stand. In the new arrangements all disputes about property not exceeding ten rupees in value were referred to the head man of the district to which the parties belonged.

In considering those regulations, the question naturally occurs, how these supervisors, who were now to act in the double capacity of collector and judge, became qualified for the discharge of such important functions. In all other countries, it is only by a previous course of laborious preparation that any one is qualified for the office of a judge; and to appoint an unqualified person would be reckoned both dangerous and absurd. But how much more dangerous and absurd was it to appoint uninstructed persons to act as judges in a foreign land, with whose language they are but imperfectly acquainted, and of whose laws, manners, and customs, they are thoroughly ignorant? If, among a comparatively rude people, the mode of proceeding be loose and arbitrary; if there be no books of written law, or of precedents to govern judicial decisions, which must consequently depend on the imperfect lights and analogies afforded by manners, religion, or customs, the incapacity of a foreigner for the discharge of such nice duties becomes even more glaring. By disposing of the administration of justice in this manner, it was clear that the judicial duties would either be neglected, or that they would still be performed as before, and with no increased chance of amendment by native officers. This new arrangement was, therefore, like many others, a useless innovation on the established practice of the country. There is another weighty objection to the union in one person of the duties of collector and judge, namely, that it was in the collection of the duties that the grossest oppression had been committed; the powers of the collectors being frequently perverted to the most iniquitous ends. Under this new project, those who sought redress from the courts of justice met with their oppressor in the capacity of judge. He judged in his own case, and of complaints brought against his own conduct. Justice was in this manner an empty name, unless it was supposed that the judge would pronounce himself an oppressor.

Under the five years' lease on which the land revenues had been farmed in 1772, the country was grievously overtaxed. The revenues fell into a heavy arrear the very first year, and the lands were let on a progressive rent. To collect the outstanding balances, and to force up the revenue to its standard, a host of extortioners was, under the name of aumils, or collectors, let loose upon the afflicted country. But the rents contracted for by the farmers of the revenue were greater than they could pay, and, notwithstanding all their efforts, the arrears continued to increase. On the five years' lease, they amounted to a sum equal in value to L.1,454,277, which was judged to be wholly irrecoverable; while, during the same period, the sums remitted, even under the rigorous management of public farmers, amounted to L.1,336,451. Nor was this the only evil arising from the mal-administration of the Company's servants. The zemindars, who are admitted on all hands, even by those who advocate the sovereign's right to the possession of the soil, to have lived in splendour on their hereditary possessions; in all cases to have possessed the powers of magistracy within their district, and, where the territory was large, to have exercised a species of sovereignty; were either despoiled of their estates, or, where they were induced, by a hereditary attachment to their possessions, to engage for the rent proposed, they were overwhelmed with taxes which they could not pay, and were thus involved in poverty and ruin. Where the zemindar was himself the farmer of the revenue, he exercised the same extortion on his inferiors which was applied to himself; where a money-jobber, having no interest whatever in the property of the tenants, was the farmer, there was no limit to his extortion and cruelty.

The defects in this system for the administration of the land revenues soon began to disclose themselves; and the rulers of India, whose government was one continued innovation, immediately resolved to make another considerable change in the state machinery which they had just set in motion. They abolished the superintendence of the collectors; and the country, with the exception of Chittagong and Tipperah, being formed into six grand divisions, viz. Calcutta, Burdwan, Moorshedabad, Dinazepore, Dacca, and Patna, a council was appointed for each of the last five, consisting of a chief and four senior servants, to whom were transferred the powers and duties of the collectors. They were to preside in the courts of justice, and to superintend the collections; and, in subordinate districts, they delegated their powers to naibs or aumils, who were natives, and who were appointed, like their superiors, to collect and to judge in all cases under the value of 1000 rupees. The empty privilege of appeal was, as formerly, reserved to the unsuccessful suitor in the provincial courts; and, to superintend the whole collections of the country, a grand revenue-office was established at the presidency. The district of Calcutta was placed under the peculiar superintendence of a committee of revenue, consisting of two members of the council and three inferior servants. These regulations, which were declared to be temporary, and only preparatory to something more permanent, failed as usual in all their important objects. The defective administration of justice amongst the natives was admitted and complained of by all parties, and the peace of the country was in consequence disturbed by the general prevalence of robbery and other enormous crimes. The truth is, that the new arrangements had subverted the ancient institutions and local manners of the country, and had thus left a void in its internal economy which the government was in vain endeavouring to fill up.

The lease of the lands expired in 1777; and, after various suggestions and consultations, it was resolved that the rent should be regulated by the average collections of the three preceding years, and that the lands should be let, not by auction, but by an agreement with their ancient possessors in preference to other competitors. The liberal views of Mr Francis, who proposed that, in lieu of the monopoly of salt and opium, a moderate duty should be imposed on those articles, and that a long series of oppression should thus be terminated, by giving freedom to trade, were rejected by the governor-general. In pursuance of the plan proposed, the lands were let from year to year until the necessary arrangements could be completed for the system which was now to be adopted of a permanent land-tax.

The attention of the British parliament had frequently been directed to the state of our Indian possessions, and to the transactions of the resident government; and, in 1784, a new system, of which we have already given an account, was established in Britain for the control of the local administration, under which Lord Cornwallis, who was chosen governor-general, was specially directed by the act of parliament, as well as by instructions from the directors and the board of control, "to inquire into the alleged grievances of the landholders, and, if founded in truth, to afford them redress; and to establish permanent rules for the settlement and collection of the land revenue, and for the administration of justice, founded on the ancient laws and local usages of the country."

Lord Cornwallis, on his arrival in India, did not deem matters fully ripe for the execution of the proposed plan, namely, the permanent settlement of the land revenue. On this important subject he found that the most intelligent of the Company's servants differed widely in opinion. Neither the nature of the land tenure, nor the rights of the different orders of people who shared amongst them the produce of the soil, were well understood. All that was distinctly known was the amount of the revenue; but whether it was too high or too low was still a disputed point amongst the English in India, although the country was visibly declining under the weight of assessment. In such diversity of opinion, the governor-general, anxious to proceed with caution, delayed for a little the plan of a permanent settlement. He let the lands, in the mean time, from year to year, through the agency of the district collectors; and information on which to found a more durable arrangement was diligently sought from every source.

Permanent settlement of Lord Cornwallis.

In 1789, Lord Cornwallis had resolved on the permanent settlement of the land revenues. This he conceived to be essential to the relief of the country, the condition of which he described to be wretched in the extreme. "I am sorry," he observes, "to be obliged to say, that agriculture and internal commerce have for many years been gradually declining; and that at present, excepting the class of shroffs and banyans (bankers and merchants), who reside almost entirely in towns, the inhabitants of these provinces are advancing hastily to a general state of poverty and wretchedness. In this description I must even include every zemindar in the Company's territories, which, though it may have been partly occasioned by their own indolence and extravagance, I am afraid must also be in a great measure attributed to the effects of our former system of management." "I may safely assert," adds he, "that one third of the Company's territory in Hindustan is now a jungle, inhabited only by wild beasts." In pursuance of his plan, Lord Cornwallis entered into a permanent settlement of the land revenues for ten years, which was afterwards declared unalterable; and the zemindars of Bengal, Bahar, and Orissa, were formally constituted legal and perpetual proprietors of their respective estates, on the payment of a fixed rent to the state. The ten years, or, as it is called, the *decennial settlement*, was completed in every district in 1793.

In thus excluding itself from any prospective increase of revenue by limiting its demand upon the zemindar, there can be no doubt that the government committed a grave error. One of the great results of the measure was to elevate the zemindars from the grade of revenue-agents to that of landlords; but it never could have been the intention of government to increase the old zemindary allowance of 10 or 15 per cent. to above 100, and yet this has been the result of the permanent settlement. Mr Holt Mackenzie produced before the Commons' committee of 1832, a statement showing the aggregate government demand on various estates within certain districts of Bengal, farmed by the court of wards on account of minor and other disqualified zemindars, the rent paid by the farmer, and the profit accruing to the ward. The result shows a profit on the whole of rather more than 100 per cent. If some portion of this vast overplus were appropriated to recruit the government revenue, and the remainder permitted to remain in the pockets of the cultivators, both the state and its subjects would be greatly benefited. This, however, cannot take place on account of the existing settlement. It must be recollected that this income is not to be regarded as the rent of a landlord but the profit of a collector. Never was service so magnificently requited by any government as the collecting the revenue in India under the permanent settlement. One estate particularized in Mr Mackenzie's paper, is situated in the Twenty-four Pergunnahs, where the settlement was made upon a detailed measurement. On this property the share of the government is 6625 rupees; that of the zemindar 1976. The profit here, though very ample, falls far short of the average. Of course, there are other instances in which it is very much above the average. One of these is in the district of the Jungle Mehals, where the government revenue is 3654 rupees, and the zemindar's profits no less than 16,023 rupees. The settlement was obviously made in a state of great ignorance on the part of the government as to the real amount of the land revenue payable by the cultivators; and in consequence, the zemindar's payment was, in many instances, fixed at a sum quite inadequate. Another cause for the great excess of the zemindar's receipts over their payments to government, arises from the further occupation of waste lands since the settlement; an advantage which was surrendered by government as imprudently as unreasonably.

There was another defect in the decennial settlement, that it provided no security for the under-tenants and ryots in the hereditary privileges which they claimed in the soil. As they varied in different places and depended on different rules, the subject appeared to involve details too intricate for European management; and the important task of settling with the ryots was, therefore, devolved upon the zemindars, with a mere general recommendation to be guided by the custom of the place, and to give the ryot a written copy of his lease. According to this plan, it was the great proprietors only who had any permanent interest in the lands, while the inferior proprietors and tenantry were at the mercy of the principal landholders, who might exact from them whatever they pleased. The under-tenants and cultivators, in this ill-defined state of their rights, had no interest whatever in the improvement of the soil, being well assured that they would in no case be left more than a bare maintenance; and this was one among the other errors of the settlement, that it was made entirely with the zemindars, who were notoriously ignorant, oppressive, and corrupt. Maliks and other inferior landholders were crushed, and the just titles of the talookdars and ryots were extinguished; they were placed in the power of the zemindars, on whom alone the government relied for the improvement of the country, but many of these were capitalists who entered on the office of zemindar in the spirit in which they embarked in a mercantile speculation, and whose only object was of course to make the largest profit on their outlay. They were often unacquainted with the habits, the feelings, the wants, and even the language of the cultivators. Many, moreover, were purchasers who were destitute even of the recommendation of commercial respectability. It is represented that banyans, money-lenders, menial servants of Europeans, vakeels, and other retainers of the courts of law, seized the opportunity of elevating themselves in society by purchasing into this new aristocracy.

Consequences of the tax.

The producers of agricultural wealth being thus divested of their rights, frequently combined to keep down cultivation, and force the zemindar to give up the estate. It soon appeared, that, in order to realize the revenue, it would be necessary to sell the lands; and this evil once begun, continued to increase. The revenue was not punctually paid; and, for the recovery of outstanding balances, lands to a great amount were at stated times exposed to auction. In the year 1796–97, the lands advertised for sale bore a rent of 2,870,061 sicca rupees (L.332,927); and those actually sold yielded an annual rent of 1,418,756 rupees (L.164,576). In 1797–98, the quantity of lands sold bore a rent of 2,274,076 rupees (L.255,833); and it is observed in the Fifth Report, p. 56, that "among the defaulters were some of the oldest and most respectable families of the country;" "the dismemberment of whose estates," continues the Report, "at the end of each succeeding year, threatened them with poverty and ruin, and, in some instances, presented difficulties to the revenue officers in their endeavours to preserve undiminished the amount of the public assessment." In order to check those evils, several alterations were made from time to time by Lord Cornwallis. But they appear to have been unavailing; and, in the year 1802, in a report from one of the collectors, we have the following melancholy picture of the state of the country:—" 'All the zemindars,' it is observed, 'with whom I ever had any communication, in this and in other districts, have but one sentiment respecting the rules at present in force for the collection of the public revenue. They all say that such a harsh and oppressive system was never before resorted to in this country; that the custom of imprisoning landholders for arrears of revenue was, in comparison, mild and indulgent to them; that though it was no doubt the intention of government to confer an important benefit on them, by abolishing this custom, it has been found by melancholy experience, that the system of sales and attachments, which has been substituted for it, has, in the course of a very few years, reduced most of the great zemindars in Bengal to distress and beggary, and produced a greater change in the landed property than has perhaps ever happened, in the same space of time, in any age or country, by the mere effect of internal regulations.'[1] In another part of the same document, the collector, after commenting on a regulation then recently introduced, observes, 'Before this period (1799), complaints of the inefficacy of the regulations were very general among the zemindars, or the proprietors of large estates; and it required little discernment to see that they had not the same powers over their tenants which government exercised over them. It was notorious that many of them had large arrears of rent due to them which they were utterly unable to recover, while government were selling their lands for arrears of assessment.' The collector adds, 'Farmers and intermediate tenants were, till lately, able to withhold their rents with impunity, and to set the authority of their landlords at defiance. Landholders had no direct control over them; they could not proceed against them, except through the courts of justice; and the ends of substantial justice were defeated by delays and costs of suit.' " To the same purpose Sir Henry Strachey observes, "That the men of opulence are now all men of yesterday; that the greatest men formerly were the Musulmen rulers, whose places we have now taken, and the Hindu zemindars. These two classes are now ruined and destroyed."[2]

The ruin of the zemindars was partly occasioned by another cause, namely, the want of any effectual method of enforcing their claims against the small tenants. The public officer was empowered to proceed against defaulters by a summary process, and to attach and sell, by public auction, the zemindar's land for the discharge of arrears; whilst against the under-tenants the zemindar had to seek redress by an ordinary suit at law, which was both tedious and expensive. To heighten this evil, the courts of justice were overloaded with a long arrear of undecided causes, so that no decision could be expected before the lapse of years. There were in the district of Burdwan above 30,000 undecided suits; and no decision could be expected within the ordinary duration of human life. The zemindar, in this manner, whilst he was compelled to pay, by the prompt and efficient process of government, was left to seek redress from his tenants through a labyrinth of endless litigation; and the knowledge of this impediment to justice gave great encouragement to the tenants to refuse payment of their rents. The ruin of the zemindar, therefore, was the inevitable consequence of this summary process to which he was exposed, while he could have no similar recourse on his tenants; and these regulations were universally complained of, and on the justest grounds. In an address from one of the collectors to the board of revenue, in behalf of the zemindar of Burdwan, who had in vain ap-

Hindustan.

plied for redress to the civil courts, it is observed that he (the zemindar) begs leave to "submit to your consideration, whether or not it can be possible for him to discharge his engagements to government with that punctuality which the regulations require, unless he be armed with powers as prompt to enforce payment from his renters, as government had been pleased to authorize the use of in regard to its claims on him; and he seems to think it must have proceeded from an oversight, rather than from any just and avowed principle, that there should have been established two modes of judicial process under the same government; the one summary and efficient for the satisfaction of its own claims, the other tardy and uncertain in regard to the satisfaction of claims due to its subjects; more especially in a case like the present, where ability to discharge the one demand necessarily depends on the other demand being previously realized."

Oppression of the ryots.

The system which impoverished the zemindars proved equally ruinous to the ryots. It was the practice of the zemindar to contract for a certain rent with a land farmer, who subdivided the land into smaller portions, and let it to a variety of inferior tenants. To this head farmer it appears that a written agreement was given, according to the regulations; but the under-tenants were left, without any security, to the mercy of their superiors. It is well known, and admitted by the servants of the Company, that the ryot, even when he receives written agreements from the zemindar, is liable to indirect oppressions which no law can remedy; and though, owing to the expense and delay in the administration of justice, he could retaliate on the zemindar, by refusing payment of his rents, this privilege could be of little advantage to him, whilst it tended still farther to widen the breach between the landlord and the tenant, and to add to the hatred, strife, and violent destruction of interests by which the community was now, as it were, torn in pieces. To remedy the grievances which the zemindars suffered from the evasion of payment by their tenants, it was enacted in 1799 that they might have recourse to the same summary process against defaulters as was used by the government against themselves. They were empowered to seize the property of their tenants for arrears, previous to any legal judgment, or any proof of the justice of their claim. This regulation gave to the zemindars the power of unbounded oppression, against which the ryot had no redress, as he was effectually shut out of the courts of justice by the enormous expenses of law proceedings.[1] It was undoubtedly just that the zemindar should have the same efficient process for enforcing payment as was used against himself; but such was the unhappy condition of India, under the unskilful management of strangers, that every plan of reform seemed only to increase the general disorder. Her rulers wanted intelligence for the delicate task of domestic legislation; their schemes were crude and inapplicable, nor could they ever mould the various and jarring interests of the Indian community into any consistent scheme of civil order; so that, though they were continually patching their imperfect work, it still bore the same incongruous character, and the cure of one evil was constantly followed by an irruption of other and worse evils from some other quarter.

Notwithstanding these obvious evils, attempts have been made to repeat the unsuccessful experiment of a permanent settlement by extending it to the western provinces. These were in the first instance frustrated by the objections of Mr Cox and Mr Henry St George Tucker, who were appointed commissioners for carrying the plan into effect. It is remarkable that both these gentlemen were advocates for the system; but on being deputed to superintend its establishment in an untried spot, they perceived that objections existed to its introduction; and these they had the manliness and candour freely to point out. But, notwithstanding their representations, the Bengal government persisted in its determination to introduce the permanent settlement; and the commissioners, finding their views thus at variance with those of the supreme authority, felt themselves called upon to resign. The home government appears to have taken a view of the subject more just, calm, and statesmanlike than that of the local government, and, in the words of Mr Sullivan, "uniformly evinced throughout the whole correspondence on this grand question fully as strong an anxiety that the rights of individuals should not be infringed, as that the interests of the state should not be compromised by a premature discussion." A termination was put to the proposed extension of the system in 1817, when the board of control and the court of directors, after ample discussion, finally agreed upon the following points:—

"That the system of 1793, though originating in the most enlightened views and the most benevolent motives, and though having produced considerable good, has nevertheless been attended in the course of its operation with no small portion of evil to the people for whose happiness it was intended.

"That the same views and motives which dictated the original introduction of the permanent settlement twenty-five years ago, would not, after the experience which had been had of it, justify the immediate introduction of the same system into provinces for which a system of revenue administration is yet to be settled.

"That the creation of an artificial class of intermediate proprietors between the government and the cultivators of the soil, where a class of intermediate proprietors does not exist in the native institutions of the country, would be highly inexpedient.

"That no conclusive step ought to be taken towards a final settlement of the yet unsettled provinces, until it shall have been examined, and if possible ascertained, by diligent research and comparison of collected testimonies as well as by accurate survey of the lands to be settled, how far the principle of a system which would bring the government into immediate contact with the great body of the people, can be practically and usefully applied to them."

This decision was dictated by a sound policy. The attempt to create a landed aristocracy was from first to last based upon erroneous views. Had it been practicable, it could not be effected without the destruction of a mass of private rights, which it was the duty of the law to protect instead of subverting. The observations of Mr Campbell, of the Madras civil establishment, on this point are just and convincing. "In India," says he, "where the only aristocracy connected with the land are the mere hereditary farmers-general, or contract-agents of the government—and the soil itself is invariably occupied by a numerous class of petty proprietary cultivators—it was obviously impracticable to introduce the European theory of landlord and tenant without an infraction of individual rights. It never ought to have been, nor can it now even justly be, made a question for consideration or decision whether in India it be politic to give the preference to great or to small holders of land. The law and usage of the country have immemorially and irrevocably determined the right in the soil to be vested in particular classes. Whatever may be the extent or value of such right, the smallest no less than the greatest tenure should be held inviolably sacred; and the rights of millions of field proprietors to hold on defined terms directly of the state never can be abrogated for a mere theoretical improvement in the administration of the land revenue, without an act of the most sweeping confiscation ever hazarded by a civilized government. It was clearly the duty of a just government anxiously to protect all existing rights; and by defining its demand on the possessor of each tenure holding immediately of the state, to maintain every class in its respective situation, and to ensure the benefit of any remission or reduction in its land revenue to those who pay it, instead of allowing it to be intercepted by its intermediate revenue contractor, the zemindar."

---

[1] All the collectors invariably bear testimony to the oppressions of the zemindars after the passing of the regulation of 1799.

But had there been no previous rights in the way, the attempt suddenly to call into existence an aristocracy whose claims were based neither on property nor ancient usage, would have failed. The plan, indeed, was nowhere distinguished by even the semblance of success, except in the districts where the zemindar's authority was continued in its ancient line; and in these cases that part of the plan which subjected the zemindar's right to sale in case of default was productive of the most serious mischief. Under the native powers it was not the practice to sell the zemindar's right. The zemindar himself was subject even to corporeal punishment, but his right was never brought to sale. The enforcement of such a system consequently outraged the feelings of all classes, where the institution was ancient; and the description of persons whom the sales frequently introduced to the exercise of the zemindary authority was little calculated to allay the feelings of irritation excited by the forcible expulsion of an old family.

The state of society which prevailed in Hindustan arose from the mixed operation of a peculiar system of laws, customs, manners, religion, and policy; and such an artificial structure required to be nicely and skilfully handled, instead of which it was lacerated in all its delicate parts by the rude hand of foreign interference. The English were ignorant even of the language of the people whom they had brought under their sway, and whom they now attempted to govern; and though they might know generally that the public revenues were derived from an impost on land, they were entirely inexperienced in the usages of the country, and in the financial details of the Mogul government. With what effect, therefore, could they interfere in such complicated details? how could they decide between the claims of justice and of fraud? how could they judge of cases connected with the peculiar usages of the country, and with all those minutiæ of local manners with which no foreigners can ever become thoroughly acquainted? The Company's servants, involved in such a labyrinth of complex concerns, possessed no clue to guide them to any equitable issue. Supposing their views to have been honest, they wanted intelligence to give them effect; and although they could enforce submission to their decrees, the country, under their usurped and ill-directed authority, presented one vast scene of anarchy and oppression. The directors in Europe readily ascribed all these evils to the misconduct and rapacity of their servants, which they heavily censured; and, in their correspondence with India, they express the most just, humane, and enlightened sentiments, and a sincere desire to promote the happiness of their subjects. But if they had only said to their servants "lower the assessment," these three words would have been of more avail than volumes of fine sentiment. The glory of a sovereign consists in the felicity of grateful millions, and this is the only true and legitimate end of all government. But the East India Company were intent on profit, on enriching themselves at the expense of their subjects; and the duty of the servants to their masters consisted in sending home a large investment. They were to possess themselves of as large a quantity as possible of the produce of the country, giving nothing in return, and to send it to Europe to be shared amongst the proprietors; and it was, accordingly, the boast of successive administrations how well they had succeeded in this matter; not how happy they had made their subjects, but how much of their property they had taken from them and sent to Europe.

Judicial system of Lord Cornwallis.

The institutions of Lord Cornwallis for the administration of civil and criminal justice appear to have been equally unsuccessful with his finance measures; and it soon appeared, as has already been stated, that the new courts of judicature had more business than they could manage, and such an arrear of undecided cases accumulated that the course of justice was nearly stopped. In this dilemma, the costs of suit were raised for the purpose of discouraging litigation; and this expedient being found ineffectual, they were raised a second time. To place justice out of the reach of the poorer and more numerous class, by laying a heavy tax on it, was indeed an easy and effectual method of discouraging litigation. It was, in fact, a denial of justice, a direct refusal to hear the complaints of the poor, who might, therefore, be harassed for ever after with impunity. Notwithstanding this discouragement, however, the evil went on increasing, and at last amounted to an almost total dissolution of civil order. As no decision was to be procured before the regularly-constituted tribunals, every man began to arm himself in his own quarrel; and the country thus became the scene of bloody affrays between armed individuals, unhappily left without any other resource for the decision of their differences. In some of those conflicts 4000 or 5000 persons were arrayed on each side, and many lives were lost. In a letter of the court of directors, dated October 1814, it is observed, "As to affrays respecting the possession and boundaries of lands and rents, this has been long a serious evil, and must, we conceive, have existed in a greater or less degree in every part of the country." "These affrays," continue the directors, "which often lead to homicides and woundings, have been very naturally ascribed by several of the judges to the difficulty of obtaining judicial redress."[1] In the district of Tirhoot, where the public peace had been frequently disturbed by those private feuds, the judge for the division of Patna observes, that they chiefly "arose from the accumulated arrears of suits," and "that the parties finding a delay in obtaining redress, had resorted to force."[2] Mr Melville, also a judge in the division of Dacca, expresses himself to the same purpose. "With respect to affrays," he observes, "attended with homicides and wounding, it is known that those disorders arose from attempts to retain by force possession of lands, or rents of lands, to which the different parties alleged separate claims." The same person afterwards states, that "in Chittagong, they (meaning these quarrels) had not only been frequent, but violent; that the police authority had been often resisted, and in one instance overpowered; that it would be wrong to disguise the length of time a claimant must wait, with the sacrifices he must make, before the decision of a civil court can be obtained."

Penal judicature and police

We shall now briefly advert to the system of penal judicature and police established by Lord Cornwallis; the object, in this case, being to give security to the people by the suppression of crimes. With reference to this object, however, the scheme has notoriously failed. Since the year 1793, India has become a prey to disorders of every sort, and to the worst of crimes. The crime of robbery, accompanied with murder, rose to a most alarming height, and was prosecuted with a degree of union, perseverance, and cruelty, inconceivable to those who live in the civilized communities of Europe. Robbery at this time was a regular profession, handed down from father to son; and the decoits, or gang-robbers, were formed, as the title implies, into powerful confederacies, and made their irruptions on the peaceful country with a force which it was vain to resist. They are described by Mr Hastings as "a race of outlaws, who live from father to son in a state of warfare against society, plundering and burning villages, and murdering the inhabitants." In the year 1772, the robbers are mentioned by the committee of circuit, and stated to be "not like robbers in England, individuals driven to such courses by sudden want; they are robbers by profession, and even by birth; they are formed into regular communities, and their families subsist by the spoils which they bring home to them."

Increase of crimes.

All the reports of the judges employed in the administration of criminal justice concur in representing the deplorable prevalence of the atrocious crimes of gang-robbery and murder. Sir Henry Strachey, writing on this subject in 1802, observes, that the crime of decoity (that is, robbery by gangs) has increased greatly since the British administration of justice. Another judge, writing on the same subject in 1808, observes, "That decoity (gang-robbery) is very prevalent in Rajeshahye has been often stated. But if its vast extent were known; if the scenes of horror, the murders, the burnings, the excessive cruelties, which are continually perpetrated here, were properly represented to government, I am confident that some measures would be adopted to remedy the evil. Certainly there is not an individual belonging to the government who does not anxiously wish to save the people from robbery and massacre." (*Mill*, vol. iii., p. 311.) He afterwards adds, that such is the state of things which prevails all over Bengal; and as to his own particular district, he expresses his persuasion that no civilized country ever had so bad a police. To the same purpose Mr Dowdeswell, the secretary to the government in 1809, observes, in a report which he drew up on the general state of Bengal, "Were I to enumerate only a thousandth part of the atrocities of the decoits, and of the consequent sufferings of the people, and were I to soften that recital in every mode which language would permit, I should still despair of obtaining credit, solely on my own authority, for the accuracy of the narrative." "Robbery, rape, and even murder itself," continues he, "are not the worst figures in this horrid and disgusting picture. An expedient of common occurrence with the decoits, merely to induce a confession of property, supposed to be concealed, is to burn the proprietor with straw or torches, until he discloses the property, or perishes in the flames. And when they are actuated by a spirit of revenge against individuals, worse cruelties, if worse can be, are perpetrated by these remorseless criminals. If the information obtained is not extremely erroneous, the offender, hereafter noticed, himself committed fifteen murders in nineteen days; and volumes might be filled with the atrocities of the decoits, every line of which would make the blood run cold with horror." (*Fifth Report*, p. 603.)

It would far exceed our limits to trace in detail the cause of those evils which necessarily arose out of the very nature of the government now established. The truth is, the British were never qualified to act as legislators in India. They were too ignorant of the habits, manners, and character of the people, to meddle with their institutions, on which, however, they were continually innovating. By altering the old mode of settling the land revenues, they compromised the rights of the different classes of landholders and occupiers. Strife and contention immediately ensued, litigation burst upon society like a flood, the civil courts were overwhelmed with suits which they could not decide, and the people, desperate from a denial of justice, were involved in furious affrays with each other in prosecution of their rights, or, being driven from their lands, they had recourse to robbery for a subsistence. Business was thus, from various sources, accumulated in the criminal courts, which being encumbered with the delay, the expense, and all the tedious formalities of the English practice, proceeded with their decisions at much too slow a pace for the wants of the country; and the evil in this manner daily increased. The mischief of this delay was twofold,—1*st*, It allowed criminals, during the long interval between their apprehension and trial, to prepare the certain means of their escape, by the suborning of false witnesses, who, in the gross dissolution of morals in Hindustan, were always to be readily procured, and in any number; and, 2*dly*, It entailed a grievous hardship on the innocent, great numbers of whom were crowded into jails with the worst of felons, there to wait until the tardy hand of justice should bring them relief.

Defective police.

The inefficient state into which the police had fallen, was also one cause of the general prevalence of crimes. By the ancient institutions of the Mogul government ample means were provided for the preservation of the public peace. In every village a permanent body of guards and watchmen was maintained, whose business it was to assist in all the subordinate details both of the revenue and police, to convey the rents of the ryot to the district collector, to watch those ryots who were in arrear, to guard their crops from depredation, to act as guides and protectors to travellers, to collect information of any offences committed, and to report the arrival in the villages of suspicious persons. For these various services they had grants of land rent-free, or on very easy terms. Besides this standing force of guards and village watchmen, the zemindar, who was at the head of the police, and was held responsible for all crimes committed within his boundaries, had under his orders a large body of *pykes*, or armed constables, whom he could call out in aid of the police service, either for the apprehension of offenders, or to prevent breaches of the peace. These establishments, though they had fallen into a state of decay at the time of the permanent settlement in 1793, and though they were frequently perverted from their original purposes, yet existed in all parts of the country, and the police force was found to be in great efficiency and strength. The zemindary of Burdwan, a tract of country seventy-three miles long by forty-five broad, which was in the highest state of cultivation, and well stocked with inhabitants, maintained a body of 2400 village watchmen, who were distributed under their respective chiefs amongst the different villages, for the double purpose of protecting the inhabitants and of procuring information; besides 19,000 *pykes*, or armed constables, who were liable to be called out, under the orders of the zemindar, in aid of the police. Instead of improving upon those ancient establishments which had taken root in the country, which were interwoven with the frame and texture of Indian society, and which were, generally speaking, efficient, though frequently perverted from their original purposes, Lord Cornwallis demolished the whole structure. According to his new scheme of police, the zemindary constables were disbanded, and their lands, which were allowed them in lieu of pay, were resumed, that is, were seized by government. The country was divided into districts of twenty miles square, over which a native police officer or darogah was placed, with fifteen or twenty armed men under his orders; he was assisted also by the village watchmen, and such of the zemindary constables as were still retained in the public service. It was soon found, however, that the new police officers could not effectually call out this array in aid of the civil power. They wanted the personal consideration of the zemindars, who had long been looked up to with respect and reverence as the hereditary aristocracy of the country. The system, therefore, proved eminently inefficient; nor were the officers employed under the new plan found to be less corrupt than the disbanded constables of the zemindars. The merits of the plan appear to be pretty fairly estimated in the Fifth Report (p. 71), in which it is observed, that the head police officers, and "the inferior officers acting under them, with as much inclination to do evil, have less ability to do good than the zemindary servants employed before them." How vain was it to imagine that any better materials could be found for the regulation and government of the country than those which the country itself afforded. To complain of them was to complain of the general state of society out of which they were produced; and to throw them away because they were corrupt or otherwise imperfect, evinced an ignorance of the legislator's province, which is not to create materials, but to make the best use of those which are provided to his hand. Herein, then, consisted the error of the British legislators. They cast from them the only efficient instruments which were to be found for the government of the Indian community, while they had nothing to substitute in their place; and their plans, when tried in practice, were accordingly found to be idle theories, at variance with the whole frame and order of the society for whose use they were intended.

Prevalence of gang-robbery.

The pernicious consequences of thus rashly subverting the ancient establishments of the country were soon displayed in the alarming increase of crimes. The disbanded zemindary constables, whose lands were seized, were deprived of the means of living, and they necessarily betook themselves to theft and rapine for a subsistence. The country became infested with gangs of robbers and murderers, whose horrid cruelties struck terror into the peaceable inhabitants, whilst lesser crimes also became more frequent. The police was inadequate to the detection of offenders, the courts of justice to their conviction; and, amongst other evils, a host of false witnesses now arose, amid the general corruption of morals, who swore in the teeth of each other, perplexing all judicial proceedings, and confounding the innocent with the guilty. For remedy of these complicated evils various expedients were resorted to. Amongst others, a feeble attempt was made to revive the ancient powers which the zemindars had over the police; but this was attended with so little success that it was abandoned in 1810. In 1808 a superintendent of police was appointed, with a view, as was stated, of concentrating in his office all the information which might be obtained from different quarters, and of giving unity and vigour to the measures adopted for the apprehension of offenders; and, as a last resource, a regular establishment of police spies, called *goyendas*, was organized, and placed under a species of superintendents called *girdwars*, the office of the first being to point out the robbers, that of the latter to apprehend them. Notwithstanding all these measures crimes of every description appear to have gone on increasing; and in a minute of Lord Minto, dated November 1810, it is observed, "That a monstrous and disorganized state of society existed under the eye of the supreme British authorities, and almost at the very seat of that government to which the country might justly look for safety and protection; that the mischief could not wait for a slow remedy; that the people were perishing almost in our sight; that every week's delay was a doom of slaughter and torture against the defenceless inhabitants of very populous countries." The directors, in whose letter of the 28th of October 1814 this passage appears, confirm the truth of the statement by the following brief observation:—"That this representation of the late governor-general is not too highly coloured would appear from the minute of Mr Lumsden, and the reports of Mr Secretary Dowdeswell, forming also part of the proceedings in regard to Mr Earnst."[1]

Spies.

The new scheme of employing spies, however useful in some cases, was in other respects highly detrimental to the peace of the community. Those spies, and more especially their superintendents (*girdwars*), became, in many cases, the pests of society. They took advantage of the power which they possessed of apprehending suspected persons to extort money from them; and frequently, under threats of immediate apprehension, they laid under contribution all classes indiscriminately. It is stated, in a letter of the directors dated October 1814, on the authority of Mr Dick, a circuit judge, that "whole villages are put under contribution, or subjected to the rapacity and spiteful machinations of the vilest members of society."[2] In some cases the innocent were brought to trial, and convicted on suborned evidence, procured by these wretches.

Incapacity of European judges.

Amongst the other causes of these evils may be enumerated the incapacity of Europeans to officiate as judges in a society so peculiarly constituted as that of India. This is a fact which is deeply regretted by all the most experienced servants of the Company, from Sir John Shore downwards. In two essential qualifications for the judicial chair Europeans must always be surpassed by the natives of India. They can neither acquire the same familiarity with the vernacular languages, nor obtain the same keen insight into native character. The ruling authorities have not been insensible to these shortcomings, and a remedy has been sought in the more extensive employment of native agency, subject only to careful European supervision. Europeans mix little with the natives in their ordinary business or amusements; and when, under such disadvantages, they attempt to officiate as judges, they have always found the difficulty of appreciating or understanding even the most ordinary transactions of a society, with the rules and principles of which they are entirely unacquainted. What is intelligible by intuition to a native, is a mystery to them; and it is easy to conceive how these difficulties must be accumulated on them in any case involving a long train of circumstantial or contradictory evidence. It is not, as every one knows, on the mere naked testimony of a witness, that a judge entirely relies; it is the tone, the manner, the living evidence of expression and character, which impresses upon testimony the stamp of truth, which carries conviction to the mind, and saves a judge from the miserable dilemma of being blown about by every wind of opposite evidence. These discriminations are, however, far too nice for a European judge in an Indian court, and he frequently knows not what to believe. He cannot, by any judicious cross-examination, extort the truth from contradictory witnesses. In any train of questions involving the peculiar usages of the country, his stock of knowledge is soon exhausted. A story which hangs together in all its main circumstances may yet be inconsistent in some of its minute and delicate points. But a European can never detect inconsistencies which are wrapt up in the veil of local manners, and hence he lies at the mercy of every perjured witness who chooses to practise upon his ignorance. The truth of this statement is illustrated and confirmed by the concurring reports of many of those who have acted in this trying situation. Sir Henry Strachey, whose reports to the supreme government abound in most just, enlightened, and comprehensive views of Indian society and manners, observes, that "nothing is more common, even after a minute and laborious examination of evidence on both sides, than for the judge to be left in utter doubt respecting the points at issue. This proceeds chiefly from our very imperfect connection with the natives, and our scanty knowledge, after all our study, of their manners, customs, and languages. Within these few years, too, the natives have attained a sort of legal knowledge, as it is called; that is to say, a skill in the arts of collusion, intrigue, perjury, and subordination, which enables them to perplex and baffle us with infinite facility." "We perhaps judge too much by rule; we imagine things to be incredible because they have not before fallen within our experience. We make not sufficient allowance for the loose, vague, and inaccurate mode in which the natives tell a story; for their not comprehending us, and our not comprehending them. We hurry, terrify, and confound them with our eagerness and impatience." "We cannot," adds the same discriminating observer, "study the genius of the people in its own sphere of action. We know little of their domestic life, their knowledge, conversation, amusements, their trades and castes, or any of those national and individual characteristics which are essential to a complete knowledge of them. Every day affords us examples of something new and surprising; and we have no principle to guide us in the investigation of facts, except an extreme diffidence of our opinion, a consciousness of inability to judge of what is probable or improbable." "The evil I complain of is extensive, and, I fear, irreparable. The difficulty we experience in discerning truth and falsehood among the natives may be ascribed, I think, chiefly to our want of connection and intercourse with them; to the peculiarity of their manners and habits, their excessive ignorance of our characters, and our almost equal ignorance of theirs." The following passage, from the same document, gives a striking view of the inefficiency of European judges:—"The evidence on every trial convinces us, that innumerable robberies and murders, that atrocities of the worst conceivable kind, are committed, and that very often the perpetrators are before us; yet do we find ourselves, from causes of the nature above described, constrained to let them loose again to prey on society, or, at the utmost, to direct that they be discharged, on giving security for their good behaviour." "The judge of circuit is from day to day engaged in trying large gangs for robbery and murder, and letting them go; and the country continues to be overrun with them, to a degree truly deplorable."[1]

[2] *Papers printed by order of the House of Commons,* 1819.

In fact, a grave error had been committed in attempting to transact the public business of the country by means of European agency. This was the early practice of our Indian administration. The Marquis Wellesley, writing to the home authorities at the close of the last century, thus enunciates the principle:—"The duty and policy of the British government in India, therefore, require that the system of confiding the immediate exercise of every branch and department of the government to Europeans educated in its own service, and subject to its own direct control, should be diffused as widely as possible, as well with a view to the stability of our own interests as to the happiness and welfare of our own subjects." The experiment was fully tried, but resulted in disappointment, inasmuch as it was impossible to carry it out otherwise than very imperfectly, except at an enormous expense. Another mode, that of employing native agency to a large extent, was more readily available. Native functionaries might be obtained upon lower terms, and in some essential points they would enjoy advantages over Europeans. It was feared, however, that they could not be trusted; and if remunerated at the low scale formerly allotted to them, and unwatched by any superior, the apprehension was not unreasonable. The problem was to unite economy and despatch with efficiency and integrity; and the solution is found in the extensive employment of native agency, subject to careful European supervision. This has been tried, and works well. The change has taken place within the last twenty years, during which period several new offices of trust and emolument have been opened to the natives of India, and those previously allotted to them have been materially advanced both in emolument and responsibility. Civil justice, in fact, is almost wholly dispensed by native judges. They are distributed into three grades—principal sudder aumeens, sudder aumeens, and moonsiffs. The jurisdiction of the two lower grades is limited to suits in which the matter in dispute does not exceed a certain value, the limit being of course higher in regard to the upper of these two grades than to the inferior. To the jurisdiction of the highest native judge there is no such limit. To these different classes of native judges is entrusted the original cognizance of all civil suits; and no person, whether British or native, is exempt from their jurisdiction. The first grade of native judges (principal sudder aumeens) may sit in appeal from the decrees of the two inferior courts; and as the law, except in special cases, allows but one trial and one appeal, the power of final decision in by far the larger number of suits rests with native judges. Further, suits wherein the amount in dispute exceeds L.500 may be tried either by the principal sudder aumeen or by the European zillah judge, if he so please. But in either case an appeal lies only to the highest Company's court, the sudder adawlah. Here, then, the native judge exercises the same extent of jurisdiction as the European functionary. Native and British qualification and integrity are placed on the same level. The suits now entrusted to a head native judge were confided before 1837 to no officer below a European provincial judge. By recent enactments natives of India are eligible to the office of deputy magistrate. They are competent in that capacity to exercise the powers of the European covenanted assistant, and even, under orders of the local government, the full powers of magistrate. When entrusted with the latter, their power of punishment extends to three years' imprisonment, and they are also competent, in cases of assault and trespass committed by Europeans on natives, to inflict a fine to the extent of 500 rupees, and to imprison for the term of two months if the fine be not paid. Natives are frequently invested with full powers of magistrate.

Judicial establishments.

The judicial establishments of Bengal, over which European judges preside, are,—

1*st*, A high court of appeal, termed the sudder dewanny adawlut; and the nizamut adawlut, or the chief civil and criminal court, which sits in Calcutta, and is composed of judges selected from the civil servants of the East India Company. On the civil side this court has ceased to exercise any original jurisdiction, but it is the court of final appeal in the presidency, and controls all the subordinate civil tribunals. Besides regular appeals from the decisions of the European zillah judge, and in certain cases from those of the principal sudder aumeen, the court is competent to admit second or special appeals from decisions of the courts below on regular appeals. The grounds for special appeal are,—when the judgments shall appear inconsistent with law or the practice or usage of the courts. The power thus given to the sudder court of hearing special appeals extends their means of supervision, and brings judicially before them the proceedings and decisions of all classes of judicial officers, and affords opportunity for correcting errors and insuring consistency, it being one of their duties to regulate the practice and proceedings of the lower courts. Moreover, each judicial officer is required by law to record his decisions, and the reasons for them, in his own vernacular tongue, and this affords the sudder court extended means of judging correctly of the individual qualifications of their subordinates. The sudder court sits daily. In the trial of appeals the proceedings of the lower tribunals are read before one or more judges. A single judge is competent to confirm a decree. Two of three sitting together must concur for its reversal, whether the appeal be regular or special. Decisions of the court in suits exceeding in value L.1000 may be carried by appeal before the Queen in council. On the criminal side the court has cognizance in all matters relating to criminal justice and the police of the country, but it exercises no original jurisdiction. Appeals from the sessions judges lie to this court, but it cannot enhance the amount of punishment, nor reverse an acquittal. The sentences of this court are final. In cases of murder, and other crimes requiring greater punishment than sixteen years' imprisonment (which is the limit of the sessions judges' power), all the proceedings of the trial are referred for the orders of the nizamut. The Mohammedan law-officer of this court (unless the futwa be dispensed with) first records his judgment, and all the documents are then submitted to the judges of the nizamut. If the case be not capital, it is decided by the sentence of a single judge. Sentences of death require the concurrence of two judges. Trials before the sessions judge for crimes punishable by a limited period of imprisonment are also referred for the disposal of the nizamut in cases where the sessions judge differs from the opinion of the Mohammedan law-officer.

---

[1] Answers to Interrogatories of Government, 30th January 1802, *Fifth Report.*

2nd, The zillah courts, over which European judges preside and supervise the dispensation of justice by their native functionaries. It is competent to the European judge to withdraw suits from the courts below and to try them himself. He hears appeals from the decisions of his principal native judge when the matter in dispute does not exceed the value of L.500; but he may transfer appeals from the decisions of the other subordinate courts to the file of the principal native judge. In the sessions court the judge is required to try all persons committed for heinous offences by the magistrates. He has not the power of life and death, but his jurisdiction extends to sixteen years' imprisonment. All capital cases, after trial, must be referred for the disposal of the nizamut adawlut, together with those cases, as already intimated, in which the sessions judge dissents from the opinion of his Mohmamedan law-officer. Persons not professing the Mohammedan faith are not to be tried under the provisions of the Mohammedan law, but under the regulations, the judge being assisted by a punchayet, or assessors, or a jury, but having power to overrule their opinion. The sessions judge holds a monthly jail delivery, though in fact he may be said to be constantly sitting. He sits in appeal from the sentences passed by the magistrates and their assistants. A similar plan of jurisdiction is in force at Madras and Bombay.

At each presidency there is a supreme or Queen's court, in which the judges are appointed by the crown, and the modes of procedure are assimilated to those of the courts at Westminster. In conclusion, it may be observed that the judicial system of India is necessarily one of most heterogeneous character, and it must probably continue so for a period of which the duration cannot be anticipated. The law of the Hindus is founded upon their religion. It is of course in many respects barbarous and absurd. It is also sometimes extremely vague, and on the whole very imperfect. The Mohammedans introduced their law, which, like that of the Hindus, was closely connected with their religion. The settlement of the British created a necessity for the introduction of a system of law differing from either. The law of England thus obtained a footing in India, but it did not altogether supersede either of the systems which it found previously in operation. But the Hindu and Mohammedan codes were such as no European people could consent to administer; they were therefore modified in practice, and, while their leading principles were adhered to, their more barbarous provisions were softened or rejected. Circumstances also continually arose to show the necessity of some additional rules for the administration of justice; and the governments of India from time to time enacted various regulations, which, unless annulled by the authorities at home, have the force of law. The principles of judicial administration in India are consequently derived from no fewer than from four different sources,—the institutions of the Hindus, those of the Mohammedans, the English law, and the regulations of the Indian governments.

The permanent zemindary settlement was extended to Benares in 1795. It has been seen that the attempt to introduce this system into the north-western provinces was delayed in the first instance by the objections of the commissioners, which, however, were directed not against the principle, but the time and local circumstances of its application; and that it was finally suspended by a solemn decision of the home authorities. This was indeed a fortunate circumstance; and we may ascribe to it the fact that the landed estates in these provinces remain in the hands of the true proprietors, and that rapacious intruders have not become lords of the soil. A revenue settlement, based upon a careful survey, has now been effected. Under this settlement, the rights of every cultivator, whether landlord or tenant, have been ascertained and recorded; and, for the protection of these rights, a system of registration of titles to land has been introduced. The government assessment, calculated upon the basis of two-thirds of the net rent, has been fixed for a period of thirty years. By this limitation of the public demand a valuable and marketable private property has been created in the land, and every landholder, however petty his holding, is to a certain extent a capitalist. The following table exhibits the amount of land revenue, together with the population, area, and other particulars relating to these provinces:—

NORTH-WESTERN PROVINCES.

Number of Townships		80,883
Area in Acres		46,070,658
LAND ASSESSED TO REVENUE,—	Acres.	
Cultivated	23,112,183	
Culturable	9,816,749	
		32,928,932
LAND UNASSESSED,—		
Rent Free	1,733,443	
Barren	11,408,283	
		13,141,726
Total area in Acres		46,070,658
		Rupees.
Demand on account of Land Revenue		405,29,921

	R.	A.	P.
Rate per Acre on Total Area	0	14	1
On Total Assessed Land	1	3	8
On Total Cultivation	1	12	1

POPULATION.

HINDOO,—		
Agricultural	13,127,956	
Non-Agricultural	6,324,690	
		19,452,646
MOHAMMEDAN AND OTHERS,—		
Agricultural	1,596,277	
Non-Agricultural	2,150,745	
		3,747,022
Total Population of the North-Western Provinces		23,199,668

Number of Persons to each square Statute Mile	322·3
Number of Acres to each Person	1·99
Average Amount of Revenue per Head	1·742

In Madras the course adopted was altogether at variance with the feelings of the people, and the consequences were not more happy. In the Northern Circars, indeed, there was an ancient aristocracy, to whom the people looked up as their hereditary superiors, and through whom the supreme government could most conveniently realize its revenue. But in the other districts to which the permanent settlement was extended a novel and not very happy attempt was made to create an aristocracy by public auction. A cluster of villages called a mootah or zemindary was put up to sale, and the highest bidder became the new hereditary zemindar or mootahdar, the terms being synonymous. The government revenue had been previously assessed, not upon each field, nor upon each village, but upon the whole mootah or zemindary, and for this the new speculator in nobility was held accountable. There was under this system no bond of connection between the cultivators and the purchasers of the zemindary right, who were totally unconnected with the land; they were monied men desirous of elevating themselves by their wealth into the rank of rajahs. *Parvenus* are proverbially haughty and overbearing; and it is represented, and may readily be believed, that the ryots suffered considerable annoyance from these speculators. In consequence, however, of the provision made on their behalf, they frequently succeeded in vindicating their rights, and were generally in the course of time emancipated altogether from the dominion of the newly created zemindars, most of whom gradually failed, and with their families became involved in distress. The zemindars so completely mismanaged their zemindaries, that in the northern districts only one remained in a prosperous condition, their zemindaries having been for the most part transferred to the government officers as security for the payment of the revenue, and that they might be retrieved from the disorder into which they had fallen. In the Company's jaghire, in 1826, the zemindaries were reduced to 651 villages, paying a fixed jumma of 297,940 rupees; while lands had reverted to government to the extent of 1217 villages, paying a revenue of 488,960 rupees. In the Salem district a similar result followed. In the Dindigul district the zemindary settlement was introduced in 1804; but in 1807, the lands, with scarcely any exception, reverted to the government. That the permanent zemindary system is a bad one for the cultivator, there can be little doubt; that it is a bad one for the government, is equally clear. It has been suggested that under a zemindary system the rights of the ryots might be ascertained and protected. This, however, would be to combine two systems, instead of adopting one; and as one of the recommendations of the zemindary plan is its apparent simplicity and facility of application, such an appendage to it as the proposal implies can scarcely find favour in the eyes of those who regard it as an instrument for collecting the revenue with the smallest portion of trouble. But, if the rights of the ryots be admitted (and they are clearer than the rights of any other persons in India), on what principle can we justify the withdrawing from them the natural protection of government.

The observations of Sir Thomas Munro on the question are replete with sound vigorous sense. He says—"If, in place of lowering the assessment, and letting landed property rise in the natural way, we want to have great landlords raised at once where none exist, and for this purpose create zemindars, and turn over to each of them some hundreds of ryots, we should commit a gross injustice; because we should enable the zemindar in time to degrade the ryots from the rank of tenants-in-chief to that of tenants-at-will, and often to that of mere cultivators or labourers. We say that we leave the ryots free to act and to make their own terms with the zemindars or renters, and that if they were wronged the courts will protect them. We put them out of sight, deliver them over to a superior, and then we tell them that they are free to make their own terms, and that there are courts to secure their rights. But with what pretence of justice can we place them under any set of men to make terms for their property, and to defend it against them in courts of law? They have no superior but government; they are tenants-in-chief, and ought not to be obliged to make terms except with government. But it is said that the zemindar does not infringe their rights, because he has no authority to demand more than the dues of government as regulated by the usage of the country, and that if the parties be left to themselves things will find their proper level. They will find the level which they have found in Bengal and several districts under this government, and which the weak always find when they are left to contend with the strong. The question is, whether we are to continue the country in its natural state, occupied by a great body of independent ryots, and to enable them, by a lighter assessment, to rise gradually to the rank of landlords; or whether we are to place the country in an artificial state, by dividing it into villages or larger districts among a new class of landholders, who will inevitably, at no distant period, by the subdivision of their new property, fall to the level of ryots; while the ryots will, at the same time, have sunk from the rank of independent tenants-in-chief to that of sub-tenants and cultivators. It is, whether we are to raise the landholders we have, or to create a new set, and see them fall." The actual working of the system in Madras is described in another part of the minute from which the last quotation is made. "There is no analogy whatever between the landlord of England and his tenants, and the moohtadar or new village zemindar of this country and his ryots. In England the landlord is respected by the farmer as his superior; here a zemindar has no such respect, for the principal ryots of most villages regard him as not more than their equal, and often as their inferior. He is often the former potail or head ryot of the village; but he is frequently some petty shopkeeper, or merchant, or some adventurer or public servant out of employ. Whichever of these he is, he has usually very little property. He has none for the improvement of the village; but, on the contrary, looks to the village as the means of improving his own circumstances. The ryots, by being placed under him, sink from the rank of tenants of the government to that of tenants of an individual. They are transferred from a superior, who has no interest but in their protection and welfare, to one whose interest it is to enlarge his own property at the expense of theirs; who seeks, by every way, however unjustifiable, to get into his own hands all the best lands of the village, and whose situation affords him many facilities in depriving the ancient possessors of theirs. The ryots are jealous of a man whose new power and influence they have so much to fear. They frequently combine in order to keep down the cultivation, and force him, for their own security, to give up the village. And hence it has happened, that on the one side the opposition of the ryots, and on the other the oppression of the new zemindar, have in many instances caused villages which were flourishing and moderately assessed to revert to the circar from inability to pay their assessment." Never, indeed, were good intentions so lamentably frustrated as they have been by this system; and to attempt to make it universal throughout our Indian possessions, might shake the security of our empire. The system is radically vicious. Where, however, it already exists, we must tolerate it; but it would be a most fatal error, as all experience shows, to endeavour to extend it. Again, quoting the words of Sir Thomas Munro, when speaking of the effects produced by the forcible introduction of this system: "Such an innovation would be much more fatal to the old rights of property than conquest by a foreign enemy; for such a conquest, though it overthrew the government, would leave the people in their former condition; but this internal change, the village revolution, changes everything, and throws both influence and property into new hands. It deranges the order of society; it depresses one class of men for the sake of raising another; it weakens the respect and authority of ancient offices and institutions; and the local administration, conducted by their means, is rendered much more difficult. It is time that we should learn that neither the face of a country, its property, or its society, are things that can be suddenly improved by any contrivances of ours, though they may be greatly injured by what we mean for their good; that we should take every country as we find it, and not rashly attempt to regulate its landed property, either in its accumulation or division; that whether it be held by a great body of ryots, or by a few zemindars, or by a mixture of both, our business is not with its distribution, but with its protection; and that if, while we protect, we assess it moderately, and leave it to its natural course, it will in time flourish, and assume that form which is most suitable to the condition of the people."

The observations of the same distinguished person on the general principles which should guide those who undertake the high task of improving the condition of India, are no less just and instructive :—"We are now," he says, "masters of a very extensive empire, and we should endeavour to improve and secure it by a good internal administration. Our experience is too short to judge what rules are best calculated for the purpose. It is only within the last thirty years that we have begun to acquire any practical knowledge; a longer period must probably elapse before we can ascertain what is best. Such a period is as nothing in the existence of a people; but we act as if this were as limited as the life of an individual. We proceed in a country of which we know little or nothing as if we knew every thing, and as if every thing must be done now, and nothing could be done hereafter. We feel our ignorance of Indian revenue and the difficulties arising from it; and, instead of seeking to remedy it, by acquiring more knowledge, we endeavour to get rid of the difficulty by precipitately making permanent settlements, which relieve us from the troublesome task of minute or accurate investigation, and which are better adapted to perpetuate our ignorance than to protect the people. We must not be led away by fanciful theories, founded on European models, which will inevitably end in disappointment. We must not too hastily declare any rights permanent, lest we give to one class what belongs to another. We must proceed patiently, and as our knowledge of the manners and customs of the people and the nature and resources of the country increase, frame gradually, from the existing institutions, such a system as may advance the prosperity of the country, and be satisfactory to the people. The knowledge most necessary for this end is that of the landed property and its assessment; for the land is not only the great source of the public revenue, but on its fair and moderate assessment depend the comfort and happiness of the people." In another place Sir Thomas Munro adverts to the mistakes which have been committed in a manner which should operate as a warning against indiscreet zeal for the future :—"Our great error in this country, during a long course of years, has been too much precipitation in attempting to better the condition of the people, with hardly any knowledge of the means by which it was to be accomplished, and, indeed, without seeming to think that any other than good intentions were necessary. It is a dangerous system of government, in a country of which our knowledge is very imperfect, to be constantly urged by the desire of settling every thing permanently, to do every thing in a hurry, and, in consequence, wrong; and in our zeal for permanency, to put the remedy out of our reach. The ruling vice of our government is innovation; and its innovation has been so little guided by a knowledge of the people, that, though made after what was thought by us to be a mature discussion, it must appear to them as little better than mere caprice." Such observations, which would scarcely at any time be unseasonable, are peculiarly deserving of notice in an age, the ruling vice of which is that which Sir Thomas Munro ascribes to the English authority in India—innovation. The great error of concluding that laws and institutions which produce good effects in one country will therefore produce good effects in all other countries, must be carefully avoided; and if it be necessary to bear this in mind with regard to that which has been tried, though under different circumstances, the necessity is still more imperious with reference to systems altogether untried, and which have not the sanction of even a partial or local experience. If we would benefit the people of India, we must legislate for them as they are, and not as theorists conceive they ought to be. We must respect their local usages and institutions, wherever they are not productive of positive evil, and even where they are, they must be removed with a gentle hand. The general habit of the people is submission to authority, and it will be our own fault if they learn a different lesson. If we are content to derive a moderate revenue from the land, and to abstain from all interference with existing rights, except to protect them, the people will advance in wealth and happiness, and the British dominion take root in their interests and feelings. But if fanciful schemes, concocted in the closets of speculators and sciolists, framed with an ostentatious disregard of local peculiarities, claiming an universal applicability, and, like a patent medicine, "warranted to keep good in any climate," are imposed upon a people little addicted to novelty, in place of the institutions to which they have been accustomed—which have grown with the growth of the nation, and become part of its very essence—discontent, disgust, and confusion will be inevitable, and the final results may be such as no friend, either to India or England, can wish to contemplate. But while we discourage such a mischievous activity, we must not take refuge in indolence and supineness. It is at once our interest and our duty to settle nothing permanently till it can be settled in a manner satisfactory to the people; but it is also our interest and our duty to spare no labour that may be necessary to enable us to acquire that minute knowledge of Indian institutions which is indispensable to a satisfactory settlement. Of two plans we must not give the preference to one solely on the ground of its involving less trouble than the other. Nothing must be left to chance or accident, nor must the preservation of any class of rights be suffered to depend upon the clamorous violence with which they may happen to be urged. The weak as well as the strong, the silent as well as the loud, the ignorant as well as the informed, must be protected, and as we must not be parsimonious of labour, so neither must we be impatient of the consumption of time. The work to be accomplished is not that of a day or a year; and provided no time be wasted, it will, if well done, be done sufficiently early. The great principle to be observed in any mode of settlement is to offer as little violence as possible to the habits and feelings of the people. Wherever these do not stand in the way, wherever there is room for the exercise of a free choice, there can be no doubt at all that the ryot-war system is that which is best calculated to secure the cultivator from oppression, best calculated to promote industry, order, and independence, best calculated to advance the general prosperity of the country, and best calculated to protect the pecuniary interests of the government. That it is generally most consonant to the feelings of the people is certain. It is equally certain that the ryot-war system is the only one by which all individual rights can be protected, indeed, the only one by which they can be ascertained. And thus, unless a portion of the rights of the people, probably the most valuable rights of the most valuable class of the people, are to be regarded as unworthy of notice, a ryot-war settlement must be the basis of any other. The observations of Mr David Hill, formerly secretary to the government of Madras, upon this subject are much to the purpose; of course the settlement of which he speaks is such a one as it would become a just and upright government to make. He says, "You can no more form a zemindary settlement without a ryot-war one than you can write a correct hand without spelling, although in either case you may be unconscious of the subsidiary operation. The ryot-war settlement is an essential part of the zemindary one. If the officers of the government do not make settlements with the ryots, the zemindar must, and therefore the objections that are taken against a ryot-war settlement will not be obviated by the substitution of the other, except in as far as those objections apply to the ryot-war settlement being executed by the officers of government." The following account of the practical working of the plan will be acceptable to those who take an interest in the subject :—

"In the spring of each year, every native collector, of whom there are generally ten or twelve under the European officer in charge of a large province, makes the circuit of his district, to ascertain the fields which are occupied, and the individual holding the highest tenure in each. He then allows the poorer ryots to relinquish any fields they may not desire longer to retain, and grants these or other unoccupied or waste fields to such other ryots as desire to extend their cultivation.

"The settlement itself is not begun by the European collector until towards the harvest, when the native collector of each district, with his district accountant, is, in the first instance, summoned to meet him. The records of the district accountant show the result of the native collector's previous circuit through the villages of his district. The quantity of land in each village, with its assessment, is ascertained; that portion of it which the ryots have agreed to cultivate is distinguished from the rest, and the reduced field survey assessment on it, after the usual deductions in favour of those who have the revenue alienated to them, or remitted in their favour, forms the native collector's estimate of the probable settlement of the land revenue for the season. He then affords personal explanations as to the general state of the several villages in his district, and the local causes of those changes which are observable in the accounts compared with those of former years.

"This preliminary having been completed, the village accountants are next summoned to attend the European collector. Their more detailed accounts show how far the several ryots have completed the engagements into which they have entered with the native collector, and what fields of the land agreed to be cultivated have been left waste. The causes of these alterations are minutely investigated and explained, and the records of the village accountants are checked by information obtained from their competitors or other sources.

"The collector's native establishment then prepare from their data a separate account for every individual ryot, specifying the name of each field, whether irrigated, unirrigated, or garden-land, cultivated by him, or at his risk and charge, its number in the survey accounts, and its assessments, with the alienations or remissions (if any) in his favour. This account also exhibits the ryot's stock, the number of his cattle, sheep, &c.; that also of the persons of his family, male or female, the extent of land exempted from revenue cultivated by him, invariably on very easy terms; and his actual payments to the government for many years past. These, which are called the rough ryot-war accounts, form the basis of the European collector's final settlement; and when any discussion arises with a particular ryot, they enable the collector to decide the point at issue without delay, for they contain in fact a summary revenue history of each individual contributor.

"These accounts having been prepared for each ryot, the whole of the cultivators themselves in eight or ten villages, are ultimately summoned at the same time to the collector's presence. Here the account of each man, and the deductions (if any) made in his favour, are compared in detail with his own personal information by the collector's native establishment; any items in it to which objections are started are examined, discussed, and, if erroneous, corrected. It is here that the frauds of the village accountants are detected, by the envy, jealousy, or honesty of one ryot pointing out the favours improperly granted to his neighbour. The objections of the ryots, if ill-founded, are overruled by the explanations of the head of the village, the village accountant, or the other cultivators in the same village, or by the exhortations of the inhabitants of the neighbouring villages also present, for these persons never hesitate voluntarily to interfere, and to reprimand such as start unfounded objections; and a ryot who obstinately demurs for hours to the laboured and authoritative reasoning of the collector's native establishment, will often give way at once to the voluntary arguments of his fellows, whose explanations are, perhaps, better adapted to his capacity, and whose opinion being more disinterested, no doubt carries with it more weight. But if the ryot's objections are valid, he always persists in appealing to the collector himself. The details of every ryot-war settlement must devolve on the native servants. The presence of the European officer is no doubt useful to superintend the whole; but it is chiefly requisite, in order to afford on the spot, to every discontented ryot, this facility of instant access and immediate appeal, which affords the best check against either fraud or oppression in the course of the settlement. The collector, if a judicious revenue officer, seldom has occasion to decide such questions himself; he soon learns to distinguish amongst the ryots assembled which are those universally respected throughout the country for their good conduct, impartiality, and sound sense; and his call upon them for an opinion, invariably given publicly, without any previous preparation, whilst it silences all complaint, relieves the officer of the government from the odium of deciding questions in which its interests may often be involved.

"All discussions with the ryots having thus been terminated, the puttah or lease and its counterpart are drawn out, and the former having been sealed by the collector, the whole of the ryots in each village are called before him. Every man here separately exchanges engagements with the government, to the number of 60,000 or 70,000 in some provinces, and receives from the European collector's own hands his lease, accompanied by the betel-leaf, &c., the usual seal of all native compacts. If any ryot still objects to the terms of his lease, he declines to receive it, and the grounds of his objection are here formally discussed, and finally decided by the collector in open public audience.

"In each village its head or potail, the chief of the police, is also invariably the village collector on account of government. He realizes from each individual ryot the amount of government revenue as the instalments fall due, and remits it to the native collector of the district, also vested with magisterial powers similar to those of a justice of the peace, whence it is forwarded to the European collector, uniting in his person the superintendence of both the revenue and police departments over the entire province."

Such is the mode of proceeding adopted in those parts of the territories under the Madras presidency, subject to the ryot-war system, and it appears to possess many advantages.

In Bombay the revenue settlement is chiefly ryot-war. Under the new survey now in progress, the lands are subdivided into fields of moderate size, so that each subdivision is rendered easy of cultivation by a farmer of limited means. The government assessment is calculated separately upon each field, and leases granted for thirty years' duration at a fixed and invariable sum, binding on the government for the whole term, but with the option on the part of the cultivator of surrendering any one or more of his fields, or altogether putting an end to his lease at the close of any given year.

The great source from which the financial wants of the state are supplied is the land revenue. The other chief sources of Indian revenue are the monopolies of salt and opium, the customs duties, the duties included under the term abkarree, comprising those on spirituous liquors, intoxicating drugs, and some other articles; the post-office receipts, and the mint and stamp duties. Of these various modes of taxation, the monopoly of salt is the only one against which any reasonable objection can be raised. It exists in Madras, in the north-western provinces, and in the lower provinces of Bengal. In the last mentioned provinces the East India Company make advances to a description of persons called Molunghees, who are the manufacturers, and the salt is disposed of by auction at monthly sales. In Madras the salt is sold at a fixed price, which does not exceed one-fourth of the average price in Bengal; but it is said that the profit derived from it is considerable, the cost of production being comparatively small. Various objections have been taken to this source of revenue; and one of them is certainly not undeserving of consideration. It cannot be denied that a regulation which, for the mere purpose of revenue, adds enormously to the price of an article which must be regarded as a prime necessary of life, is an evil of no small magnitude. But those who urge this are bound to show how the same amount of revenue could be raised less injuriously. It is quite clear that it must be raised by some means. The wants of the state must be provided for, and an annual deficiency of upwards of a million and a half sterling, which would result from the abolition of the salt monopoly, could not be supplied with any degree of certainty from new sources. Upon this ground the Company have been permitted, notwithstanding the extinction of their commercial character, to retain this branch of trade. Some modification in the mode of realizing the salt revenue is however about to take place. The monopoly of manufacture has been denounced in the House of Commons, and it has been resolved to try the experiment of permitting the manufacture by private individuals under a system of excise. In Bengal the revenue from opium is realized by means of a government monopoly. No person within the Bengal territories is allowed to grow the poppy, except on account of the government. Annual engagements are entered into by the cultivators under a system of pecuniary advances, to sow a certain quantity of land with the poppy, and the whole produce in the form of opium is delivered to the government at a fixed rate. The engagements on the part of the cultivators are optional. A large revenue is derived from the transit of the opium of Malwa through the British territories of Bombay for exportation to China. Previous to the year 1831, the British government reserved to itself a monopoly of the drug which was purchased by the British resident at Indore, and sold by auction either at Bombay or at Calcutta. But in that year it was deemed advisable to relinquish the monopoly in Central India, to open the trade to the operations of private enterprise, and to substitute, as a source of revenue in place of the abandoned system, the grant at a specified rate of passes, to cover the transit of opium through the Company's territories to the port of Bombay. The following table contains the latest account of Indian revenue and taxation:—

Excise	L.28,614	
Land revenue	15,391,666	
Sayer, &c.	1,157,214	
Moturpha	119,257	
		L.16,696,751
Mint duties		129,079
Stamp duties		487,955
Customs		1,684,763
Salt		2,099,959
Opium		4,259,778
Tobacco		89,677
Miscellaneous		2,384,275
Total		L.27,832,237

The commercial monopoly of the East India Company was granted by William III. in the year 1698, and it was confirmed by 9th and 10th William III. c. 44. The legislative enactments regarding the territorial possessions of the Company commenced in 1767. In that year it was agreed that, in consideration of an annual payment of L.400,000, the territorial possessions should remain in possession of the Company for two years, and afterwards for five years from the 1st of February 1769. There was paid to the public, under these two acts, from 1768 to 1775, the sum of L.2,169,398. In 1773 the affairs of the Company were much embarrassed, and they presented a petition to parliament soliciting a loan for four years, and a sum of L.1,400,000 was accordingly lent; and at this time parliament first assumed the regulation of the Company's affairs. The dividend was restricted to 6 per cent. till this loan should be repaid, and afterwards to 7 per cent. It was enacted that the directors should be elected for four years, six of them, being a fourth part, to vacate their office annually by rotation; the qualification to vote in the court of proprietors to be raised from L.500 to L.1000. A new court of judicature was at the same time established at Calcutta, consisting of a chief justice and three principal judges, appointed by the crown; and a superiority was given to Bengal over the other presidencies; an appropriation was made of the revenues and profits of the Company, and they were required to make half-yearly statements of their debts, and of the profit and loss incurred on their trade and revenues. The loan of L.1,400,000 having been discharged, two other acts were passed, by which the territory was continued to the Company for one year. In 1781 an act was passed continuing the territoral revenues and privileges of the Company till the 1st of March 1791, and then to be taken away only on a three years' notice; providing also that the Company should pay annually L.400,000 to the public, besides three-fourths of any surplus revenue that might accrue.[1] Under this act the Company paid to the public L.400,000 in satisfaction of all claims up to the 1st March 1781. But of the annual sum of L.400,000, which was afterwards to be paid, the public received only L.300,000; and in 1783 the Company were allowed to borrow L.800,000, and out of this borrowed money to pay a dividend of 8 per cent. By the act of 33d Geo. III. c. 52, passed in 1793, the British territories in India, together with the exclusive trade, were continued to the Company for twenty years; and the Company agreed to pay L.500,000 annually, unless prevented by war expenditure. But only two payments were made, of L.250,000 each, under this act, in 1793 and 1794. In 1814 the charter of the Company was renewed for twenty years; the trade to India opened under certain limitations, with the exception of the trade to China, the monopoly of which, with all the territorial revenues, was continued till 20th of April 1834. In 1833 a new act was brought forward by Mr Grant, for the future administration of the vast dominions of the Company, and for the general regulation of their affairs. By this act the commercial privileges of the East India Company were abolished, and the trade to India and to China was thrown open to all British subjects. The government of India was still vested in the directors of the Company, in conjunction with the board of control, according to the provisions of Mr Pitt's bill. All natural born British subjects were permitted to reside without license in any part of the territories which were under the government of the Company on the 1st day of January 1800, in any part of the countries ceded by the nabob of the Carnatic, of the province of Cuttack, and of the settlements of Singapore and Malacca. The only conditions required are,—that the party shall proceed by sea, and shall on arrival give notice of his name, place of destination, and objects of pursuit. A license is still necessary in the territories not specially excepted by the act. A British subject may hold lands in any place where he is authorized to reside. The reform of judicial proceedings, and the compilation of a uniform code of laws for Hindus and Mohammedans as well as European subjects, a great and important undertaking, forms part of this comprehensive and enlightened plan for the government of India. In 1833, in consequence of the great extension of British territory, it was enacted by parliament that the presidency of Bengal should be divided, and a portion of it formed into a new presidency, to be styled the presidency of Agra. But a later act of parliament authorized the East India Company to suspend the execution of the contemplated division, and provided that during such suspension the governor-general in council might appoint a servant of the Company of ten years' residence to be lieutenant-governor of the north-western provinces under such limitations as may be prescribed. Under that act the establishment of a new presidency was accordingly suspended, and a lieutenant-governor of the north-western provinces appointed. By a later act

Mr Grant's act.

---

[1] On this clause Colonel Munro justly observes, "This is converting India into a rack-rent estate for England."

the suspension is to remain until the court of directors shall otherwise determine, and in the meantime the provisions for the appointment of a lieutenant-governor of the north-western provinces, and the arrangements consequent thereon, are to be in force. Under the sanction of the same act a lieutenant-governor has been likewise appointed over the lower provinces of Bengal; and the East India Company are further empowered to erect another new presidency, and, pending its formation, they may authorize the establishment of an additional lieutenant-governorship. This privilege has not yet been exercised.

The objects of the Company were originally purely commercial; and could they have pursued them in peace and security they would have sought nothing further. Their enemies compelled them to unite with the character of the merchant that of the soldier and the civil governor. The British legislature has effected a change scarcely less unexpected. In 1813 the trade with India was thrown open; twenty years afterwards the Company relinquished the field to their competitors. The history of the world affords nothing more extraordinary than the present posture of the Company. Formed exclusively for the prosecution of a desirable branch of commerce, it has renounced trade, yet continues to exist for purposes which its founders never contemplated. Called incidentally to the exercise of civil and military power, it continues to wield that power now that its original character has disappeared, and when it has no longer any interest in those commercial advantages which it was the single purpose of its conquests to secure. The act of 1833 suspended the mercantile career of the Company, and it now exists only as an instrument for governing the country, which the wisdom and spirit of its servants has annexed to the British crown. The whole of the Company's property, territorial and commercial, having been surrendered, its debts and liabilities are charged upon India, and a dividend of L.10, 10s. per cent. on their capital stock secured; the dividend redeemable at the rate of L.200 for every L.100 stock after April 1874, and at an earlier period on the demand of the Company, should they be deprived of the government of India. For the better securing the redemption of the dividend, a fund is formed, under the control of the commissioners for the reduction of the national debt, termed the Security Fund of the India Company. For the purposes of this fund a sum of L.2,000,000 has been invested in the public funds, there to accumulate to the amount of L.12,000,000.

It will now be proper to advert to the present constitution of the Company and the Government of India as settled by the last and preceding acts of parliament. The authority of the Company is exercised through the court of proprietors and the court of directors. To be qualified to vote in the former court, a proprietor must have been twelve months in possession of stock to the amount of at least L.1000; this sum entitles him to one vote, L.3000 to two votes, L.6000 to three votes, and L.10,000 to four votes. The proprietors have the privilege of electing a specified number of the directors; of making bye-laws for the regulation of the Company, which are binding when not at variance with the law of the land, and of controlling all grants of money exceeding L.600. The directors are bound to convene a general court on the requisition of nine qualified proprietors; and such court, while it may discuss any matter connected with the affairs of India, has no power of rescinding a measure adopted by the directors, and approved by the board of control. In the election of directors a proprietor may vote by attorney. The constitution of the court of directors has been subjected to considerable modification by the provisions of an act of parliament passed in 1853. By the charter of William III., there were to be twenty-four directors, thirteen or more to constitute a court for the transaction of business; such directors to be elected annually by the members of the Company, and each director to be possessed of at least L.2000 stock. By the act known as the regulating act, 13th Geo. III., cap. 63, some alterations as to the qualifications of voters were made; the number of twenty-four directors was retained, but instead of the whole being elected annually, six only were to be chosen in each year to serve for four years, at the expiration of which term the retiring six were to be incapable of re-election until the lapse of one year. This state of the law continued until the act passed in 1853 came into operation. By that act it will be seen that the number of directors is reduced from twenty-four to eighteen; that of these, three in the first instance, and eventually six, are to be nominated by the Crown; that ten directors are sufficient to form a court; that the signatures of three specified members of the court, or of two of them duly countersigned, are to have the effect of the signatures of the majority previously required by a bye-law of the Company; that the term of service for each director, whether elected by the proprietors or appointed by the Crown, will, when the act shall come fully into operation, be six years; that directors having completed this term are to be immediately eligible for re-election or re-appointment; that all directors appointed by the Crown must have resided ten years in India in the service either of the Crown or of the Company, and that six of those to be elected by the proprietors must also have resided in India ten years, no such condition having previously been required; that the stock qualification for a director is reduced from L.2000 to L.1000; that elections are to be biennial instead of annual, and that a new oath is substituted for those formerly administered to the directors. The chairman and deputy-chairman receive each a salary of L.1000, and every other director L.500 per annum. The military patronage of India is still vested in the court, but the right of making appointments to the civil service has been withdrawn from the directors, and writerships for India are now thrown open to public competition, as are also the appointments to the medical service of the Company. At the first examination under the new system of parties offering themselves as assistant-surgeons, Mr Chuckerbutty, a native of Bengal, came forward as a candidate and succeeded in carrying off an appointment. The successful candidates for civil appointments will not be required to finish their education at Haileybury; and the institution known as the Haileybury College is about to be abolished.

The East India Company consists, according to the latest calculation, of 1750 proprietors, who are privileged to meet in a general court and vote. A proprietor of the Company's stock, provided it has been in his possession for twelve months, to the amount of L.1000, has one vote; of L.3000, two; of L.6000, three; and of L.10,000, four votes; several proprietors hold stock under L.1000, and are not qualified to vote. The total number of votes is estimated at 2600. The proprietors meet every quarter. Their powers are limited to the election of directors, to the framing of bye-laws, and to the control of salaries or pensions exceeding L.200 a-year, or gratuities exceeding L.600. In the court of directors and the board of control is vested the sovereignty of India; they regulate by their supreme authority the policy of the resident government, and the court of proprietors has no power to interfere with their orders.

Presidencies.

India is divided into the three presidencies of Bengal, Madras, and Bombay. The governor-general is governor of the presidency of Bengal, which, in addition to several large provinces and extensive tracts of territory, includes within its limits, as already noticed, the two lieutenant-governorships of Bengal, and the N.W. provinces. The governor-general is appointed by the court of directors, subject to the pleasure of the Crown. His council, nominated by the court, subject to the approbation of her Majesty, consists of four members, three of them being servants of the

Company of ten years' standing. The fourth member of council is not to be chosen from the servants of the Company, but his appointment also is dependent on the approbation of the Crown. The act of parliament passed in 1853 provided for the addition of several legislative councillors to the council of India, but these are not entitled to sit or vote except at meetings for making laws and regulations. They consist of one civil servant for each of the presidencies, and for each lieutenant-governorship, and of two of the judges of the supreme court of judicature at Calcutta. The court of directors may also appoint the commander-in-chief of the forces in India, an extraordinary member of council. The governor-general in council is supreme in India, but all laws and regulations disallowed by the court of directors, under the control of the board, are to be forthwith repealed, and no law is to be made without their previous sanction, which shall give to any courts of justice, except those established by royal charter, the power of punishing her Majesty's European subjects with death, or which shall abolish any of the courts established by charter. The presence of the governor-general or vice-president, or some ordinary member of council, and six other members, is necessary to give validity to any act of legislation. The other functions of government may be exercised by the governor-general and one member. If the voices are equal, the governor-general has a second vote; and in cases where he may consider the peace and safety of the country materially affected, he may, after certain forms, act on his own responsibility in opposition to the opinion of the majority of the council. The administration of the affairs of each of the subordinate presidencies of Madras and Bombay is committed to a governor and three councillors. The governor-general is governor of the presidency of Fort-William, in Bengal, and has the power of appointing a deputy-governor in case of necessity; but it is competent to the court of directors to supersede these provisions whenever they shall think fit, and to appoint a separate governor for the presidency of Bengal. The appointments to the subordinate presidencies are subject to the same regulations as that of the governor-general and his council. If the court of directors do not supply vacancies within two months' notice of them, the crown may appoint. The Queen may also remove any person holding office under the Company. The same power of removal is possessed by the court, with the exception of officers appointed by the Crown. And the court, under the control of the board, have the further power of reducing the number of councillors in any of the presidencies, or of suspending the appointment of councils altogether.

Indian army.

Each presidency has its separate army, commander-in-chief, and military establishment. But the commander-in-chief of the Queen's and Company's forces in India has a general authority over the military force in the other presidencies. The total armed force in British India is about 290,000. This force consists—1*st*, of the Queen's infantry and cavalry; 2*d*, of the East India Company's European engineers, artillery, and infantry; and, 3*d*, of the Company's native artillery, cavalry, and infantry. The European troops in India—Queen's, and Company's—amount, according to the latest accounts, to 49,400; the native troops to 240,120, highly distinguished by their valour, good conduct, and discipline. The complement of European officers to each infantry regiment is, one colonel, one lieutenant-colonel, one major, six captains, ten lieutenants, and five cornets or ensigns. Of native officers there is a subahdar and jemadar to each company. The expense of the Anglo-Indian army at the three presidencies of Bengal, Madras, and Bombay, in 1854, was respectively L.5,278,642, L.2,666,069, and L.1,589,846, giving a total of L.9,534,557. The Indian navy consists of six frigates and eleven armed steamers. The British ecclesiastical establishment consists of three bishops, and 129 European chaplains, the Bishop of Calcutta being the metropolitan bishop in India. There are also Scottish Presbyterian churches at Calcutta, Madras, and Bombay; two chaplains of the Church of Scotland being maintained by the government at each presidency.

The British entered India as traders. They were compelled to exchange the operations of commerce for the labours of war. Success attended their military career, and renewed provocations urged them to continue it. Victory has followed victory, and conquest been accumulated upon conquest, until the dominion of Britain embraces the larger portion of India, and its influence extends over the whole. To look back upon the achievements of our countrymen cannot but be gratifying to our national sympathies; to look forward to the probable fate of that empire which their skill and courage raised from such small beginnings, is a duty which is imposed upon us by a regard to our national honour, as well as to the integrity of the British dominions. The stability and permanency of our power may be endangered either from within or from without. Our first attention must naturally be directed to our own subjects. From their hostility, if provoked, our greatest danger would arise; on their attachment, if secured, our safety may be firmly based. To acquire the confidence of the people over whom we rule, and, having acquired, to preserve it, must be the grand objects of our policy. In those parts which have been longest subjected to our rule, our power is most firmly established. The people and the government have become more habituated to each other, and our authority is more cheerfully recognized from a perception of the benefits which it has conferred. For some years past natives of India have been appointed to offices of high trust and emolument. Civil justice, indeed, is now almost wholly dispensed by native judges. This enlightened policy was confirmed by the British parliament in 1833, and again in 1853; and the free admission of the natives, of whatever religion or caste, to all offices, and of British settlers into any part of India, there to acquire property or land, or to carry on any trade or profession, is calculated to promote the lasting advantage of India, establishing, as it does, the principles of freedom, not upon the mere arbitrary regulation of the supreme council, which may be recalled, but on the solid authority of a British act of parliament, which no inferior power can disannul.

Under this liberal and comprehensive law—the Magna Charta of Indian freedom—the British merchant may transfer his capital, and his superior intelligence and industry, to the most remote parts of Hindustan; he may engage in trade, in manufactures, or in agriculture; and this free intercourse of India with Britain must in time produce important effects on the character and manners of the people. Hindustan appears, indeed, to be on the eve of a great moral revolution. The spirit of improvement has long slumbered amongst that singular people; and the division of the people into castes, and those superstitions to which they are attached with a blind devotion, are unfavourable to its progress. But the influence of European manners now begins to be seen; and, considering that the Hindus are a conquered people, long bowed under a foreign yoke, that, on the other hand, power, dominion, honour, and promotion belong to the British, it is no wonder that the prostrate and servile Hindu should be induced gradually to forsake the manners and superstitions, and even the language of his forefathers, for the enlightened views and purer faith of his victorious preceptors. This great and signal revolution is already begun. The manners, the customs, the language of Britain are beginning to take root in India. They have been adopted by many natives of distinction, by zemindars, as well as by the rajahs and princes of the country; and from their example they are spreading amongst the other classes. Hindu children of both sexes crowd the British seminaries established at Calcutta; the rising generation resort to the colleges, and are instructed in English literature and science; they frequent the medical and surgical schools; and there is a growing disposition to adopt the free and liberal manners, and all the other improvements of modern Europe. This moral change, which is already begun, will soon, by the free influx of Europeans, reach the remotest parts of Hindustan. Capital will be introduced, agriculture will be promoted, and improved modes of labour will be adopted. And all these changes will be brought about, not by any violent subversion of existing institutions, but gradually, through the quiet influence of moral causes.

Amongst other sources of improvement in Hindustan, may be reckoned the laudable zeal of the government for the instruction of the people, by the institution of colleges and schools throughout the country, in which are taught all the different branches of literature and science. It was stipulated by the charter in 1814, that a sum of L.10,000 should be annually applied to the purposes of education; which sum has been augmented, by the liberality of the government, to L.80,000 in 1853. Previous to the year 1821 the only native educational establishments founded in India by the British government were the Mohammedan College at Calcutta, and the Sanscrit College at Benares, established respectively in 1781 and 1792. The Hindu College of Calcutta, though founded in 1816, was not subjected to government superintendence until 1823. In 1835 the number of seminaries had increased to fourteen, while, in 1853, in the upper and lower provinces of Bengal alone there were upwards of forty. In the earlier founded colleges the studies were purely Oriental; in those subsequently established they are European. The preservation of native learning was the avowed object in the one case; the communication of useful knowledge, and the affording facilities for the study of elegant literature were the ends sought in the other. The instruction of the masses in this knowledge was the ultimate end to be attained; but much valuable time was unfortunately lost, pending the result of the experiment resorted to in the first instance of translating English literature into Arabic and Sanscrit, the classical languages of the East. Under this arrangement, before a native student could become versed in European knowledge, it was indispensable that he should first become an accomplished Oriental scholar. The scheme was unsuccessful. But upon the termination of the East India Company's charter in 1834 the subject again came under consideration; and on the 7th March 1835 the government of India passed a resolution substituting the English for the Oriental scheme of education. The new plan offers to the native student a complete education in European literature, philosophy, and science, through the medium of the English language; it introduces him to the entire range of science and literature, so far as he is able to receive it, the limit being that alone fixed by nature in regard to his own capacity. English is now the classical language of India. Colleges and schools have been established in the principal cities and towns, and the old Mohammedan and Hindu institutions, though upheld as seminaries of Oriental learning, have had English classes attached to them. Stipends formerly paid to pupils without reference to ability, diligence, or acquirements, have been abolished, and in lieu thereof, scholarships have been founded, which can be gained only by passing a satisfactory examination. Junior scholarships are also attached to the new schools, tenable at the central college to which the school is subordinate, and where a higher course of instruction is available. Another important step in the advance of national education has just been taken, and grants in aid are now bestowed, both upon native and missionary schools, in furtherance of secular instruction—the religious tuition of the scholars being left to the discretion of the masters and proprietors of the schools. And with these institutions for the education of the people is now combined that mighty engine the press, which, though opposed in its first efforts, and rigorously persecuted, has in India, as in all other countries, finally broken down all the restraints of despotism, and achieved its own freedom. To these sources of improvement may be added the missionary labours, which are ardently pursued all over India, in the establishment of schools, in the sending out of preachers, and in the printing and dispersing of the sacred volume and other works in the native languages, on which large sums of money have been expended. Such are the various institutions which are in progress for the civilization of Hindustan, and which are destined ere long to produce important results, not only in that country, but throughout the whole extent of Asia. But those great moral changes which affect the condition of society are in their nature slow and gradual; they cannot be hastened forward, more especially amongst such a people as the Hindus, whose minds are enthralled by the force of their peculiar habits and religion, by immemorial usages, and by the deep-rooted prejudices of ignorance. We cannot expect that long-established habits will be suddenly relinquished, or that fixed impressions will at once yield to the voice of truth. But Great Britain has at last, and in earnest, undertaken the task of instructing her Indian subjects. The foundation is laid; the work of improvement is begun; the seeds of knowledge have been widely dispersed over the congenial soil, and they will assuredly spring up, and in due season yield the desired increase.

But while the arts of peace are treated with favour, we must be prepared for the opposite state if it should become necessary. Looking to this contingency the Indian army becomes an object of vast importance. Our dominions are not assailable from without only. Within their circle are portions of territory under the rule of native powers, nominally allies indeed, but for the most part to be regarded as hollow friends. The formidable alliance formed some years since to drive us from India shows the feelings with which we are regarded by the old Mohammedan authorities; and though their power is now broken and destroyed, we must not imagine that their hostile feeling towards us is abated. We must therefore at all times be prepared to defend ourselves. The knowledge that we are so prepared will be the best security for our safety and the general peace. From without we have little to fear. The frontier of our dominions is singularly unassailable, considering the extent of territory—the country, of which a part is subjected to our direct rule, and the whole to our influence, being in a great degree secured by nature from external attack. The sea rolls around a large portion of it; mountains affording few passes; and desert countries scarcely passable at all, bound the rest. Russia has been regarded with some apprehension, and she may possibly have been well disposed to add India to her vast empire; but her energies and capacity for intrigue have been hitherto directed to a quarter more dear to her ambition than India. The grand object to which Russia has ever appeared willing to sacrifice every other is the incorporation of Turkey with her dominions. But in her recent attempt to accomplish her purpose she has been signally foiled, and as her resources have been severely crippled by the struggle, a considerable period must doubtless elapse before Russia can be in a condition to turn her eyes farther eastward. In the meantime it is gratifying to know that the British empire in India is in such a state of security as must disarm every fear, and leave its rulers at perfect liberty to devote an undivided attention to the advancement of the happiness of the people. (E. T.)

HINGE, an iron or brass joint, on which doors, lids, gates, and shutters swing, fold, open, or shut up. The common form of a hinge is two leaves, perforated with holes for screws, and furnished each with projecting segments of a hollow cylinder, which fit into each other, and are secured by means of a central pin. This joint is applied by screwing one leaf to the door and the other to the doorpost. Hinges for gates and out-house doors are made in the form of the letter T; they are called *cross-garnets.* They are sometimes made with long straps and hooks to fix in the stiles, so that the gate or door may be lifted off its hinges when required. Hinges for the doors of rooms are called *butts*, and are of various kinds. Hinges for shutters are termed *back-flaps.* Similar kinds are used for the joints of bedsteads, and for Pembroke and other tables. **H** and **H–** hinges, so called from their form, are in common use. Improved forms of hinges have been made the subjects of numerous patents. Collinge's hinge, improved by Redmund, has its bearing pin in the form of a conical stem, with a sharper conical top corresponding with the bearing socket, and over this is a hollow cap containing oil, which enables the two surfaces to work with great truth and freedom. Redmund's hinges or *rising-butts* have the hollow cylinder which is attached to the leaves divided, not at right angles to the pin, as is usual, but by spiral or helical lines, so that on opening the door it is lifted from the floor by the rubbing surfaces of the hinge moving upwards in a helical line, so that when the door is left to itself, its weight causes it to descend by the inclined rubbing surfaces, and thus to close itself. The door can, however, be made to stand wide open by cutting away a portion of the helical curves so as to form two horizontal planes, which become opposed to each other when the door is opened sufficiently to form a right angle with its position when shut. Hence the door will close of itself, when it is not pushed open more than 50° or 60°; but it will stand wide open if pushed to 90°. Spring-hinges for the swing-doors of public offices, &c., made to open either way, and to return quickly to their shut-to position, are numerous. In Whitechurch's hinge, doors, windows, &c., can be opened either to the right or left hand. Nettlefold's hinge for book-cases allows the door to fold back quite level with the book-shelves, so that books close to the hinge can be taken out and put in with facility. There are also numerous patents for casting iron and brass hinges, as well as for stamping the same. (C. T.)

HINNOM, or rather BEN-HIMMON, an unknown person, who seems to have given his name to the valley which bounds Jerusalem on the N., below Mount Zion. (See GEHENNA.)

HINOJOSA DEL DUGUE, a secular town of Spain, in the province of Estremadura, and bishopric of Cordova. It contains a parish church, a monastery, a convent, and two hospitals. It is situated in a level district surrounded with hills; and its boundaries are washed by the Rivers Zujar and Guamatilla. The climate and the water are excellent. Pop. 7748.

HIPPARCHUS and HIPPIAS, the sons of Pisistratus, succeeded their father in the *tyrannis* of Athens. Strictly speaking the right of government belonged to Hippias, who, on the express testimony of Thucydides (which, however, is at variance with that of other historians), was the elder of the two, but the brothers seem to have administered public affairs conjointly with an extraordinary unity of purpose. They carried out the principles of their father, and the period of their sway, at least till the murder of Hipparchus, B.C. 514 (see HARMODIUS), was looked upon by the people of Athens as a sort of golden age. After his brother's death Hippias' character underwent a total change. He became a "tyrannus" of the worst type, and ruled with such intolerable severity that he was at last obliged to fly from Attica to escape the fury of the many enemies he had raised about him. After various wanderings, he took refuge in the court of Darius, king of Persia, and instigated that monarch to the invasion of his native country. He joined the expedition sent out under Datis and Artaphernes, and accompanied it to the field of Marathon, after which all trace of him in history is lost.

HIPPARCHUS, the most celebrated of all the ancient astronomers, was a native of Nicæa in Bithynia, and flourished in the second century B.C. His history and works are very fully discussed in the historical part of the art. ASTRONOMY.

HIPPOCRATES, the "Father of Medicine," was born in the Island of Cos, B.C. 460. By his father Heraclides, he was descended from Æsculapius, and by his mother Phænarete, from Hercules. After the preliminary instruction received from his father, he proceeded to Athens to prosecute medicine under Herodicus. He studied philosophy under Georgias, and some add Democritus of Abdera. He travelled in Thessaly, Macedonia, and Scythia, latterly settling down in the first of these places. Here he died at Larissa about B.C. 357, at the age of about 100.

A parallel has been drawn between Homer, the father of verse, and Hippocrates, the father of medicine. Each remounts to great antiquity, and each is first in order of excellence. Yet so little is known about either, that the history of each has become clogged with numerous accretions of mere fable; while, passing to the opposite extreme, some have doubted whether the men themselves ever existed at all. Some of the stories circulated about Hippocrates may be mentioned. He is represented as having the charge of a library at Cos or Cnidos. Having used the works of others much too freely in his writings, and fearing detection, he is said to have set the library on fire. But the uniform respect, even veneration, with which he was regarded in his own day appears satisfactorily to contradict such a story. Plato, his contemporary, speaks of him in very high terms; and as to the conflagration, Pliny speaks of the destruction by fire of votive tablets, without reference to books or Hippocrates. The story appears to have been invented three centuries after Hipprocrates by one Andreas. A similar story is told of Avicenna. Another story represents Hippocrates as sent for during the illness of the son of Perdiccas II. of Macedonia, and as discovering, by mere appearances, that the malady was caused by the young man's being in love with Philas, his father's concubine. A similar tale is told of Erasistratus at the court of Seleucus Nicanor. According to a third story the portrait of Hippocrates was taken, by some of his disciples, to a physiognomist. It was declared by him to be that of an old man of lascivious character. His disciples laughed at the conclusion as utterly incorrect; but Hippocrates declared that the physiognomist had rightly discerned his natural character, which, however, had been subdued by him. A similar story is told of Socrates. He is described as receiving extraordinary honours from the Athenians, and this connects him with another story, which relates to his removing a plague by keeping up large fires in the streets, and burning aromatic substances. By this means the atmosphere was purified. It is argued that this cannot refer to the celebrated plague by which Athens was devastated, else Thucydides, in describing it, would have made reference to Hippocrates. The other story is that which refers to the mission of Hystanus, the Persian satrap, from Artaxerxes Longimanus, to request Hippocrates to come to the Persian court, and give the king the benefit of his medical skill. Hippocrates replied that he would not accept of any presents to go and help the enemies of Greece.

Hippocrates created a new era in medicine. Up to his time medical knowledge was mainly monopolized by the priests, who kept to themselves as much as they did know. Emancipated from the jugglery of the priests, the study of medicine became henceforth an independent profession. Hippocrates theorized but little, his leading principles being the result of extensive observation of facts. The infirmities to which men as nations or individuals were subject, he traced to two leading causes—climate and diet. Hence he inculcates the importance of considering the changes of the seasons, the state of the atmosphere, the distribution of heat, water, moisture, &c. Diet is to be regulated, not only by the state of the patient, but also by the season of the year. Thus wine is to be used more sparingly in summer than in winter. In cases of fever, diet is to be reduced to liquid, though not so as to starve the patient. Each period of the year, according to him, has its peculiar malady. Hippocrates excells especially in describing the symptoms of diseases. His description of the sharp nose, sunken eyes, leaden hue, and dry forehead, which often precedes death, has been called the *Facies Hippocratica.* He gives minute directions for the discovery of empyema in the chest, notices the changes which take place in ulcers before death, and points out how symptoms may be ascertained from the manner in which the patient lies in bed.

In his treatise on the *Nature of Man* he enounces the theory of elements. As there are the four elements—fire, air, earth, and water; so there are in the human composition the four humours—blood, phlegm, bile, and black bile. When these are mixed in certain proportions the human body enjoys health; but disease is the result of a want of the proper proportion. He was the first to assign three periods to the course of a malady, and for the last, or the crisis, he assigned certain days, known as the *critical days.* These were the 4th, 7th, 11th, 14th, 17th, and 20th, displaying a regularity which may have existed more in his day and in his country than among us, owing partly to climate and partly to the simple habits of the people.

His knowledge of anatomy was very defective. He speaks of the muscles simply as flesh; he confounds the veins and arteries, also the nerves, tendons, and ligaments. As to generation, he believed that the male child came from the right side of the matrix, and the female child from the left. However, he came to some correct conclusions regarding the cranium and the viscera. It is possible that this may have been the result of examinations in the case of severe accidents to patients. The dissection of the human subject, in those days, appears to have been avoided from superstitious motives. Hippocrates did not advance so far as to separate surgery from medicine. He employed the cautery in some cases, as appears from his maxim—that what cannot be cured by medicine must be cured by the knife; and what cannot be cured by the knife must be cured by fire.

He practised bleeding, and in cases of inflammation he recommended the bleeding to take place near the inflamed part. He was acquainted with cupping also. He knew the medicinal properties of several minerals and vegetables, and used to employ violent purgatives. He is known to have practised auscultation. He was not aware of the importance of the pulse in detecting symptoms. He recommended consultations of physicians.

The candour and openness of Hippocrates stand out in noble relief from the secrecy and trickery of the priests, from whose monopoly he wrested the profession of medicine. On several occasions he mentions the mistakes into which, in his earlier practice, he had fallen, that others might have the benefit of his warning. More lofty and humane views than those which occur in his writings regarding the work of a physician are nowhere else to be met with:—"Be not too eager merely to get wealth by your profession. Give medical aid at times gratuitously, satisfied with the gratitude and esteem of others. Give assistance, as occasion presents itself, to the poor and the stranger; for if you love mankind you will love your profession. When you are required at a consultation, do not use great words, and do not speak in a studied and pompous manner—nothing more surely indicates incapacity." In the "oath" the physician is represented as solemnly promising, "My sole object shall be to afford consolation and medical relief to the sick, to be true to the confidence which they repose in me, and to avoid even the suspicion of having abused it, particularly in regard to women." He appears to have been very conscientious in the discharge of his professional duties. It has been objected that, by merely observing the course of nature, and trusting too much to her *vis medicatrix,* Hippocrates allowed his patients to die; and there appears to be some truth in the allegation.

Hippocrates wrote in the Ionic dialect, but numerous Atticisms occur in his works. What is known as the *Hippocratic Collection* is a great number of works, amounting to about 70, of which only a few are certainly known to be from the Hippocrates of whom we are speaking. The works to be ascribed to him are the *Aphorisms, Prognostics, Epidemics,* the treatise on *Air, Water,* and *Locality,* the treatise on the *Diet* to be used in acute diseases, &c. Of the others, some are probably by him, others possibly by him, and many certainly not by him. This confusion has been ascribed to two causes:—First, There were many medical writers not only of the same name, but also of the same family of Hippocrates. Thus the family of Hippocrates contained not fewer than seven physicians of greater or less eminence, spreading over a period of about 300 years. The tendency in such a case is to ascribe to the most distinguished the works of those less distinguished. But, secondly, when the Ptolemæan kings were founding the celebrated Alexandrian library, which was to surpass that of the kings of Pergamos, the works of Hippocrates were eagerly sought, and purchased at a high price. The consequence was that there was an inducement to the dishonest to palm off upon the Alexandrians books under the name of Hippocrates which were not his. Several of the works falsely ascribed to him can be at once set aside by the pomposity of style so totally different from the brevity of Hippocrates, bordering, as it often does, on obscurity. In cases of mutilation and interpolation, where an attempt has been made to imitate the Hippocratic conciseness, the critic has to look for statements which are contradictory of those in works known to be by Hippocrates, or inconsistent with the medical knowledge possessed in his day. The Alexandrian librarians set about effecting a discrimination between the genuine and the spurious; and Galen professes, in his day, to have been able to distinguish the works of Hippocrates from those merely ascribed to him. Many editions of his works have existed, and vast quantities have been written upon them. There have been 70 editions of his *Prognostics,* and 300 of his famous *Aphorisms.* The most eminent men have been his editors and commentators, *e. g.,* Celsus, Galen, &c., Amongst his biographers are to be mentioned especially Soranus, also Dacier, Le Clerc, Grimm, Sprengel, &c. The Paris edition by Littre contains a French translation and critical notes.

The following classification is made on the principle recommended by Erotian, the eldest glossator of Hippocrates, and adopted and improved by Foes:—1. Greek Editions, Venice, 1526, in folio, Aldus and Asulanus; Basil, 1538, in folio, Froben, a more complete and exact edition than the preceding. 2. Greek and Latin editions, Venice, 1588, in folio, Mercuriali; Frankfort, 1595, 1621, 1624, and 1645, in folio; Geneva, 1657, in two vols. folio; Leyden, 1665, in two vols. 8vo; the Variorum edition, Vienna, 1743-49, in two vols. folio, Stephen Mack. 3. Latin editions, Rome, 1525, in folio, Calvo; Rome, 1549, 1610, 1619, in folio; Basil, 1526, in folio; Venice, 1545, in folio, the version of Cornarius; Basil, 1558, in folio; Venice, 1575, in folio, Marinelli; Frankfort, 1596, in 8vo, Foes; Altenburg, 1806, in three vols. 8vo, Pierer, with a learned dissertation on the state of medicine before the time of Hippocrates. 4. Greek and French edition, Paris, 1811, 1815, in four vols. 12mo. 5. Numerous editions in French and other modern languages.

HIPPOCRENE. See HELICON.

HIPPODROME was the place where the horse and chariot races of the Greeks took place. The way in which the Hippodrome was constructed is found in Pausanias, though there is some difficulty in making out precisely the details. The slope of a hill was chosen to form one side of the Hippodrome; opposite to this, and forming an oblong, was raised an artificial mound, connected with the slope by a semicircular termination. At the extremity opposite to to the semicircle was the portico. From this end the chariots started, and as they kept to the right side, it was made a little longer than the left side. Thus each pair, the one of which started from the right side, and the other from the left, would have equal spaces to run. However, considerable numbers of chariots were often competing in the same race. In this case it is supposed that while the first pair started simultaneously, the second pair started just at the moment when the first were abreast of them, and so of the others. Each chariot had its own stall, from which it started when a cord was removed from before it. A bronze eagle and dolphin were used as a signal at the time of starting. The eagle was raised into the air, while the dolphin was lowered. Forming part of the axis of the Hippodrome was a wall with a goal at each end. Round this the chariots were required to pass several times. Along the sides of the Hippodrome seats were ranged for the spectators, special seats being reserved for the magistrates. See AMPHITHEATRE, and CIRCUS.

HIPPOGRYPH, a mythical animal, represented as a winged horse, with the head of a griffin. This conception has been revived by Ariosto, and still later has been reproduced by Wieland.

HIPPOLYTE, ST, a town of France, department of Gard, and arrondissement of Le Vigan, 20 miles E. by S. of the town of that name. It lies at the foot of the Cevennes, near the source of the Vidourle. Its chief manufactures are silk and cotton stockings and woollen cloths. Pop. 5700.

HIPPOLYTUS, a bishop and ecclesiastical writer belonging to the first half of the third century, whose name has recently acquired distinction and importance in connection with a recovered treatise of great value. The history of this treatise is full of interest. Among various other Greek manuscripts brought from Mount Athos to Paris in 1842, and deposited in the great national library, there was an anonymous one of the fourteenth century, written on cotton paper, and registered as a *Book on all Heresies.* It failed for some time to attract any special notice; but the attention of M. Emmanuel Miller, a functionary of the institution, being at length excited by some fragments of Pindar, and of an unknown lyric poet which it contained, he was led to examine it more closely, and to adopt the conclusion that it was a lost treatise of Origen. Under this persuasion he offered it for publication to the University of Oxford, from whose press it appeared in 1851, under the editorship of M. Miller, and bearing the title *Origenis Philosophumena, sive omnium Hæresium Refutatio.* Shortly afterwards it was studied by the Chevalier Bunsen, and after a careful and elaborate investigation it was conclusively established by him to be a genuine work of the third century, and that its real author was not Origen but Hippolytus, a presbyter of the Church of Rome, and bishop of the harbour of Rome, *Portus.* This conclusion has been confirmed by the combined labours of other scholars, especially of Dr Duncker and Dr Jacobi in Germany, and of Dr Wordsworth in England.

Previous to the recovery of this treatise Hippolytus can be said to have had little more than a mythical existence. His name was indeed a celebrated one in early Christian history. He was known to have been a bishop; but so little else was positively known of him that it remained a matter of uncertainty whether the seat of his labours was in the east or in the west. Neander (*C. H.*, vol. ii., p. 471) considered the evidence on each side to be pretty equally balanced. Yet it appears to us, on the whole, that the evidence clearly inclined in favour of the latter, even before the recent discovery. The conjecture of Le Moyne, that the Portus Romanus associated with the name of Hippolytus was Aden in Arabia,—a conjecture which Cave authoritatively carried out,—Bunsen has plainly shown to have rested on no better foundation than a misinterpretation of one of the passages in Eusebius, in which Hippolytus is mentioned (*Euseb.*, vi. 20). At any rate there can now remain no doubt, after the researches of Bunsen, that the author of the treatise *Against all the Heresies*—the Hippolytus of Eusebius and Jerome—was bishop of Portus, the new harbour of Rome, on the northern bank of the Tiber, lying opposite to the more ancient Ostia. At this time it had become a place of considerable population and importance—a bustling harbour of all nations. Here Hippolytus lived and laboured. He was a disciple of Irenæus, and his Greek education under that teacher had peculiarly fitted him to act as a sort of missionary bishop among the representatives of the various nations that were here congregated. While occupying a perfectly independent position in his own episcopal sphere of labour, he was at the same time a presbyter of the Roman Church, and shared in the deliberations of the Presbyterial council which met in that city.

In the ninth book of the recovered work, which treats of the heresies prevalent at Rome in Hippolytus's own time, and especially of that of Noetus, patronized by two Roman bishops, Zephyrinus and Callistus, and zealously opposed by Hippolytus, we have a very lively and graphic picture of the ecclesiastical state of Rome in the beginning of the third century. For this, however, the reader must be referred to the treatise itself or to the Chevalier Bunsen's analysis and reproduction of it in his third letter to Archdeacon Hare on the subject, contained in the first volume of his elaborate work on *Hippolytus and his Age.* His other works survive for the most part only in fragments.

Hippolytus, as he is seen in this work, claims undoubtedly to be regarded as a distinguished father of the Ante-Nicene Church. Of unwavering moral intrepidity, genuine honesty of character, and sense and talents inferior to none of his contemporaries, he was at the same time the predecessor of Origen in speculative power and comprehension, as well as in oratorical pretensions. He combined with more depth and knowledge than his illustrious teacher the philosophical enlightenment which Irenæus had kindled in the west. His familiarity with the course of Grecian speculation was especially serviceable in enabling him to trace the origin of the various heresies to whose refutation he devoted himself. He was the first preacher of note in the Roman Church, having elevated the mere popular exposition of the gospel, which was all that prevailed in the shape of a sermon in that church before his time, into the set homiletic address, characterized by science and eloquence, which "was his favourite mode," according to Bunsen, "of treating exegetical and polemical subjects." (J. T—H.)

HIPPONAX, a celebrated Greek satirist, was a native of Ephesus; and flourished in the latter half of the sixth century B.C. He was an ardent lover of freedom, and wrote and spoke so boldly in its favour, that Comas and Athenagoras, the tyrants of Ephesus, expelled him from his birth-place. He took refuge in Clazomenæ, where he lived and died in great poverty. Hipponax was one of the bitterest of all the Greek writers of satire, and in the classics the epithet "Pikros" is generally attached to his name. He found the subjects of his satire in the effeminacy and immorality of his countrymen, and in their superstitious idolatry. The faithlessness of women was also a favourite theme for his sarcasm; and in two of his remaining lines he says "a husband has two happy days in his life, one when he welcomes home his bride, and another when he follows her to the grave." Hipponax was in person little, and marvellously ugly, and the Chian sculptors Athenis and Bupalus amused themselves by exaggerating and caricaturing his ugliness. The enraged poet avenged himself by directing against them the most poisonous shafts in his quiver; and it is said, though the story is probably unfounded, that Bupalus, in shame and despair, committed suicide. After the death of Hipponax it was suggested by Alcæus of Messene that his tomb should be strewed with thorns and thistles, instead of roses and vine-leaves; and another epigrammatist warns the traveller against approaching it too closely, lest they rouse the wasp sleeping within. Of Hipponax's poems only about a hundred lines are extant. They have been preserved by Welcker in his *Hipponactis et Ananii iambographorum Fragmenta*, Götting., 1817, and have been published by other scholars of Welcker's day, such as Bergk and Meineke. They serve to show that the reports of his bitterness are not unfounded, but that he could relieve the severity of his satire by an abundant play of light and graceful fancy.

Hipponax introduced a curious change in the structure of the old iambic trimeter. In the last foot he substituted for the iambus a trochee or a spondee, giving the verse a lame or limping rhythm, from which it was called choliambus or iambus scazon. He also takes similar liberties with many others of the metres which he employs, and the innovation, though strange, is said to be well adapted to the general effect of the iambus, as it was moulded in the hands of Hipponax.

HIPPOPOTAMUS. See index to MAMMALIA.

HIRE, PHILIPPE DE LA, a distinguished French geometer of the seventeenth and eighteenth centuries, was born in Paris in 1640. His father, Laurent de la Hire, was a painter and engraver of considerable note, and the son's education was at first shaped so as to fit him for the same career. In his twentieth year La Hire made a pilgrimage into Italy, and while at Venice fell in with the Conic Sections of Apollonius, which determined his taste for mathematical study. His own treatise on this subject, published in 1685, under the title of *Sectiones Conicæ in Novem Libros Distributæ*, is the most important of all his works. In 1678 he was admitted into the Academy of Sciences, and was afterwards appointed by Colbert to assist Picard in conducting the surveys for a general map of France. A few years later it devolved upon him to continue, along with Cassini, the measurements of the meridian begun by Picard in 1669, and the work was progressing happily till stopped by the untimely death of Colbert. He was subsequently employed on a great number of public works, of which the most important were connected with the supply of water to Versailles and Paris. "France might have had in La Hire," says Fontenelle, "an entire Academy of Sciences." He was a quiet man, of great practical prudence, very reserved in manner, and of the most spotless integrity of personal character. His piety was as much admired by his friends as his probity. He was twice married, and two of his sons were admitted into the Academy of Sciences, the one on the score of his geometrical, the other of his botanical knowledge. La Hire died suddenly in 1718. His principal works are—

Nouvelle Méthode de Géometrie pour les Sections des Superficies Coniques et Cylindriques, Paris, 1673, in 4to; *De Cycloïde Opusculum*, ibid. 1676, in 4to; *Nouveaux Eléments des Sections Coniques, les Lieux Géometriques, la construction ou affection des Equations*, ibid. 1679, in 12mo; *La Gnomonique, ou l'art de tracer des cadrans*, ibid. 1682, in 12mo; *Sectiones Conicæ, in ix. libros distributæ*, ibid. 1685, in folio; *Tabulæ Astronomicæ, Ludovici Magni jussu et munificentia exaratæ*, ibid. 1702, in 4to; *L'Ecole des Arpenteurs, avec un Abrégé du Nivellement*, ibid. 1689, in 8vo; *Traité de Mécanique, où l'on explique tout ce qui est nécessaire dans la pratique des Arts*, ibid. 1675, in 12mo; besides a great number of *Mémoires*, in different journals, and in the Collection of the Academy. La Hire was also editor of the *Traité du Nivellement* by Picard; of the *Traité du Mouvement des Eaux* by Mariotte, and joint editor with Boivin and Thévenot of the *Veteres Mathematici Græc. et Latin.*, 1693.

HIRPINI, an inland people of Italy who inhabited the southern portion of Samnium. They are sometimes regarded as merely a Samnite tribe, by others they are looked upon as an independent nation. The country they inhabited was the wild and mountainous district traversed by the Sabatus, Calor, and Tamarus, tributaries of the Vulturnus, and on the eastern side of the Apennine ridge, the upper course of the Aufidus. In the early history of Rome the Hirpini are found identifying themselves with their Samnite neighbours against their common foes. They seem to have been subdued in the early part of the third century B.C., as in 268 B.C. Beneventum, the key of all their military positions, was colonized by Roman settlers. In the second Punic War the Hirpini appear in history for the first time as an independent people. Revolting from their old conquerors, they joined the Carthaginian invaders, and though they were unable to recapture their stronghold of Beneventum, they remained faithful to Hannibal till the defeat at the Metaurus restored the empire of Italy to his opponents. In the year of that event the Hirpini made their peace with their old masters by betraying into their hands the garrisons of their allies. From this time till the outbreak of the Social War, the Hirpini seemed to have continued steadfast in their allegiance. On that occasion, however, they set the example of revolt to the allies, and might have become formidable enemies, had not the rapid successes of Sulla induced them to repair their error by a complete submission. At the close of this war the Hirpini obtained the franchise, and do not again appear in history as an independent people. Their chief towns were Beneventum, Æculanum, Trivicum, Equus Tuticus, Murgantia, and Aquilonia. The most important of these are given under their respective heads.

HIRSCHBERG, a fortified town of Prussian Silesia, capital of a cognominal circle in the government of Liegnitz, and 25 miles S.W. of the town of that name, on the River Baber. It is the seat of the superior courts for the circle, and a great emporium for linen manufactures and hosiery. In the town and neighbourhood are bleaching works, paper-mills, and sugar-refineries; and not far off is the celebrated watering-place of Warmbrunn. Pop. 7654.

HISPANIA. See SPAIN.

HISSAR, a town of Hindustan, and the principal place of a Pergunnah, situated in the British district of Hurreeanah, within the jurisdiction of the lieutenant-governor of the N.W. provinces. The country is fertile, but labours under a scarcity of water, which detracts from its fertility. It is only watered by one small stream, namely, the Sursutty. In order to supply the means of irrigation, one of the Afghan emperors, who lived in the fourteenth century, caused two canals to be cut, one from the Sutlej, and the other from the Jumna, both of which joined at the city of Hissar, whence they are supposed to have been divided into a number of branches, so that the water was nearly all distributed over the lands, and the remainder fell into a lake called Bhedar. Under the influence of this extensive irrigation the country became fertile, and yielded two abundant crops in the year. These canals were suffered to fall to decay, but in 1825 the branch from the Jumna was cleared out by order of the British government as far as Darbah, 25 miles N.W. of Hissar, to which place it is navigable for timber rafts. The neighbouring country produces horses, camels, and cattle. The inhabitants are chiefly Jauts, with the exception of a few Rajpoots; there are also villages of Rajpoots who have embraced the Mohammedan religion. This district imports matchlocks, swords, coarse white cloth, salt, sugar, and a small quantity of rice and spices. The exports are horses, camels, bullocks, and ghee. During the prosperity of the Mogul government the town and district were considered the personal estate of the heir-apparent to the throne. Hissar was built by Sultan Feroz, who gave previous directions for the digging of the two canals above mentioned; after which he laid the foundations of the town and fortress, which he built of stone brought from the neighbouring hills of Nosa, and completed it in less than three years. E. Long. 75. 50., N. Lat. 29. 8. (E. T.)

HISTIÆA, or Oreus, in *Ancient Geography*, an important city of Eubœa, on the northern extremity of the island, and giving name to the district of Histiæotis. It was a very ancient city, and like most of the old cities of Greece, its origin is doubtful and obscure. When the Persians were finally expelled from Greece, it passed into the hands of the Athenians, and when Eubœa revolted from that people, and was again subdued, the old inhabitants of the town were expelled, and 2000 Athenian colonists settled in their stead. It was at this date that the city exchanged its original name for that of Oreus, by which it was afterwards more generally known. At the end of the Peloponnesian War the descendants of the old inhabitants were restored by the Spartans, under whose dominion the city had fallen, and to whom it remained faithful till the battle of Leuctra, when it revolted from them. In the war between Philip and the Greeks Oreus was frequently contested, and in B.C. 200 it was stormed by the Romans. Under the Romans Oreus gradually fell into decay. Some ruins of its fortifications are all that now remain to tell of its ancient greatness.

HISTOLOGY (ἱστὸς texture, λόγος treatise), the science of the minute structure of tissues. See Anatomy.

HISTORY.

History may be considered either as a department of human knowledge and intellectual exercise, or as a form of literary composition. In the observations that follow, we shall consider it under both these aspects.

I. HISTORY CONSIDERED AS A DEPARTMENT OF HUMAN KNOWLEDGE AND INTELLECTUAL EXERCISE.

1. Bacon's famous division of human knowledge or "learning," recognises it as consisting of three parts:—History, relating itself chiefly to the memory; philosophy, relating itself chiefly to the reason or understanding; and poetry, relating itself chiefly to the imagination. This distribution, though sometimes objected to, and perhaps not theoretically perfect, is substantially a good one; and it has the advantage of a massive foundation in our popular and well-understood psychology. It is not, of course, meant that in history no other faculty than the memory is called into exercise, any more than it is meant that philosophy can dispense with the memory and the imagination, or that poetry can dispense with the memory and the reason. What is meant is, that precisely as the mind may, while still acting as a whole, cast itself at one time by preference into what may be called the remembering mood, at another into what may be called the judging or reasoning mood, and at a third into what be called the imagining or creating mood, so to each of these moods of the total mind there corresponds a department of possible intellectual acquisition. History, then, according to this interpretation of Bacon's words, is that department of knowledge or intellectual exercise which lies open to the total mind when it assumes more especially the remembering or recollecting mood. In other words, it is the business of history to record or remember the past events or transactions of the world of whatever kind, and, in remembering them, to let them produce whatever further effect on the mind is consistent with the continuance of the mood named memory. This latter part of the definition is of some importance. The mind may be strictly and properly in what we have called the remembering mood; it may be recalling a past incident and dwelling on it; and yet, even while the main act is still that of remembering, the impression of the incident is not exhausted in that act, but there is a certain contemporaneous effect on the whole mind, including the feelings, the fancy, and the reason. One may remember with a purpose, or, in remembering, some feeling, or reasoning, or generalization may suggest itself; and still the act, as a whole, may be essentially that of remembering. And so in history. To record or bring to recollection past events is its characteristic function; but past events cannot be adequately recorded or brought to recollection, without at the same time affecting the feelings and the imagination, and without receiving at the same time some sort of interpretation according to the constitution of the person remembering, his acquired ideas and modes of thinking, or his immediate circumstances and purpose. No man can exercise an act of memory in common life without doing something more; nor can it be different with history, which is recollection, so to speak, on the great scale.

2. The adequate recollection of *any* past event or transaction, or of *any* series of past events and transactions is, in this sense, history. Hence the forms that history may assume are infinite. There may be a history of the transactions of a single individual during twenty-four hours; there may be a history of a club; there may be a history of a parliamentary measure or of one notable passage in the career of a nation; there may be a history of a king's reign, or of the rise, growth, and decay of some political party. Thus also we have histories of painting, histories of the steam-engine, histories of commerce, histories of cookery, histories of literature, histories of philosophy; and there is no reason why we should not have a history of history. These histories, in which certain orders of past facts are purposely selected for record and interpretation to the exclusion of the rest, are called special histories. One variety of special history—that which concerns itself with the lives of distinguished individual men—is constituted into a great department by itself under the name of *biography*. In all these varieties of history the purpose is the same—the recollection of facts exactly as they happened, and in their chronological order, so as to bring out their full impression and significance.

3. But though the adequate record of any series of past facts of whatever kind is, in this wide sense, history, we understand something different by history proper. By history proper, and especially when we distinguish it, as we generally do, from biography, we understand that kind of record which has reference to the acts and circumstances of men, as collected into communities or social masses. On this point Dr Arnold, in his *Lectures on History*, has some pertinent remarks: "The general idea of history," he says, "seems to me to be that it is the biography of a society; it does not appear to me to be history at all, but simply biography, unless it finds in the persons who are its subject something of a common purpose, the accomplishment of which is the object of their common life. History is to the common life of many what biography is to the life of an individual. Take for instance any common family, and its

members are soon so scattered from one another, and are engaged in such different pursuits, that, although it is possible to write the biography of each individual, yet there can be no such thing, properly speaking, as the history of the family. But suppose all the members of the family to be thrown together in one place, amidst strangers or savages, then there immediately arises a common life, a unity of action, interest, and purpose, distinct from others around them, which renders them at once a fit subject for history. Whether consciously or not, every society must have in it something of community; and so far as the members of it are members, so far as they are each incomplete parts, but, taken together, form the whole, so far it appears to me their joint life is the proper subject of history." According to this description, history, in its specific sense, is the adequate record of the collective acts and experiences of men when they are grouped together into societies. The societies may be large or small. A club is, to some extent, a society; a political party acting together in a state in opposition to other parties is a society; a beleaguered garrison is a society; a colony of a hundred individuals or so, engaged in settling themselves on a distant shore, is a society. In all these cases there would be the phenomenon of a common or collective life, resulting from the scattered actions of the individual atoms composing the society; and it would be the business of history to trace this common life, and to exhibit the course or career of the society as such. In general, however, the kind of society which is considered a fit object of history, is that organized society which we call a state, *i.e.*, a society having a certain *political* unity within itself, determining its own laws, and leading so far a distinct existence from other and surrounding communities, though related to them more or less. Here, again, the dimensions of the society which is made the object of study may differ. The entire ancient state of Athens, the history of which is so splendid, did not, at its highest prosperity, comprise a population of above 400,000 persons, slaves included; and mere cities were often states in the ancient world, with all that character of political unity and independence which is implied in the notion of a state. The same has been the case in modern Italy—as in the republican days of Venice, Florence, Genoa, &c. But at all times there have been political unities of much wider extent. Thus the Athenians, the Spartans, the Thebans, and others, though really political unities in themselves, and so having separate histories, became merged, even in their own fancy to some extent, in that more comprehensive unity called the Greek or Hellenic nation, the history of which collectively would be a higher undertaking. Again, even more comprehensive than the political unity called a nation, have been those vast unities, known both in ancient and modern times, called empires; consisting of aggregates of nations factitiously grasped together by conquest, intermarriages of sovereign houses, and the like. Such empires, whether so constituted as to preserve to a certain extent the inferior unities of their component parts, or so constituted as to obliterate these unities and centralize all the functions of government in one spot, become subjects of history. In short, what history demands as its appropriate object is *any* collective mass of human beings, of whatever size, presenting the characteristics of political unity, and consequently of common political life. For most purposes, in the present state of the world, the typical form of history may be considered to be the history of a nation. The *nation*—whether consisting, as in the cases of Great Britain and France, of twenty or thirty millions of people, or, as in the case of the modern kingdom of Greece, of only one or two millions—such is the form of political unity with which now, and indeed for some ages past, we are most familiar. Austria, indeed, is an empire or cluster of nations; Germany, as such, is a confederacy; and Russia, with a large national core, possesses imperial appendages. The histories of these states, accordingly, must have a corresponding character. On the whole, however, we may think of the nation as being the type, at this stage of the world, of those social aggregates of men whose common life it is the business of history to observe and relate.

4. The life of a nation, however, may be recorded either in parts or as a whole. We possess histories of both these kinds. By the record or history of a nation's life as a whole, we mean a record or history which, beginning at the first moment of the nation's recognizable existence, follows it through all its stages of growth, energy, and power, and does not quit it, until, by absorption into other nations, or by the entire breaking up of its organization, it may be considered to have lost its political identity and perished. In a retrospect of the past duration of the world, we see a wave-like series of such completed national lives. Far back in primeval time, a country or nation called Egypt looms into view; for ages it has a visible career peculiar to itself; but at a certain point, its peculiar organization is dissolved, or nearly so, before the touch of Greek or Græco-Macedonian rule; at that point, therefore, original Egypt may be assumed as having come to an end; and though other Egypts succeed, they are new Egypts rather than modifications of the old one, and must have separate histories. So also the Greek people ran their course, and though the name remained, the *thing* disappeared. So, on a still more extensive scale with the Romans, the successive stages of whose existence—first as a community of Central Italy, then as masters of Italy, then as rulers of a Mediterranean empire, which fell into ruin by degrees—are so well marked. In such instances we can have complete histories, corresponding to the complete biography of an individual man from his birth, through his youth and manhood, to his old age and death. But in the case of nations not yet dead, but flourishing and going on, it is different. The most complete history we can have in such cases is a history starting from the commencement, or, as one may say, birth of the nation so far as that can be ascertained, and carrying the nation on to its present state, whatever that may be. Thus the most complete French history would be one beginning with Druidical and Roman Gaul, and exhibiting the successive modifications of this society through which it has shaped itself into existing France. Similarly, the most complete English history would be one commencing with the Druidical Britain into which Cæsar tried to push himself, and ending with Britain, as it is now figuring in the world. Such complete histories of nations still running their course we do have, but they are not numerous. The histories of such nations are generally presented to us in portions. Thus, we have histories of France during the reigns of the Bourbons, histories of France from 1789 to 1815, histories of England from the Norman conquest till the accession of James I., histories of England during the reign of George III., and the like. Some point in the national history is selected, and the narrative is carried on a certain distance forward from that point.

5. Whichever of these forms is adopted, the true notion of history still is, that it is the biography of a nation—in the one case complete, and giving the whole life; in the other, representing some portion of the life. The question then occurs, What constitutes this common or collective life of the nation, which it is the duty of the historian to trace; where is it to be sought for; in what facts does it lie involved?

6. The answer to this question is as important as it is difficult. Generally speaking, one may say that, since the common or collective life of the nation is the resultant of all the acts and all the experiences of all the separate individuals that have lived in the nation, the larger one's knowledge of all these acts and experiences, and, in fact, of everything however minute in any way relating to any and all of the individuals of the nation singly, the better will

the purposes of history be served. No fact is too mean to be of use—no collection of facts would be too extensive for the ends of the historian. An adequate recollection, according to our definition of what that means, of all that has been thought, said, done, or suffered, by all that have lived in a community from first to last, in proper order—this would be the absolute ideal of a history of the community. The perception of the common life would be involved in such a recollection of all that went to constitute it. But necessity here imposes a limitation. We cannot, by any amount of research, know all that all the successive millions forming a community have thought, said, done, suffered, or seemed; the facts that we can know, or that, knowing, we can visibly take into account, are, at best, in every case, but a miserable percentage of this ideal aggregate. But, though this consideration impairs the perfection of history, it impairs it only to the same extent that every form of intellectual practice must be impaired by the limited nature of the human faculties. The real question is, Since all cannot be known and remembered, what is it best to know and remember? Since the facts out of which we must construct our histories in idea are but a small proportion, a mere remaining shred of that enormous, intertwined infinity of facts which actually went into the histories while the web was being woven, are there any kinds or orders of facts which, more than others, it is desirable, for the purposes of history, to secure and keep hold of? Seeing that we cannot take account of all, but may take account of some things, what things may we take account of, with the greatest likelihood of fulfilling the essential requirements of history?

7. The answer is suggested by the definition of history. If history is the account of the collective life of a nation, and if we cannot know *all* the facts that entered into the constitution of that life, we ought to inquire whether there are any *kinds* or *orders* of facts in which, more than in the others, the collective *vitality* of a nation is represented and embodied. If there are, then, whatever facts we neglect, it should not be these. But such orders of facts—vital facts they may be called—there obviously are. In every community, for example, though all contribute to the common life, all do not contribute in an equal degree. Some individuals, in every age, either from their endowments or their circumstances, or from both combined, exert a more powerful influence than the rest—contain in themselves, so to speak, a larger portion of the general life. Hence it is one of the rules of history to attend in a particular manner to the lives and actions of powerful individual men; and it is always felt that by fastening the regards on such men, describing their physiognomies and characters, and relating their movements, the problem of history is simplified, and its true end is to a considerable extent attained. The universal instinct of writers of history recognizes this fact. Again, besides the agency of powerful individuals, there is the agency in every society of what may be called powerful physical accidents, such as famines, epidemics, earthquakes, and the like; and also the agency of occasional accidents more properly social, such as great inventions and discoveries made unawares, or almost so. All events of this kind, producing as they do large effects on the whole community at once, are felt to have special claims on the notice of the historian, and are therefore always commemorated in histories. Farther, all societies are so constituted that, in the nature of things, the common vitality is not equally distributed through all parts of their mass, but the higher functions of the general life are lodged necessarily more in one part than in the others. For example, in the ancient communities, a large portion of the population always consisted of slaves, upon whom were devolved the lower industrial functions, while the higher or directing functions were exercised by an upper order of freemen, and more especially, within that order, by certain portions of it. Now, though any history of the Athenians would be defective, which did not contain a suggestion of the existence and the habits of the slave-population, which did not in fact keep continually present in the reader's imagination the thousands of slaves who were toiling daily underneath that platform of public life which was occupied by the free *demos* and its orators, yet every one knows that the real history of Athens, the actions which made it illustrious, came out of the votes and deliberations of this *demos*. And so, with modifications, in modern societies. Not only do certain scattered individuals contain in them such a share of the general vitality that they may be taken to some extent as representing the whole; but the arrangements of all communities are such that, for historical purposes, the attention need not be equally distributed over all parts, but, provided all parts are suggested and kept in view, may be most concentrated on some parts, where the higher functions are localized. In extension of this remark we may note, that in all histories it is considered important to have correct lists of the rulers or chief magistrates, and to have the physiognomy and character of each in succession pretty distinctly sketched. This is considered necessary, even when the rulers are men personally of no particular mark, or goodness, or energy; and the reason is that, since these men were the principal personages in their communities while they lived, the most conspicuous social objects, the centres of general regard, it is like reviving part of the consciousness of the generations which looked at them, to set them up again one after another in their order. Apart altogether from any effect that George IV. may have exercised personally on British history during his reign, it is to be remembered that, by the fact of his position, he was during that period an object much present in the thoughts of the British people; and hence that, by keeping him in view, we recover, as it were, so much of the mental habit of his contemporaries. Indeed, this is the principle on which the practice of dating events by the reigns of kings and the like is founded.

8. Among the various other ways in which the problem of history is simplified, none is more important than that which is afforded by the power of studying the progressive life of a nation in its art, its literature, and its philosophy or systematic speculation. In the works of art (whether in music, in painting, in sculpture, or in architecture) which a nation produces, its thoughts, its tendencies, all that is most general and characteristic in its intellectual, emotional, and moral life, is symbolized and embodied; and the due interpretation of any such series of works of art will reveal much to the historian. So with literature. The body of literature bequeathed by a nation is a living abstract of its moods, its passions, its likings, its aspirations; and a due acquaintance with a nation's literature, and, above all, with its highest national poetry, is essential to one who would write its history. Farther, and perhaps still more profoundly, the innermost life of a nation, the very principle of its life (*i.e.*, its mode of thinking), is to be gathered from the history of its philosophy and religion. What is speculation to-day becomes action to-morrow; and hence the true thread of a nation's life is to be found above all in the succession of its thoughts and maxims on those subjects which are of the greatest generality and importance to the human race. There has been a perception of this among historians, but not so distinct as there might be.

9. After all, however, history would be in a somewhat uncertain predicament, unless it could prescribe to itself a more definite and rigid path of inquiry than we have yet indicated. Although the life of a nation is to be studied in the characters and actions of its great men individually, in the traditions of great physical occurrences which have affected it, in the records of its inventions and discoveries, in accounts of the social habits and movements of its direct-

ing classes, in the portraits and dates of its successive sovereigns, in its art, its literature, and its philosophy, it is to be studied most authentically and surely in *the recorded series of its public acts.* The public acts of a nation accurately recorded, are the true backbone of every history; and whatever other information there is, must be arranged round *that.* But what are the public acts of a nation? They are the acts performed by the nation expressly as a nation. Any general movement of a nation, even when not formal, may be considered as such an act; but, for all real purposes, the acts of a nation are to be regarded as those done in the name of the nation by its government. In every society that has yet existed on the face of the earth, there has been a government of some kind or other—a certain organ or apparatus located somewhere in the body-politic, and charged, in an express manner, with the performance of the functions appertaining to the common life. It matters not whether the apparatus is a despotic sovereignty lodged in a single person, or a popular assembly, or an oligarchical council, or a system of combined powers and checks. Nor does it matter whether the apparatus remains uniformly the same, or is changed from time to time. So long as a government officiates for a nation, the nation acts through it; and hence the attention of the historian must always be fixed on the government of the nation whose life he is representing, and he must take its acts as the corporate acts of the nation.

10. Now, a nation, through its government, is capable of two distinct kinds of political action,—action referring solely to itself; and action referring to other nations. In other words, the public acts of any nation are either acts of home policy, or acts of foreign or international policy. The distinction is a simple and popular one, but it is not the less true and comprehensive. The historian must never lose sight of it. He must always keep distinct in his mind these two series of acts,—the acts of a nation, through its government, relating to its own internal affairs; and the acts of the same nation, also through its government, having reference to other nations. (1.) The acts of a nation relating to its own internal affairs are of various kinds,—popular agitations, public discussions, parliamentary debates, deliberations in council by those who exercise the government, consultations between the sovereign and his advisers, and the like; but the ultimate form which all such acts assume in every nation is that of *decrees, orders,* and *laws.* Wherever we can find a decree, an order, or a law, there we have in the most solid and authentic form an exhibition of the collective life of the nation; for every such decree, order, or law, represents the decision come to by the nation through its rulers upon some point of social necessity arising at that moment and occupying more or less the national thought. Every law represents the nation applying, at some particular moment, its collective energy and ingenuity, or even folly and prejudice, according to the forms in use, to the determination of some felt social need or emergency of the moment; and what more intimate exhibition of the collective life can there be than this? The history of every nation, therefore, is most authentically preserved in its statute-book, *i.e.*, using the word statute-book in its widest sense, in the continuous series of its written laws, edicts, regulations, &c. about the entire miscellany of its domestic matters, such as trade, taxation, crime, education, and the like, including, of course, the provisions relating to its own constitutional system or mechanism. Here the historian treads, as it were, on adamant. In other matters there may be mistakes and misconceptions; but when the historian announces the fact, that in such and such a year, a nation passed such and such an enactment, or repealed such and such an enactment, he can be sure that he is on firm ground; and if he can step from one fact of this kind to another throughout his whole narrative, he has a solid road-way. (2.) Precisely so it is in matters of international activity. The international activity of countries takes various forms. War is one form, and it has hitherto been the form predominant in the history of the world. "The history of mankind," Napoleon III. is reported to have said, "is the history of armies." But commerce is another form; and diplomacy has in all times found some scope in arrangements unconnected with war. Just, however, as all domestic political activity takes its solid issue ultimately in laws, enactments, or institutions, so all international political activity may be considered as registering itself in what are called *treaties.* The treaties of a nation, using that word in its largest sense, as including all kinds of mutual agreements among nations, are, in its external history, what the body of its written laws is in its internal. Here also the historian feels his ground firm. A treaty like that of Utrecht or that of Vienna, is like the balancing of accounts after a long term of energetic and confused action. One sees the actual result at last, and can compare it with the aims and the means.

11. Historians have always attended with some care to treaties; and, indeed, accounts of great battles and great campaigns, and of the treaties in which they ended, have always constituted a large proportion of the matter of our histories. Perhaps less attention has been paid to the internal history of countries as preserved in their statute-books; and Mr Froude has recently done good service by calling attention to this fact, with especial reference to English history, in one of the *Oxford Essays.* But there may be exaggeration even on this side. The end of history is to realize and exhibit the whole collective life of a nation; and though the main acts of this collective life are most authentically registered in enactments and treaties, much of this life, and even of what is most interesting and significant in it, would elude us, if we did not trace it through other and more subtle manifestations. For example, the collective mind and energy of Britain at the present time would be gathered but meagrely from the current series of our parliamentary enactments and diplomatic arrangements; nor does the whole river of the national life run even in the procedure which gives rise to these solid results. Hence the necessity of falling back on all those kinds of matter which we have already indicated as belonging to history; the art, literature, and philosophy of a country, the lives of its great men, &c. Hence the necessity also of neglecting nothing that can serve to make the historical recollection more true, deep, and vivid. A casual anecdote or reported saying, a glimpse of some old social custom, may often irradiate a whole tract of past time. The rule, as regards the preliminary investigation of the facts, is that by all means one ought to strive to get *as close to the transaction itself as possible;* the rule as regards the proportionate value of the facts so ascertained, is that *the "interest" of a fact is the measure of its historical importance.* This last rule may appear questionable; but duly understood, it will be found to be just. What interests one man may not interest another; but for every individual severally, true history may be defined to be whatever of the actual past he recollects with interest.

12. In order to see what are the chief *sources* of history, we have only to express in another form the substance of what we have been saying. The main sources of history may be arranged, in the order of their importance, as follows:—1. Written or otherwise registered laws and treaties; in which are embodied, in their order, the deliberate determinations of nations with respect to the successive exigencies, internal and external, through which they passed. This source is available chiefly for the history of modern nations; only scraps of the laws and treaties of the ancient nations remaining to us in their original form. 2. Public contemporary registers of notable occurrences. These, in

the express documentary form, are also most numerous for modern nations; but, for ancient times, facts may be often ascertained, and dates may be fixed, from monumental inscriptions, coins, medals, &c. 3. More general accounts of national transactions, given by those who have recorded them, and especially by contemporaries and eye-witnesses. A large proportion of what are called the "original materials" of all histories consists of such accounts, which are to be examined and checked by each other. 4. Authentic accounts of the physiognomics, lives, and characters of eminent men, and especially of eminent public men, visibly connected with national transactions. 5. Remaining works of art, and the whole surviving literature of a nation, for the period concerned, both as exhibiting the national tendencies and modes of thinking, and also as embodying incidentally particles of historical fact. 6. All miscellaneous sources of information respecting customs, costumes, food, furniture, occupations, &c. &c.; under which head, if not under some of the preceding, might be included busts, portraits, topographical views, engravings, and the like. One may also note here the occasional possibility that there is of rendering a narrative of past actions more vivid by actually visiting remarkable localities, buildings, &c., or museums of antiquities. Here the historian can communicate through his senses with actual remnants of the past. A battle-field is a portion of the earth's surface, retaining, as it were, the scar of the action which passed over it; an old castle or street is, as it were, the shell once filled with an old form of life; a suit of armour with a bullet-hole in it suggests more accurately the warrior who moved and fought within it. The most extensive use of this help to history is in travelling over countries which were the scenes of great events, so as to realize the permanent features of their scenery, whether geological, botanical, or artificial.

13. Nothing has yet been said of the distinction, recognised by Bacon, and very generally kept up since, between the civil and the ecclesiastical history of a nation. That distinction, however, though convenient, is not fundamental; and much harm may be done by regarding it as such. Obviously it is inapplicable to the history of ancient communities; and though, with regard to modern Christian nations, there are good practical reasons for attending to it, they are purely reasons of practice, and not of theory. The history of the church is a splendid subject, and may well be undertaken apart; but not because of any real isolation of the facts included in the series thus chosen for special treatment. The best history of England would also necessarily be the best history of the Church of England.

14. Hitherto we have spoken of history, in its typical form, as the account of the life of one of those organized social masses called nations; frequently, however, we use the word history in its larger and more generic sense, as involving an account of the aggregate transactions of many nations, or indeed, of the whole known world, during a certain portion of past time. Thus, Gibbon's *History of the Decline and Fall of the Roman Empire* is virtually a mediæval history—a history of all the chief nations of the world during a thousand years. And thus we rise to the very highest conception of history—that implied in such phrases as "the teaching of history," "no other instance of this is to be found in history," and the like. History, in this supreme sense, is sometimes called universal history; and the object-matter of history, so understood, is *the whole past course of humanity from the first moment of its existence to the present hour.* This is true history, in the sense we have in view when we consider it as one of the great divisions of human knowledge and intellectual exercise. The historian, in this high sense, as distinct from the philosopher and the poet, is the man who makes it his aim to have an accurate continuous knowledge of all that has taken place on this earth since it contained human beings, and, along with that knowledge, an adequate sense of its whole significance. Hypothetically, indeed, one might go farther, and say that the aim of the historian, as such, is to be able to frame to himself an adequate continuous recollection of all that has passed in time, not restricting himself to time as connected with the existence of our species, nor even to time as connected with our world only. Except, however, in as far as geology might be made to yield a history of our earth anterior to the appearance of humanity, such an extension of history is purely ideal; and history can be nothing else for us than that vast collective life of humanity as a whole, to which all national histories are but tributaries. Let us glance at the conditions and divisions of history in this aspect.

15. The first and most difficult problem of universal history, as just defined, is to fix the point of its beginning—*i.e.*, the time of the first appearance and activity of man on this planet. The unaided condition of the human race now, as regards this problem, is analogous to that of a man trying to fix the date of his own birth by his own recollection. He cannot do so. He may work his memory backwards more or less distinctly to within a few years of his birth; but the date of his birth, and the circumstances of his infant years he can know only from external information. Very much so it is with the race as a whole. Regarding the commencement of the existence of humanity on the earth, and the subsequent period of what may be called its infancy, the mere memory of humanity is necessarily at fault. Two kinds of external information are depended on for filling up the blank—the information contained in the Biblical records of the creation and beginnings of the race; and any collateral information to be derived from geological researches. In short, history, at this its first stage, is merged in theology and geology; and the historian must have his conclusions given to him from beyond the field of his own science. Even so supplied, the conclusions are not numerous. Hitherto scientific geology has not even professed to be able to determine anything precise respecting the epoch at which the earth was first inhabited by man, or respecting the conditions of its first human inhabitants. And though the Hebrew Scriptures narrate the story of the creation of mankind, and of the fortunes of its first generations, with an exactness not offered by any other record—telling of the creation of an original pair on one part of the earth's surface, tracing the descent of successive generations from that pair, and describing a great catastrophe or deluge which destroyed all these generations, with the exception of a single family, who were left to re-people the world—commentators have found the utmost difficulty in settling the dates of these events, and in casting the whole narration into a chronological form. No fewer than two or three hundred different chronological schemes have been proposed, all based on calculations from the durations of the lives of the patriarchs and other numerical data furnished by the Biblical text. The shortest of these fixes the date of the creation of man at the year B.C. 3483; the longest at the year B.C. 6984—a discrepancy of more than 3000 years. The cause of these differences is the difference existing in the passages supplying the data, between the Hebrew text of the Old Testament and the Samaritan text and the Septuagint version. The chronological scheme commonly adopted in British tables of history, during the last two centuries, is that of Archbishop Usher, which fixes the epoch of the creation at B.C. 4004, and that of the deluge at B.C. 2348.

16. Even after passing beyond this first stage in the history of the world, and assuming whatever date for the deluge he considers most probable, the historian still encounters a large tract of time respecting which, unless he proceeds implicitly on the information given in the Hebrew Scriptures, he must remain totally silent. Availing himself, however, of those parts of the Mosaic record which relate to the re-peopling of the world after the deluge, he is able to

impart a specific character to this portion of universal history which would otherwise be wanting. He can conceive it as the period of the dispersion of mankind over the earth, and of their division into nations, tongues, and peoples. And here, whatever collateral light elucidating the Mosaic account he can bring to his assistance so as to vivify his idea of human activity during this tract of time, must be derived, not, as before, from the science of geology, but from the so-called science of ethnology. The object of this science is to trace the affinities of existing nations and tribes on the earth, by the study of their physiognomical and physiological analogies and differences, the analogies and differences of their habits and mental characteristics, and the analogies and differences of their languages—so as to exhibit their genealogical descent, and, if possible, refer them back to several original stocks, springing from one root. So far as the science has yet gone, its great doctrine is that, whatever independent reasons there are for believing in the original unity of the race, yet, for historical purposes, we must conceive to ourselves humanity at the dawn of the remotest age to which its own unaided memory can penetrate, as consisting, not of one perfectly homogeneous mass aggregated on one spot, but of several distinct masses already distributed more or less densely over the various quarters of the earth, and each broken into minor subdivisions. In accordance with this general doctrine of ethnology, various schemes have been proposed. One of the most distinct and convenient is that which avers that, as far back as ordinary records carry us, we find the earth, as now, divided out among three great stocks or varieties of mankind,—the NEGRO variety, having the African continent, or the greater part of it, for their home; the MONGOLIAN variety, spread over Northern, Central, and Eastern Asia, and possibly also expatiating in America; and the CAUCASIAN variety (this is an absurd and misleading name, but no proper equivalent has yet been proposed), possessing Western Asia, Europe, and the Mediterranean margin of Africa, and subdivided conspicuously into—(1.) the *Semitic* or *Syro-Arabian* family, clustered together in the Western region of Asia between the Tigris and the Mediterranean, and in the adjacent parts of Africa; and (2.) the *Japetic* or *Indo-European* family, more widely distributed in the remaining Caucasian parts of Asia and Africa, and over all Europe. According, then, to ethnology, the business of the historian proper commences at that point of past time at which, so far as we have information, the whole or the greater part of the earth's surface can be conceived as overspread by human inhabitants of one or other of the three main types still existing—Negroes, Mongolians, or Caucasians;—these human inhabitants thinly dispersed perhaps in some parts as mere loose and roaming tribes, but in others showing a tendency to aggregate themselves into those larger consolidations which we call nations. Accepting the common chronology, he may fix this point, if he pleases, at about B.C. 2000. At that far-distant period it does appear as if the earth had been tolerably well overspread by human beings arranged very much as they now are—Negroes in Africa, south of Mount Atlas; Mongolians in Central, Northern, and Eastern Asia; and Caucasians in Western Asia, Northern Africa, and Europe; and as if already at various points these human beings had begun to form themselves into compact national masses.

17. Coming down from this point, it is the business of the historian to keep his eye roving, as it were, round the globe, on the watch for the first authentic appearances of activity on the part of any of those national masses which, he has already concluded, have been silently and obscurely forming themselves at different points on its surface. It is with communities and nations that the historian has to deal; and not till the earth furnishes him with at least one such community or nation on which he can fasten his attention, does his work properly commence. Now, here again, there are differences among historians. Some believe that, by means of records and monuments, we can carry back the histories of certain ancient nations as far as B.C. 2000, if not farther; others, more sceptical, doubt if we can go as far back as B.C. 1000, or even B.C. 800, and regard the traditions of events and the lists of kings, &c., by means of which certain of the ancient nations pushed the retrospect of their own respective histories beyond that point, as nothing more than mythology and legend. Of late this historical scepticism has certainly been exaggerated; and the researches of archæologists seem gradually to be verifying the belief that, though on the whole the period between B.C. 2000 and B.C. 800 is the domain of mythology, yet even in that period we can lay down, as it were, a causeway of solid fact respecting certain individual nations. Without entering on this controversy (which, indeed, can only be conducted satisfactorily by discussing the antiquity of each nation apart), let us enumerate those nations which, by general consent hitherto, have been reckoned as the most ancient in the world, and, as such, the first objects of the historian's solicitude:—1. In the great expanse of Negro humanity, conceived as possessing Southern and Central Africa from time immemorial, the only native consolidation that presents itself in early times with even a possible claim on the separate attention of the historian is that of the so-called *Ethiopians*, of whom we hear as a very ancient nation lying far inland beyond Upper Egypt. 2. Glancing over the vast Mongolian tracts of Asia and America, the historian encounters glimpses here and there at an early period of nations or aggregates of tribes under the vague names of Scythians and the like; but the only permanent and important consolidation whose antiquity, as maintained by itself, he feels bound to investigate, is that of the *Chinese*. The Mexicans and Peruvians of America do not come into view till comparatively modern times; so that, to all intents and purposes, America is excluded from ancient history. 3. Passing to the Caucasian regions of Western and Southern Asia, Northern Africa, and Europe, the historian is struck by the difference which these regions present. Here, instead of one nation looming into his view, he finds a considerable number of distinct nations contemporaneously or in swift succession competing for his notice. First, far to the east, and to a great extent isolated from the rest, are the *Indians*, a primeval mass of the Japetic or Indo-European race, at least claiming a high antiquity, which, like that of the Chinese, requires to be investigated. Next, clustered together in what we have defined as the Semitic or Syro-Arabian portion of the general Caucasian area—*i.e.*, in Western Asia, between the Mediterranean and the Tigris, and in the adjacent parts of Africa—are a group of Semitic nations, among which the most conspicuous are the *Egyptians*, the *Hebrews*, the *Phœnicians*, and the *Assyrians* and *Babylonians*. Lastly, in the remaining Indo-European portions of Asia, a little later in point of time, Japetic nations, such as the *Medes* and *Persians* of the Iranian table-land, and the *Lydians* of Asia Minor, are discerned rising into importance; while, if the attention is extended into Europe, the beginnings of such nations as the *Greeks*, the *Etruscans*, &c., are at the same time visible.

18. The first portion or division of universal history, therefore, is that which collects and narrates all that can be ascertained respecting the origin and early transactions of these primeval consolidations of mankind on our earth's surface, *up to that point at which their histories cease to be separate, and appear to become involved, to some extent at least, in one general movement, the tracing of which may more properly be made the business of the remaining parts of history.* Now there can be no difference of opinion as to the geographical region in which this general movement presented itself—the first heavings, as it were, of humanity in its efforts to assume that common course which it was to maintain through-

out all time. It was not in Negro Africa, it was not in Mongolian Asia, it was not in Japetic Europe; it was, beyond all question, in that portion of Western Asia (adjacent Africa included; and, indeed, the Nile was always accounted an Asiatic river by the ancient geographers) which we still think of most when we speak of "the Oriental nations," and in which, as we have just stated, a cluster of distinguished Semitic nations was in contact with one or two Japetic ones, or rather with the elements of such. Every schoolboy knows that the Indians and the Chinese, whatever their antiquity and importance, stand apart and isolated to a great extent from the regular course of ancient history, so far as we can trace it; and that the true beginnings of "world-history," as such, are to be sought for among the mutual conflicts of those famous nations clustered together in smaller masses on that portion of the East beyond or near the Levant, where, as Napoleon alleged, the human soul had ever throbbed most powerfully—the Egyptians, the Hebrews, the Phœnicians, the Assyrians and Babylonians, and the Medes and Persians. When we try to fix, however, the date or epoch at which we are to account the mere separate histories of these nations to have ended, and the general movement to have begun, there is greater room for difference. From the earliest times of which we have any glimpse, these nations, or at least the Semitic ones, were warring with each other, and making conquests. We hear of early Egyptian conquests, of early Assyrian conquests, and even of early Ethiopian conquests. The Assyrians, in particular, stand forth in our schemes of universal history as the first people who pursued a regular and known career, aiming at the subjugation and political combination of the elements that lay around them. In our traditional schemes of universal history we have presented to us three successive *Assyrian monarchies*—the first, beginning shortly after the period assigned to the deluge, and ending somewhere about B.C. 2000, when a conqueror, Ninus, extended it immensely so as to form a great empire, with Nineveh for its capital; the second, beginning at the date of this Ninus, and lasting till the death of a luxurious monarch called Sardanapalus, B.C. 876, when the empire was dismembered; and the third, a monarchy of lesser dimensions, founded amid the ruins of the second, and lasting till the destruction of Nineveh, B.C. 606, by its subjects the Medes and Babylonians, under the Babylonian viceroy Nabopolassar. After this event, according to the same schemes of history, the unity of historic interest is centred in the so-called *Babylonian monarchy*, founded by Nabopolassar, and maintained and extended by his son Nebuchadnezzar and other successors, till the year B.C. 538, when the Medes and Persians, who had in the meantime risen to a position of some importance, captured Babylon, and began a new Oriental rule. Now the historian, after due investigation, may, if he chooses, date the commencement of world-history as such either from the last Assyrian monarchy, or from the Babylonian monarchy which superseded it. For many reasons, however, in the present state of our knowledge, it seems to us that it would be better to regard the general political movement of the human race, as beginning rather at the point where for the first time the mastery is seen transferred to a nation of the Japetic or Indo-European race—*i.e.*, at the overthrow of the Babylonian empire by the Medes and Persians, B.C. 538—and the establishment of that Medo-Persian empire, which, in the hands of Cyrus the Great (died B.C. 529) and his successors Cambyses (B.C. 529-521), and Darius (B.C. 521-485), became organized by farther conquests, in which the Lydians were included, into the vast combination known as the *Persian empire.* According to this view, Cyrus is the first hero of universal history, as such; and the Persians are the first to lead the march of the general historic evolution. The best arrangement, then, as we think, for the purposes of universal history would be one which would constitute in the first place a great division by itself, under the name of PRIMEVAL ANCIENT HISTORY; assigning to this division the duty of collecting all that can be ascertained respecting the beginnings of those early consolidations of the race which we have enumerated, and of narrating their several histories, either in parallel lines where they keep separate, or otherwise where they commingle, on to that point (say the reign of Darius) where they merge in the authentic unity of the Persian empire.

19. Beyond this, the historian's course is so clear that it may be indicated briefly. The Persian monarchy, including all Asia from the Indus to the Ægean, precipitated itself upon Europe, thus determining that the world's pedigree should be continued through the Japetic nations of the West. When Darius (B.C. 490) attempted to conquer the Greeks, the earth changed its historic centre. The Greek and Hellenic race, already so nobly prepared for its honourable office (and, for the purposes of the universal historian, all Grecian history anterior to B.C. 490 would here come in by way of retrospect, including any authentic matter that might be ascertained respecting the Trojans and other Pelasgian nations of Asia Minor and Southern Europe), was inaugurated into that office at the battle of Marathon; and for a considerable period onward the main thread of universal history has to be traced in the *History of Greece.* This history, of which the Græco-Macedonian dominion of Alexander the Great and his successors may be viewed as a prolongation under different conditions from those which existed while the Athenians, the Lacedæmonians, the Thebans, &c., acted as separate or as confederate states, closes with the appearance of the Romans as a conquering people out of Italy. Transferring his regards to this imperial people (and here again the anterior of Italy itself, while the Romans were being cradled in it, as well as the by-past histories of the Carthaginians and other Mediterranean nations left out of the Persian empire, and of that of the Macedonians, but about to be included in that of the Romans, will be best managed by way of retrospect), the universal historian has a clear path in *Roman History*, as far as the fourth or fifth century of our era; at which point, by general consent, ANCIENT HISTORY closes, in the disintegration of the Roman empire by the northern races, and the commencement of a new order of things.

20. Onwards from this point there is no theoretical difficulty, though the complexity of the movement, arising from the multitude of the nations taking part in it, may occasion a practical one to the historian. MODERN HISTORY, commencing say at the year 395 of the Christian era, when the Roman empire, on the death of Theodosius, was permanently divided into the two empires of the West and East, consists, as all know, of two parts,—*Mediæval History*, which carries on the general movement from A.D. 395, at which time the empire of the West was already tottering before the attacks of the Goths and other Germanic peoples, to A.D. 1453, when the taking of Constantinople by the Turks put an end to the long-surviving empire of the East; and *Recent Modern History*, carrying on the movement from A.D. 1453 to the present time. Under both these heads, by keeping up with due skill the distinction between the "History of the West" and the "History of the East," the historian is able to include everything in its proper place. Thus, under *Mediæval History*, the "History of the West," commencing with a survey of the Roman empire of the West at the period of its decay, then passes on to an account of the Germanic peoples who were to be its destroyers, details the actions of these peoples in disrupting the empire, and forming the new societies of France, Italy, Spain, Britain, Germany, &c., and conducts the conjoint story of these societies through the eras of Charlemagne, Hildebrand, &c., to the eve of the Reformation; while the

"History of the East" (the necessary connections being exhibited throughout) includes the history during the same period of the Byzantine empire, the related histories of the Arabs, Tartars, and Turks, and to some extent that of the Slavonian nations. So, under *Recent Modern History*, there may be assigned to the department of "the West" all the transactions, national and international, of the occidental nations of Europe since 1453, including, as an important part of the story, an account of their colonizing energies as exhibited in Africa, Asia, and, above all, in America—now for the first time added to the theatre of history; while to the department of "the East" may be assigned the narrative of Turkish domination, and of interrupting Persian conquests, together with the necessary survey up to the present hour of the rest of native Asia.

21. It may be well to exhibit in a tabular form the divisions of universal history as they have been sketched in the foregoing paragraphs.

HISTORY consists of

- I. ANCIENT HISTORY, consisting of …………
  - I. Primeval Ancient History, including, after a sufficient ethnographical survey of the globe at the earliest possible date, the several histories of the most ancient known nations, such as the Ethiopians, the Indians, the Chinese, the Egyptians, the Hebrews, the Phœnicians, the Assyrians and Babylonians, the Lydians, the Medes and Persians, together with an account of the mutual actions of some of these upon each other, which resulted, after a preliminary era of *Assyrian* and *Babylonian* domination, in the formation of the *Persian empire* (B.C. 538–485).
  - II. Classical Ancient History; subdivided into ……………………………………
    - 1. *Grecian History*, beginning with the necessary retrospect of the history of the Grecian lands, and of the lands related to them prior to B.C. 490, and then carrying on the general movement, first through the true Hellenic, and then through the Græco-Macedonian era, as far as B.C. 168 or thereby.
    - 2. *Roman History*, involving a like retrospect of Italy and of the parts of the Mediterranean world related to it (Carthage, Spain, &c.), as far as B.C. 168, and then carrying all the historic world on, directly or by implication, as far as A.D. 395.
- II. MODERN HISTORY, consisting of …………
  - I. Mediæval History; from A.D. 395 till A.D. 1453, divisible into……………
    - 1. *The Mediæval History of the West*, including an account of the action of the Gothic races on the Roman empire of the West, and the histories of the societies of France, Italy, Spain, Britain, Germany, &c., formed by that action, severally and conjointly, till the eve of the Reformation.
    - 2. *The History of the East*, including that of the Byzantine empire, and the related histories of the Arabs, the Tartars, the Turks, and also, so far, of the Slavonians.
  - II. Recent Modern History; from A.D. 1453 till the present time, also divisible into ……………………………………
    - 1. *The Recent History of the West*, continuing that of the occidental nations of Europe severally and conjointly since 1453, and exhibiting these nations, and especially the Anglo-Saxon race, expatiating in Africa, Asia, and America, and there, and most notably in the last, grafting new nationalities and new forms of civilization.
    - 2. *The Recent History of the East*, comprising that of the Turkish empire, and whatever references to China and other districts of Asia are necessary to complete our view of the present state of the whole world.

Of course far more minute subdivisions than are indicated in this table would be necessary to make it perfect. Thus Roman History is divisible into the periods of the *Commonwealth* and the *Empire;* Western Mediæval History is divisible into the *Frankish Period* and the *Feudal Period;* and the History of the *United States* and of other American formations stands out as something more than a mere appendix to the recent history of the West—a kind of new development of humanity in its course towards the future.

22. The historian, then, as distinct from the poet or the philosopher, is the man who, having some such scheme of the whole past course of humanity in his mind, can fill it up with a minute and accurate knowledge of all the facts constituting its separate parts, so as to embrace the whole career of the world, from the primeval period of darkness onwards through classical, mediæval, and modern times, in one vast continuous recollection. Such men there have been and are, though naturally, as the world goes on, their number must become smaller and smaller. Niebuhr was such a man; and indeed all great scholars of ancient or modern

times have been men of this class. The terms "learning" or "erudition," as we now use them, are, in this sense, but synonyms for historical knowledge, or rather for parts of that knowledge; for what are our philologists but men of colossal memories for certain orders of those facts which universal history includes?

23. But is the historian merely a man of overloaded memory? All that enormous store of facts having been slowly acquired and treasured up, do they lie in his mind with no more of cohesion than is involved in the mere order of place and time in which they came into being? Certainly they ought not to do so; and it is to the discredit of the person pretending to be a historian if they do. Memory, as we have said, is but the name for a certain mood of the total mind; and, unless therefore the facts of universal history are themselves such as to be positively incapable of any other organization than that implied in the accidental order of their individual juxtaposition and succession, there is no reason why history should not be something more than a mere vast register of dates and particulars. We invariably assume that it is something more. We speak of "the lessons" of history. Washington, when the future organization of the United States was being discussed, drew up a list of all the most notable confederacies of states known in the world, in order that, by studying the constitution and history of each, he might assist his conclusion as to the best constitution for the thirteen American colonies. And so every day we appeal to precedents, and draw inferences from the past as to the proper course in existing social and political emergencies. We even define history as "philosophy teaching by example." And what does all this indicate but the universality of the belief that, as there is a certain invariable order of nature in the physical world, so there is in the historical or social world; that in this world also like effects must follow like causes, so that, when circumstances are the same, we have a right to infer that results will be the same? Generalizing this belief, we speak of the "course of humanity," of "the career of the race," of "the movement of human affairs," and the like; all which phrases imply that certain conclusions as to the nature and connexions of the facts recollected are involved in the recollection.

24. Speculations having reference to the mutual connections and the general bearing of the facts of past history as a whole, form what is called *The Philosophy of History.* There has always been some such philosophy. The ancient Greek historian Thucydides, for example, not only relates facts, but reasons about them; that is, he is fond of referring historical effects to what he considers their causes, and of drawing general conclusions from the story which he is telling. On this account he is often called a philosophical historian. But all the ancient historians, not mere annalists, are to some extent philosophical, in the same sense; that is, they mix reflections with their narrative, and recognise connections between causes and effects. Every one of them proceeds on the notion that, where social circumstances are similar, social results will be similar. Such men as Aristotle went much further, and tried, by studying the constitutions of different communities, and their effects on their prosperity, to establish general principles as to the best forms of government for a body-politic, and the probable destinies of this or that state. Moreover, the religious mind in all ages has always recognised a certain order in the affairs of nations, a certain course and tendency in the lives of communities as well as in the lives of individuals. Every ancient community fancied its fortunes to be under the guardianship of some deity or deities, the action of whose will and purpose might be discerned in everything that befel it. In modern times the notion of a Providence regulating human affairs, and guiding the destinies of nations, has been familiar to all noble and great minds. "What are all our histories, and records of actions of past times," said Cromwell, "but God manifesting himself that he hath shaken, and tumbled down, and trampled under foot whatsoever He hath not planted?" And in the Christian view of Providence this notion takes a much more specific form; so that all history is viewed as the gradual unfolding of that Divine scheme of which Christianity is the essence.

25. But while a philosophy of history in this sense has always existed, the idea of history as an inductive science—the idea of regarding the phenomena of society as happening according to certain fixed laws, which may be ascertained to some extent by observation, like the laws of physical nature—is comparatively recent. The honour of first distinctly expounding this idea is generally assigned to an Italian thinker, Vico (1688–1744), who in the year 1725 published a work entitled *Scienza Nuova*, or "Principles of a new Science." In this work, which, with much that was obscure and vague, contained many brilliant perceptions, Vico developed the notion of the possibility of arriving at fixed laws of social growth and decay by observing the actual course of communities. He was very sanguine in his hopes of the extent to which this science might be carried. Making it his fundamental maxim that when circumstances are the same results will be the same, he believed that after a sufficient study of the past we might be able to predict the future so certainly that we might even calculate the duration of a nation's existence. He believed that by an examination of the histories of past states it would be possible to find out the necessary and eternal career through which, with certain variations, all states must pass; and he believed that in the same way the law of the movement of humanity as a whole might be ascertained. Subsequent philosophers, both in France and in Germany, some of them without any knowledge of Vico's speculations, pursued a similar train of thought. Montesquieu, for example, did much by his inquiries into the effects of climate and the like upon the social forms and habits of nations (1748), to accustom people to a scientific manner of looking at history. Herder also, in his *Ideas towards a Philosophy of History* (1774), helped forward the same speculation. But perhaps the broadest and deepest assertion during last century of the possibility of reducing the phenomena of society and history, as well as any other kind of phenomena, within the scope of a science, was that made by Kant in his Essay entitled *Idea of a Universal History in a Cosmopolitical Point of View* (1784). The following are one or two sentences from this Essay:—"Whatever be the conception of the liberty of the will which one may form in a metaphysical point of view, its phenomena—human actions—are determined, just as well as every other kind of natural events, according to universal laws of nature. It is to be hoped that history, which is occupied with the narration of these phenomena, will, when it contemplates the play of the liberty of the human will on the large scale, discover a regular course in it; so that what seems irregular and capricious in individual cases shall appear, as regards the whole species, as a continually progressive though slow unfolding of its original tendencies. Thus marriages, births, and deaths, seem—as the free-will of man has so great an influence on them—to be subject to no rule according to which their number can be previously determined by reckoning; and yet the yearly tables of them in great nations evince that they happen just as much according to constant laws of nature as the equally inconstant rains whose happening cannot be determined singly, but which on the whole do not fail to maintain the growth of plants, the flow of rivers, and other dispositions of nature, in a uniform, uninterrupted course. . . . . One cannot forbear a certain indignation at seeing the actions of men represented on the theatre of the great world; and, notwithstanding the wisdom of individuals appearing here and there, at finding

at last everything in the gross composed of madness, of childish vanity, and frequently of childish wickedness and rage of destruction. There is here no expedient for the philosopher but that of endeavouring to discover *a design of nature* in this nonsensical course of human affairs; so that a history of creatures who proceed without a plan may nevertheless be possible, according to such a determinate plan of nature."

26. The idea thus propounded by a few of the most original minds of last century has since passed into the general belief of all thinkers, so that all are now prepared to regard the term history as including not merely the vast miscellany of the individual facts of the past, but also whatever body of truths or principles relative to the action of men in societies can be obtained by a sound study and fair generalization of these facts. Hitherto, however, notwithstanding the prevalence through Europe, and more especially in France, of a spirit of historical generalization arising from this new view of history, the body of such ascertained historical truths or principles is very small. The cause of this is the vast complexity of the facts which are the objects of social science. If in the science of chemistry we are still only in the process of arriving at laws and principles, how can we expect to be far advanced in the task of discovering the laws and principles of phenomena so much more complex than those of chemistry as are presented by human society.

27. Certain conclusions more or less certain respecting the laws of social equilibrium and social movement we have nevertheless arrived at. The principles of political economy, for example, so far as they have been established by those who have prosecuted this department of inquiry during the last century, may be regarded as inductions or generalized expressions of social facts of a particular order —those relating to social wealth—and, as such, may rank as a solid contribution to our future body of historical truths. Some conclusions of other kinds from national statistics may also be included in the same body. Nor are we without some generalizations of a more extensive nature respecting the course of human history as a whole. For example, on referring to the sketch given above of the leading divisions of universal history, certain conclusions are so obviously implied in the facts themselves that they cannot fail to suggest themselves as facts too. One such fact is, that whereas the first theatre of true historical action was limited to a small portion of the earth's surface, the whole tendency of events has been to widen that theatre, so that now the whole globe of the earth almost presents the characteristics of social organization, and is capable of a certain approach to simultaneous consciousness and simultaneous purpose. Connected with this fact is the circumstance that the agency by which this gradual social conquest and tillage, so to speak, of the globe has been effected, has *hitherto* been chiefly in the hands of the so-called Caucasian portion of humanity, and, within that portion, perhaps chiefly in the hands of the Japetic or Indo-European nations. Connected with the same fact is the interesting circumstance that the geographical order of the process has been on the whole from East to West. First the primeval Oriental fermentation affected Western Asia as far as the shores of the Mediterranean; then the Persian dynasty extended the historic stage to the Ægean; after that the Greek or Græco-Macedonian supremacy extended it to the Adriatic; next the Romans extended it to the Atlantic. Against this barrier human energy, as it were, kept dashing itself for fifteen centuries, till at last the pent-up, westward-striving force found vent, and, like the flash from a surcharged cloud, the spirit of Columbus shot to a new hemisphere. Nor does the process seem yet at an end. The westward tendency of the Americans on their continent, and the Anglo-Saxon colonizations going on in the Pacific Islands, point to the ultimate completion by history of the great circle of the earth's circumference.

28. These, however, are but generalizations from the facts of the history of the race in its obvious external aspect. Our notions as to the nature of the internal movement or course of humanity are much more vague and conjectural. Many speculative minds have propounded what they have called a "formula" of history. Vico imagined that the course of humanity was cyclical—*i.e.*, that the world, after going through a certain number of stages returned to the same point or the same set of conditions as at first, and then went through the same stages over again; and he was disposed to regard all modern history, from the date of the dissolution of the Roman empire, as a repetition, Phœnix-like, of the history of the world up to that date. Abandoning this cyclical theory, most thinkers since have adopted, as more natural, the theory of continuous *evolution* or *developement*, until all the elements of humanity shall have been finally harmonized and co-ordinated. The popular form of this theory is that which expresses itself in the word "progress"—a term which, in so far as it implies a progress from worse to better, has come into use only since the French Revolution. Less exceptionable in some respects than this term, as it is generally understood, as not so much begging the question of the absolute *character* of the evolution, is the equally popular term "civilization." The historic process, it is said, has been one of the gradual "civilization" of the race. But in what does this "civilization" consist? In a gradual change in the mode of human thought, and consequently in the mode of human activity, say some—*i.e.*, in the gradual exchange of the superstitious mode of thought for the rational or scientific, and in a gradual exchange of the occupations of war and bloodshed for those of peaceful industry! In the gradual destruction of all that interferes with individual freedom, in a gradual tendency to civil and political, if not to social equality, say others! In the gradual preparation of the human species externally and internally, said Kant, for a certain cosmopolitical organization of state which shall supersede that of nations, empires, &c., and embrace them all! In all these speculations and prognostications we can discern at least fragments of the truth. We do recognise a certain change in the mental habits of the race, depending on the growth of scientific knowledge, during the past career of the world; and along with this a change of external manners and occupations. Peaceful industry does seem on the whole to be superseding war. We do see also a gradual diffusion of privileges of all kinds; a gradual tendency to the equalization of civil and political rights; a gradual evolution of freedom for the individual human being. The abolition of personal slavery is one form in this process; the extension of the rights of citizenship in modern states is another. Lastly, we do see, with Kant, a certain tendency of humanity within, keeping pace with its geographical extension and the increase of its means of locomotion and intercommunication externally, to a possible organization which may include the whole of it. But, on the whole, the body of such conclusions which we can rank among the ascertained and positive truths of history is very small; and though all the best minds of the world are now agreed that sound politics as an art can be founded only on the scientific study of history—in other words that politics is but applied history—the confusion of political doctrines and creeds which the present state of the world presents, proves how far we are from being able to turn this maxim to any efficient account.

II. HISTORY CONSIDERED AS A FORM OF LITERARY COMPOSITION.

Our remarks under this head, necessarily very brief, may be best presented in the shape of a view of some of the leading requisites of a historian, as distinct from a practitioner of other kinds of literature:—

1. First then, to success in historical literature, it is ne-

cessary that the writer should be a man of the historical cast of mind. This is, in some sort, a truism, but it is a truism worth attending to. We all know that there is such a thing as a poetical cast of mind, and that there is such a thing as a philosophical cast of mind; but we do not so often take account of the fact that there is also a historical cast of mind, and that, just as we speak generically of "the poet" and "the philosopher," so, in the same generic sense, we may speak of "the historian," as a being intellectually distinct from either. And what is the characteristic mental habit of the historian, as distinct from the philosopher and the poet? We have already conveyed the answer to this question in our preliminary definition of history. The historian is the man who tends by preference to fall into that mood of the total mind which we call memory or recollection, as distinct from that mood which we call reasoning, or that mood which we call imagination. Such men there are. There are men to whom it is a positive constitutional pleasure to recall the memory of concrete facts and circumstances amid which they have once been—to remember persons, places, incidents, costumes, physiognomies, and physical and social particulars of every description. They delight in reminiscence and anecdote absolutely for their own sake, and amuse themselves when alone, and others when in company, by rehearsing anecdotes and reminiscences. Generally, if there are opportunities, this taste, where it exists, is extended and heightened into a liking for the antique—a passion not only for the *contemporary*, but also for the *past* concrete. It becomes a delight to gaze at an old bridge or an old building, or a spot on a heath marked by a great stone, and to know that, at such and such a time, such and such an event occurred there. Sir Walter Scott was pre-eminently such a man; Herodotus also was pre-eminently such a man. Scott and Herodotus, therefore, may stand as types of the historical cast of mind; and it is all the better to take Scott as such a type, because in him the important fact is exhibited, that a man may have the historical habit of mind strongly developed, and yet may not be a man *exclusively* of this habit. In Scott, the historian and the poet existed in remarkable combination; he imagined while he remembered, and he remembered while he imagined; he has left us both histories and poems. A combination sometimes found, and no less interesting, is that of the philosopher or speculative thinker with the historian. Sir William Hamilton, for example, is a man of colossal erudition in the history of opinion, as well as of extraordinary power as an original philosopher; and no man is so fond of casting his disquisitions into the historical form, or of appending to his disquisitions their historical elucidations. Not a few cases, also, may be found in which men, though not primarily or specifically thinkers—not themselves inclined to propound or to advocate systems of doctrine—have yet such an interest in old modes of thinking simply as facts, that they will exercise their speculative faculties to any extent in mastering the most abstruse parts of Plato, or Aristotle, or Leibnitz, or Berkeley. Sometimes, indeed, a man's historical taste chiefly shows itself in his liking for facts of this order, and neglects such concrete antiquarian details as those of costume, physiognomy, and the like. And here, of course, it is to be noted that, though a relish for all orders of antique facts is desirable in the historian, yet it is well for his completeness as a historian that his relish for certain orders of facts should be in proportion to their degrees of historic value. History, in its typical sense, being the record of the public life of a community, the historian will be the more perfect, in proportion as the facts and circumstances in which his memory delights are those in which the public life of communities is best represented and embodied. What these are we have attempted to indicate. The typical historian ought at least to have a certain interest in *political* forms, and in the recollection of *political* events.

2. The historian ought, in the second place, to be a man of the strictest veracity. But there are two kinds of veracity. There is what may be called passive veracity, or that honourable disposition of mind which makes a man himself refrain from falsehood. This, of course, the historian, as well as every man, whatever be his calling, ought to possess; and whosoever does not possess it ought to be chased and hooted from the field of history. Misrepresentation for a purpose, or for the sake of effect, when at all conscious, is but a variety of the same deliberate lying. But many men who are passively veracious are not equally conspicuous for active veracity—that is, for the disposition to spare no labour of research in order to clear out falsehood from whatever story they are dealing with, and arrive at the truth. This disposition the historian must also possess. The very word ἱστορια implies active research. Writers of history differ very much in this respect. Some men, rather than set down a date falsely, will spend weeks in trying to ascertain it, and, if they fail, will say so; others are far less scrupulous. David Hume, with all his merits as a historian, is accused of extreme indolence in the matter of research; and a story is told of the French historical writer, Father Daniel, to the effect that he "declared the study of state papers to be a task more of fatigue than of use," and that, "being shewn in the Royal Library at Paris a vast collection of original manuscripts relating to the history of France from the reign of Louis XI., he spent a single hour in turning over the volumes, and then declared that he was fully satisfied." Perhaps the French sin, in this respect, more than the Germans; though there are many splendid exceptions. As regards our own historical literature, no one who has not a large acquaintance with it can know on what a small basis of truly original research the vast pile rests, and how many works there are enjoying some celebrity (and that not as honest compilations, but really as histories), which, if examined, would turn out to be but the fourth or fifth dilutions of previous works, themselves successive dilutions of some one work, the author of which did go to original authorities. But even in using what are called original authorities, the historian has room for the exercise of research. He has to guard against two sources of error—the wilful falsification of dishonest men near the fountain-head; and the operation in all states of society and in all companies and communities, but especially in early times, of what is called the mythical or legendary tendency in human nature—*i. e.*, the tendency to imagine incidents corresponding to feelings, and then to confound the incidents so imagined with actual fact. The practised historical sense or understanding, accustomed always to weigh evidence, is on its guard against both sources of falsehood. It is only in comparatively recent times, however, that the immense importance of attending to the second source of falsehood has been appreciated. Every one knows what a revolution in the accounts of the early histories of all nations has taken place since Niebuhr first applied the theory of the Mythus to the early history of Rome as believed by the Romans themselves and recorded by all their writers.

3. *The value of any history will be in proportion to the general depth and greatness and nobility of the historian's own nature as a whole.* This ought never to be forgotten, but it is very apt to be forgotten. Seeing that the business of the historian is to recover and narrate actual facts, it is sometimes hastily concluded that it is indifferent by what kind of mind, provided sufficient diligence is used, the process of recovery and narration is gone through. We have already virtually opposed this idea. Memory or recollection, we have said, is but a mood of the total mind; and hence the character of the memory or recollection will vary according to the entire constitution of the mind which remembers or recollects. As the imagination of the poet, as the understanding of the philosopher, follows in some subtle

way the law of the total personality—so that there are poets of grand, and poets of mean imaginations, thinkers of high, and thinkers of grovelling understandings, in like manner also the memory follows the law of the personality, and there are historians of superb and historians of petty memories. It depends on the total character of the historian, in the first place, what kinds of past facts will adhere to his memory, or interest him in his researches; and, in the second place, what intensity of meaning he can find in these facts, what breadth of significance he can impart to them. Even contemporary facts, respecting which no research is necessary, are not the same things to different minds. The death of the Russian Emperor, Nicholas, for example, was externally or *per se* the same identical event to all; and yet, as that intelligence was swept abroad over Europe, it became, so to speak, a thousand different "facts" simultaneously to the thousand different minds which it touched. And so, under more complex conditions, with the facts of past history. "The greatness of the historical literature of any period therefore" (if we may here repeat what we have said elsewhere), "or the greatness of any individual as a historical writer, depends ultimately on the general richness of the human nature which that period or that individual brings to the investigation of the past. A mass of facts, in themselves unalterable, is the material of every history, but it depends on the spirit which the historian breathes through the mass what the history shall be. Not only may history be, but necessarily every history is, saturated with the spirit of the historian in all its peculiarity. History is, and can be nothing else, than the past represented by the present; what the representation, therefore, in any case shall be, depends, no doubt, partly on the actual matters represented, but at the same time also on the power which represents them. History, accordingly, is a form of literature affording scope for genius, for high moral purpose, for original and inventive power, equally with any other. Herodotus, Thucydides, Tacitus, Voltaire, Gibbon, Hume, Robertson—do we not feel that in the hands of such men historical writing became, as much as any other could, a medium through which they could perform the whole function of their being, both in so far as it was good and in so far as it might be bad? Shut up a hundred different historians in as many different rooms, each with the same materials for an account of the same selected transaction; and then, necessarily, the hundred narratives that will be produced at the end of any given period, although all so far identical in substance, will each bear the stamp of the author's individuality—of his acquired knowledge, his prevalent habits of feeling, his whole philosophy of life." Applying these remarks, one might classify known historians according to certain broad differences of the human constitution generally. Some historians are poetic and pictorial, others are speculative and philosophical, others are stern and severely judicial; some are grave and earnest, others are light and satirical, in their manner. On the whole, the historical cast of mind may be associated with almost any conceivable combination of other mental habits and faculties; and almost all varieties of character and intellect may find congenial scope in history. The persons perhaps whom it would be most desirable to exclude from this department of literary exercise are men labouring under the influence of special polemical crotchets. Such men ought to write pamphlets, and take their illustrations from history, but ought not to write formal histories.

4. The historian is bound to be acquainted with all those general conclusions or inductions relating either to social life as it may be now observed, or to the order of social events in the past, which may be considered so far established as to constitute historical or political truths. The body of such truths, we have said, cannot yet be said to be numerous; but so far as they exist, they ought to be known to the historian, and to form part, so to speak, of his historical creed. Thus, if there are any generalizations that can be esteemed sound and valid as to the invariable course of nations, or as to the successive phases of human thought in the past, or as to the tendency of humanity as a whole, or as to the influence of climate and other physical causes on social and political conditions, these ought indubitably to be carried by the historian along with him, as so much fixed science, in his own particular researches. It is needless to point out how this applies to the truths of political economy, as one branch of social science, so far as these are accepted and agreed upon.

5. The historian, over and above the foregoing requisites, must have acquired for himself by study and practice a certain very complex *art of historical writing and arrangement.* The full illustration of this important matter is beyond our present limits. Suffice it to say, that, though there are many varieties of historical art—though the art of a Gibbon, for example, is very different from that of a Macaulay—yet the essence of all good historical art, in the case of what we have called the typical form of history, seems to lie in a distinct recognition by the historian of the fact that, in writing a history, he is writing the life of a nation. Just as, in biography, the essential notion is that of an original organism moved through certain sets of circumstances which act upon it and modify it, and just as the biographer has always to keep in mind this distinction between the man as he is at any moment, and the circumstances through which he is passing at that moment, so it is in history. Here, also, there is always a certain already existing organism—*i.e.*, the total social being and constitution of the nation up to the moment under notice; and there is, then, farther, the set of new conditions through which that organism is about to pass. Translate this into the language of practical art, and it may be said that the historian has at every point to keep the balance fair between the two processes of description and narration—description being the process which takes account of facts as they exist contemporaneously, and narration the process which follows facts in their sequence. In other words, good historical art consists of a judicious blending of descriptive surveys of social states with narrative accounts of social transactions. (1.) *Historical description.*—It has always been accounted part of the business of a historian to give broad descriptive surveys of what are called "states of society," "states of civilization," and the like. Perhaps, however, it might be to the advantage of history if a greater proportion of the whole duty of the historian were accomplished by means of this art of contemporaneous surveys. For example, there is no method according to which, as we conceive, the history of England could be better written, than some method by which a great part of the vast work might be achieved in a series of "cross-sections," or broad contemporaneous surveys of the whole life and civilization of the English nation at important and well-selected epochs of its progressive existence; the intervening periods between these "cross-sections" being filled up by the plan of narration. In general, historians confine themselves too much, and especially when treating of remote periods, to the narrative plan. As examples of the other plan of contemporaneous description, we may refer to Mr James Mill's elaborate account of the civilization of the Hindus in his *History of British India*; and to Mr Macaulay's well-known survey, on such different principles, of the state of British society prior to the Revolution of 1688. In such cases as these, historians, of course, proceed on a certain instinct, teaching them what orders of facts ought to be included in such a survey to render it complete. Mr Mill's instinct in this case was founded on his previous habits of political criticism and analysis; Mr Macaulay's was more purely artistic. Science, however, might here come to the assistance of art. It would be possible, we

think, once for all, to draw up, so to speak, a schedule of the essential particulars that ought to be known about any nation, in order to complete the survey of its civilization, and to arrange these particulars in their proper order, commencing say with the geographical and geological features of the country which the nation inhabited, and proceeding on to the most intricate parts of the national polity; and then, the best historical artist would be the one that, purposely or instinctively, should best fill up the schedule, or comply with its requisitions. (2.) *Historical Narration.*—Not to mention other matters under this head, we would only point to the importance in every narration of regularly *beating time*—*i. e.*, not only accurately inserting dates, but distinctly keeping the flight of time, day by day, month by month, and year by year, present in the imagination of the reader. Historians differ very much in this respect. Some are so lax that the reader hardly knows, until he makes the calculation for himself, how long the war he is reading about has already lasted, or what is the age of the general.

6. It only remains now to pass our eye along the course of universal literature, so as to enumerate those who, according to the general judgment of their own and of other nations, have distinguished themselves most in the department of history, and may therefore take their places in the list of the chief historians of the world:—

I. Primeval Historians.—Here the sacred historians of the Old Testament stand alone; and it is from them, in conjunction with the retrospective narratives of some of the Greek historians, especially Herodotus, and in conjunction also with archæological research, as in the investigation of the monuments of Egypt, and of those recently disinterred at Nineveh (and probably the same process may be yet applied to many others of the famous sites of ancient oriental civilization), that all our historical knowledge of primeval times is to be derived.

II. Classical Historians.—(1.) *Greek Historical Writers.*—This list is headed by Herodotus, the "Father of History," and a man whose name the whole human race is bound to hold in reverence, as that of one of the truest men of genius that ever lived. Then come, in order, Thucydides, Xenophon, Polybius, Dionysius of Halicarnassus, Diodorus Siculus, Arrian, and Plutarch; to whom may be added the Jewish historian Josephus, and the ecclesiastical historian Eusebius. (2.) *Latin Historical Writers.*—The most illustrious names in this list are those of Sallust, Julius Cæsar, Livy, Suetonius, and Tacitus; but other minor names might be added. Livy and Tacitus are pre-eminently the Roman historians.

III. Mediæval Historians.—(1.) *Latin Historians of the Western Nations.*—A vast proportion of the mediæval history of the western nations is buried in the legends or lives of the saints; but each nation had its independent chroniclers of political and ecclesiastical events, some of whom rose to the dignity of historians. Among these Gregory of Tours, who lived in the Merovingian times of the Frankish monarchy, and wrote an *Ecclesiastical History of the Franks*, deserves mention. There were also some notable chroniclers and biographical writers in the age of Charlemagne; and France produced some good contemporary historians of the Crusades. No country, however, was richer in historical writers during the middle ages than England. The venerable Bede, in the eighth century, was a man of true historical genius; and to the twelfth, thirteenth, fourteenth, and fifteenth centuries, belonged a series of able Latin chroniclers, of whom the most distinguished are Geoffrey of Monmouth, William of Malmesbury, Matthew Paris, Higden, Knighton, and Walsingham. The Scottish historian Fordun belongs to the fifteenth century. (2.) *Byzantine Historians.*—Under this name is included a considerable series of rather petty writers, natives of the Greek or Eastern Empire, from its separation from the West to its final destruction by the Turks. Among these were Procopius, Agathius, Menander, John of Epiphania, Theophylactus Simocatta, and the well-known Anna Comnena, daughter of the Emperor Alexius Comnenus. (3.) *Oriental Historians.*—In the remarkable development of the literary genius of the Arabs, consequent upon the impulse given to the race by Mohammed, history was not neglected. The Spanish Arabs had their special historians; and Turkish and Persian historians of the middle ages are also mentioned. Of Indian and Chinese historians we can say nothing, though these were not wanting.

IV. Modern Historians.—Since the rise of the vernacular literatures of the various modern nations of Europe, we are able to count a number of distinguished men in each, who have devoted themselves, some exclusively, others in part, to historical writing, and have there won their literary laurels. (1.) *English Historical Writers.*—Among these, passing over such valuable early chroniclers as Holingshed and Stow, and such metrical historians as Barbour and Wyntoun, may be mentioned—Knollys; Sir Walter Raleigh, in virtue of his *History of the World;* Bacon, in virtue of his *History of the Reign of Henry VII.;* and Shakspeare himself, in virtue of his historical plays, called, by himself and his contemporaries, *Histories.* Next (passing over minor names) may be mentioned the party-historians Clarendon and Burnet; succeeded by the splendid series of British historical writers of the eighteenth century—Swift, Defoe, Hume, Smollett, Warton, Lord Lyttelton, Lord Hailes, Dr Henry, Dr Robertson, and Edward Gibbon. All in all, Gibbon, in virtue both of the immensity of his task, and of the admirable industry and art with which it was executed, has the highest place assigned to him among British writers of history; and he is in many respects, though not in all, the type of a great historian. After the time of Gibbon no man had a more powerful influence on the historical literature, not of Britain alone but of all Europe, than Sir Walter Scott; all the efforts of whose genius were, in a sense, historical, and some of whose works, though not his best, were expressly histories. Historical writers contemporary with Scott, and each having characteristic excellences, were James Mill, and Mackintosh; and, coming down to our own generation, what a constellation in our historical literature (we shall not attempt to classify the stars according to their magnitudes) is represented by the names of Tytler, and Arnold, and Alison, and Napier, and Macaulay, and Carlyle, and Thirlwall, and Grote. Belonging to the same constellation, in virtue of the language in which they write, are the American historians, Washington Irving, Bancroft, and Prescott. (2.) *French Historical Writers.*—In this list, which may be considered to begin with De Ville Hardouin and De Joinville in the thirteenth century, the greatest names in times anterior to the Revolution are those of the vivid and and picturesque Froissart, Philip De Comines, Thuanus (who, however, wrote in Latin), D'Aubigné, Brantome, Perefixe, Sully, the Jesuit Daniel, Vertot, Rollin, the illustrious Bossuet, Basnage, Fleury, Rapin, St Simon, Du Cange, Voltaire, Montesquieu, Raynal, and Rulhières; to whom, since the Revolution, have been added, besides many of inferior note, such men as Sismondi, Barante, Guizot, Capefigue, the two Thierrys, Mignet, Michaud, Thiers, Michelet, Merimee, Lamartine, and Louis Blanc. In no department of literature has France recently been so prolific as in history; and perhaps, on the whole, no other country has such a cluster of eminent living historians. At the head of what is perhaps the most characteristic school of French historians—*i. e.*, those who are distinguished by their passion for historical generalization, as well as their mere powers of narration—stands M. Guizot. (3.) *Italian Historical Writers.*—Of these the chief are, in the sixteenth century, Macchiavelli and Guicciardini, with some lesser men, such as Varchi, Bembo, Sarpi, and Davanzati; and in more recent times, Davila, Maffei, Muratori, Tiraboschi, Botta, Micali, Bossi, Colletta, and Pignotti. (4.) *German Historical Writers.*—Passing the Magdeburg centuriators and other ecclesiastical historians of the sixteenth century, who wrote in Latin, we have to come down to the eighteenth century for any German historical writers of importance. To that century belong Heyne, Schwekh, and other contributors to a *Universal History* then published; to whom have succeeded such men as Eichhorn, Müller, the great Niebuhr, Heeren, Schlosser, Rotteck, Menzel, Lappenburg, Von Hammer, Raumer, Neander, Ranke, and Bunsen. In "learned" history, and in patient research, the Germans are unparalleled. (5.) *Spanish Historical Writers.*—Among their chief historians the Spaniards reckon Palencia, Bernal Diaz, Pedro Martyr, and Valera, in the sixteenth century; Morales, Mendosa, Mariana, Herrera, La Puente, and De Solis, in the seventeenth; since which time Spain has produced as little in history as in other kinds of literature. (6.) *Historical Writers of the Scandinavian Countries.*—The Danes count among their eminent historians Gram, Holberg, Malling, Moller, and Grundtvig; the Swedes count among theirs Tegel, Dalin, Botin, and Silferstolpe. (7.) *Slavonian Historical Writers.*—Among the most celebrated *Russian* historians, after Nestor, a monk of the twelfth century, are Tatischeff and Karamsin. The *Poles* have had not a few eminent historians; and Palacky is the greatest historian of the *Bohemians.* (8.) *Greek Historical Writers.*—Of modern Greek historical writers the most distinguished is Tricoupi. (D. M—N.)

HIT, the ancient *Is*, a town of Asiatic Turkey, pashalic of Baghdad, on the W. bank of the Euphrates, in N. Lat. 33. 43., E. Long. 42. 27. It contains about 1500 houses, chiefly of clay, one or two storeys in height. The streets are narrow, dirty, and frequently steep, rising one above another along the side of the hill on which the town stands. A graceful minaret and some tombs are the only structures worthy of notice. The never-failing fountains of bitumen still produce that substance as plentifully as when old Babylon was built. The inhabitants are employed in boat-building, and in the preparing of wool, bitumen, naphtha, and salt.

HITCHIN, a market-town of Hertfordshire, 14 miles N.W. of Hertford. The parish church is a handsome building, with a fine porch, and an altar-piece by Rubens. It has a free grammar-school, an infirmary, mechanics' institute, and savings bank. Malting is extensively carried on, and straw-plaiting affords employment to many persons. There are also several breweries and a silk mill. Market-day, Tuesday. Pop. (1851) 5258.

HITTITES, the children or descendants of Heth, formed one of the tribes of Canaanites which occupied Palestine before the Israelites. They lived in the mountains of Judea round Hebron, and retained their nationality even after the return of the Israelites from exile. The "kings of the Hittites" are often mentioned in connection with the kings of Syria; and in the days of Joram their alliance with the Egyptians was an object of dread to the besieged inhabitants of Samaria.

HIVITES, one of the tribes who occupied Canaan previous to the subjugation of the country by the Israelites. They occupied the N. and N.E. of the land.

HOADLEY, BENJAMIN, was born at Westerham in Kent in 1676. He was made bishop of Bangor in 1715, of Hereford in 1721, of Salisbury in 1723, and of Winchester in 1734. He died at Chelsea in 1761.

He attracted attention at first by his controversy with Bishop Atterbury in 1709. At this time the Tory party, which he opposed, were in favour at court, so that no patronage was to be expected from them; and he owed the rectory of Streatham to private favour. The House of Commons, however, were so pleased with the manner in which he defended himself against the Tory Atterbury, that Hoadley's name was mentioned in the address to the Queen as a champion of liberty, both civil and religious. He developed his principles in his tract on the *Measure of Obedience to the Civil Magistrate.* But in 1714 Queen Anne was succeeded by George I., and a revolution now took place in the court politics. In 1715 Hoadley was raised to the bishopric of Bangor; and in 1717 the celebrated *Bangorian Controversy* arose. It began by Hoadley's publication of his views on the text, "My kingdom is not of this world;" in regard to which he maintained that Christ had left behind him no such authority as that claimed by churches, and that this was the best way of answering the arrogant pretensions of the Church of Rome. These views gave great offence both to High Churchmen and Dissenters. He was attacked from all quarters. William Law is considered his ablest antagonist. The controversy raged for three years without any immediate result. From his *Discourses on the Terms of Acceptance*, it is obvious that he rejects the five points of Calvinism. He has been regarded as the leader of the Rational divines of the Church of England, and as verging towards Unitarianism. He was a friend of Dr Samuel Clarke, of whose life, writings, and character he wrote an account. He also wrote an account of the *Nature and End of the Sacrament*, and a *Letter to Clement Chevalier.*

HOANGHO. See YELLOW RIVER.

HOBAL, the name of the sun-god of the Arabians, generally depicted in Arabic mythology as surrounded by the gods of the 360 days.

HOBART-TOWN, the capital of Tasmania or Van Diemen's Land, is situated in the southern part of that island, on the right bank of the estuary of the Derwent, about 20 miles from the sea, in N. Lat. 42. 53., E. Long. 147. 21. Hobart-Town was founded and made the seat of government by lieutenant-governor Collins in 1804, and was named after Lord Hobart, then secretary of state for the colonies. It is regularly and neatly built on gently rising ground, inclosed by an amphitheatre of lofty and well-wooded hills. A small rivulet, called Hobart-Town Creek, flows through the town. The buildings are of brick, or a dark-coloured freestone, abundant in the neighbourhood. Many of the public buildings are handsome edifices, especially some of the churches. The government house is a large and irregular pile of building, originally built on a small scale, and enlarged as necessity required; but a new one is in course of erection, if not now finished. Among its other buildings are the custom-house, court-house, female house of correction, new market-house, and military and prisoners' barracks. There are also a magnetic observatory, high school, mechanics' institute, and several literary and scientific societies. One of the great advantages of Hobart-Town is its fine harbour, where ships of any burden may lie in safety close to the shore. Large quays and basins have been constructed; and along the water-side are ship and boat building yards. Pop. (1847) 21,419.

HOBBEMA, MINDERHOUT, or MINARD, a famous landscape painter of the Flemish school, was born in Antwerp about the beginning of the seventeenth century. His personal history is a total blank. The only fact in it that can be relied on as even approximately true is that he died at a very advanced age in 1699. His landscapes, which are now rather rare, are extremely simple in their structure; but his management of perspective, and his conduct of chiar-oscuro, enable him to express vast distances in a few square feet of canvas, and to imprint a distinctive and marked character on the homeliest scenes. His execution is wonderfully careful, yet so well harmonized, and so light and graceful, that each separate piece is in itself a perfect gem of art. His style bears so strong a resemblance to that of Ruysdael that many of his pieces pass under that artist's name. The figures in many of Hobbema's pieces were supplied by Teniers and Ostade, which has contributed greatly to enhance their value. Some of his *chef d'œuvres* are in this country, his best authentic pieces being in the galleries of the Peel family.

HOBBES, THOMAS, the philosopher of Malmesbury, was born 5th April 1588. While merely at school, he translated the *Medea* into Latin verse. At the age of fourteen he went to Oxford, where, for five years, he studied logic and the Aristotelian philosophy. After this he superintended the education of the son of the Earl of Devonshire. The friendship formed between Hobbes and this noble family continued through life. Travelling with his charge in France and Italy, he became acquainted with the most eminent philosophers, and greatly enlarged the field of his observations. Returning to England, he formed a friendship with Bacon. In 1628 he published his translation of Thucydides. It had a political object in view, being intended to warn his countrymen against the vices of democratic government. By this time he had lost both patron and pupil by death, and his second visit to France and Italy was along with the son of Sir Gervase Clifton. He now applied his vigorous intellect to mathematics. Returning to England he was entrusted, in 1631, by the dowager Countess of Devonshire, with the charge of another son, with whom he made a third visit to the continent. It was during this visit that he formed an intimacy with Father Mersenne, Gassendi, and Galileo. In 1634 he republished his translation of Thucydides, with a dedication to the young Earl of Devonshire. In 1637, upon returning to England, the violent commotions which were agitating the country increased his dislike of democracy. In 1640 he thought it prudent to escape from the impending storm in his own country, and retired again to France. Through his friend Mersenne, he became acquainted with Descartes. These two philosophers, however, did not altogether agree. In 1642, impressions of his famous work *De Cive*, which he had been preparing for some time, were distributed amongst his friends. It was published in Holland six years afterwards, with a French translation. The principles promulgated in this work could not fail of gaining him many enemies. In 1645 he entered into a mathematical controversy about the quadrature of the circle, and such was his renown, that he was appointed, in 1647, mathematical tutor to the Prince of Wales, who was at that time in exile at Paris. In 1650 he published in London his able treatise on *Human Nature*, and *De Corpore Politico*. In 1651 he published his celebrated work *Leviathan*. Under the emblem of the great sea-monster, he represented the body politic. This work exhibits the combination of Hobbes' principles in politics, morals, and religion. He was attacked by all denominations of religionists. He had greatly offended the Popish party, by the exposure of priestcraft, which occurs in *Leviathan;* and, in consequence, thought it prudent to quit France and return to England. Spending the year 1652 in England, he became acquainted with Harvey, who discovered the circulation of the blood; with Selden, and with Cowley, who wrote a Pindaric ode in his praise. In 1655, his great mathematical war commenced with Wallis; and shortly after he answered Bishop Bramhall on *Liberty and Necessity in Human Actions.* Bramhall, however, had written ten years before, and was now dead. In 1660, upon the restoration of Charles II., Hobbes, who had been his mathematical preceptor in Paris, was received into favour, assured of protection, and had L.100 a-year from the king. He applied himself now with increased vigour to the study of mathematics. The storm against his *Leviathan* and *De Cive* began again to rage. These books were censured by parliament in 1666; and upon the bringing in of a bill to punish atheism, he became apprehensive for his personal safety. However, the storm passed over, and he thought of publishing a new and magnificent edition of his works, which, however, he was obliged to do abroad. So great was his fame, that foreign ambassadors were anxious to see the man whose name was spread throughout Europe. Cosmo de' Medici, Prince of Tuscany, received from Hobbes a collection of his works, together with his portrait, to take to Florence. At the advanced age of eighty-six, Hobbes translated part of Homer's *Odyssey.* The translation was so successful, that he proceeded with the remainder, and in 1675 published a translation of both *Odyssey* and *Iliad.* He died in Derbyshire on the 4th December 1679, in the 92d year of his age.

Hobbes was one of those remarkable men, who, in critical times, have their little as well as their great qualities brought out very prominently. His egotism appears in numerous passages of his metrical autobiography, written at the age of eighty-four. He mentions the circumstance of his being prematurely born, owing to the fright taken by his mother upon hearing of the Spanish Armada approaching the coast. However, his premature birth did not prevent him from living to the great age of ninety-two. The day of his birth happened to be Good Friday, and his admirers did not hesitate to compare him to Jesus Christ, who left the world on the same day that Hobbes came into it,—and both for the same purpose,—the salvation of mankind! He had no pleasant recollection of the drill to which he had to submit in learning the moods and figures of the logicians; he says he learned them slowly—did learn them however, and then cast them away. He mentions, quite complacently, that he was ranked amongst philosophers, and freely speaks about his work *De Cive*, "It pleased the learned, and was entirely new. I was translated into various languages and read with applause. I was known by name afar among the nations." He complains of being misrepresented to the king, whose presence he had been forbidden; and calling to mind the fate of Dorislaus and Ascham, he says he felt the terrors of proscription. His life was in a great measure spent in fear, which he himself admits: for speaking of his birth, he says his mother brought forth twins—himself and Fear,—

> "Meque metumque simul."

Atterbury declares, that these terrors were terrors of conscience. Hobbes gives his own opinion of *Leviathan.* After saying that it had been attacked, he adds, "It stood all the firmer, and my hope is, that it will stand through every age, defended by its own strength."

Morose and impatient as Hobbes was of contradiction, he had not a little to endure which would have disturbed the equanimity of sweeter tempers than his. He saw his writings misunderstood, and then misrepresented by large masses of men, and the transition was easy from misrepresentation of his writings to gross aspersions of his personal character. Amongst his detractors, Bishop Fell was guilty of the most dishonourable procedure. Antony Wood, the friend of Hobbes, had published in English a work in 2 vols., containing an account of Oxford, as to its antiquities, and the eminent men who had been connected with it. In this work was a very favourable notice of Hobbes. Bishop Fell translated the work into Latin, but the complimentary epithets applied to Hobbes were struck out, and abusive ones placed in their stead. In several cases whole sentences of a eulogistic character were altogether expunged. Hobbes points out these alterations and erasures; and considering the injury done to Wood, to say nothing of himself ("fama enim mea, qualiscunque est, jamdudum pennata evolavit irrevocabilis"), he contemplates, for a moment, the propriety of raising an action against Fell: "Nulla ergo causa est ut publice cum eo litigem." But the little public sympathy to be expected in a matter where squabbling scholars are concerned, decided him against it.

Bold and original as Hobbes was in announcing his dogmas, yet when persecution on account of them came near him, he betook himself to unmanly subterfuges. He even defends himself for writing ambiguously in certain cases. His political system being one of expediency, enabled him to shift his ground, and in doing so, the subtlety of his metaphysical intellect was more than a match for the majority of those who endeavoured to detect and expose inconsistency. Yet it is remarkable, that with his clear and subtle intellect, it was from a misconception of some of the most elementary truths of mathematics, that he kept up his great war with Dr Wallis, professor of mathematics at Oxford. Numerous answers were written on both sides, and the virulence with which the fighting was carried on, extended even to the titles of the books. Thus, the *Six Lessons to the Professors of Mathematics in Oxford*, of Hobbes, was answered by the *Due Correction for Mr Hobbes, or School Discipline for not saying his Lessons Right*, of Wallis.

As to his deportment and manners, they are thus described by Dr White Kennet, in his Memoirs of the Cavendish family. "The Earl of Devonshire," says he, "for his whole life entertained Mr Hobbes in his family, as his old tutor rather than as his friend or confidant. He let him live under his roof in ease and plenty, and in his own way, without making use of him in any public, or so much as domestic affairs. He would frequently put off the mention of his name, and say, 'He was a humorist, and nobody could account for him.' There is a tradition in the family, of the manners and customs of Mr Hobbes, somewhat observable. His professed rule of health was to dedicate the morning to his exercise, and the afternoon to his studies. And therefore, at his first rising, he walked out, and climbed any hill within his reach; or, if the weather was not dry, he fatigued himself within doors by some exercise or other, to be in a sweat; recommending that practice upon this opinion, that an old man had more moisture than heat, and therefore by such motion heat was to be acquired and moisture expelled. After this, he took a comfortable breakfast; and then went round the lodgings to wait upon the earl, the countess, and the children, and any considerable strangers, paying some short addresses to all of them. He kept these rounds till about twelve o'clock, when he had a little dinner provided for him, which he ate always by himself without ceremony. Soon after dinner he retired to his study, and had his candle, with ten or twelve pipes of tobacco, laid by him; then shutting his door, he fell to smoking, thinking, and writing for several hours. He retained a friend or two at court, and especially the Lord Arlington, to protect him if occasion should require. He used to say, that it was lawful to make use of ill instruments to do ourselves good. 'If I were cast,' says he, 'into a deep pit, and the devil should put down his cloven foot, I would take hold of it to be drawn out by it.' After the Restoration, he watched all opportunities to ingratiate himself with the king and his prime ministers; and looked upon his pension to be more valuable as an earnest of favour and protection, than upon any other account. His future course of life was to be free from danger. He could not endure to be left in an empty house. Whenever the earl removed he would go along with him, even to his last stage, from Chatsworth to Hardwick. When he was in a very weak condition, he dared not to be left behind, but made his way upon a feather-bed in a coach, though he survived the journey but a few days. He could not bear any discourse of death, and seemed to cast off all thoughts of it. He delighted to reckon upon longer life. The winter before he died, he made a warm coat, which he said must last him three years, and then he would have such another. In his last sickness his frequent questions were, Whether his disease was curable? and when intimations were given that he might have ease, but no remedy, he used this expression, 'I shall be glad to find a hole to creep out of the world at;' which are reported to have been his last sensible words; and his lying some days following in a silent stupefaction, did seem owing to his mind more than to his body."

For an analysis of Hobbes's philosophy and its influence on English thought and speculative science generally, see Sir James Mackintosh's Preliminary Dissertation prefixed to this work.

HOBGOBLIN, a term in the fairy mythology. According to Skinner it is equivalent to rob-goblin, Hob being a familiar name for Rob or Robin; but Wallis and Ennius derive it from the Anglo-Saxon *hoppan*, to hop; because the fairies seemed to hop on one foot rather than walk.

HOBLERS, or Hobilers, *Hobelarii*, in England, feudal tenants bound to serve as light-horsemen in times of invasion.

HOB-NOB (Saxon *habban, næbban*, to have, not to have), a colloquial expression signifying "hit or miss," and originally applied to anything that depended on chance. It hence came to be used as an invitation to reciprocal drinking.

HOCHE, Lazare, one of the noblest spirits and ablest generals of the French Republic, was born of humble parents in 1768 at Montreuil, near Versailles. At the age of sixteen he enlisted, and his republican zeal, aided by his genuine military skill and knowledge, raised him so rapidly through the lower grades of the service, that at the early age of twenty-four he was entrusted with the command-in-chief of the army of the Moselle. He justified the high hopes he had inspired by defeating the Austrians in several engagements, and driving them out of Alsace. Incurring the suspicions of Robespierre, he was recalled from the frontiers and thrown into prison, and was only saved from the guillotine by the timely fall of that redoubted leader on the 9th Thermidor 1794. Released by the Convocation, he was sent into La Vendée to bring to a close the bloody war which the republic was then waging with the royalist peasantry of western France. By the noble chivalry and generosity of his character, as much as by strategic skill, he succeeded in pacifying La Vendée and Brittany. After accomplishing this task, in which the noblest blood of France had flowed like water, he was appointed to head the army of invasion which the French were organizing for the conquest of Ireland; but the fleet in which he embarked was destroyed or dispersed by storms, and Hoche was himself with difficulty saved. In the following year he was sent to the eastern frontier to act against Austria; and by a series of masterly manœuvres he hemmed in the Austrian general Kray, and would have taken him and his whole army prisoners of war had not peace been declared. Soon after this he died suddenly at Wetzlar, not without suspicion of poison. This suspicion was very generally believed at the time, but nothing has ever transpired to give a colour to it; and it is quite unlikely that if there had been any real grounds for it, it would not, by this time, have been proved beyond a doubt. His death was regarded by his countrymen as a great national calamity; but they only understood the full import of the calamity when, as Napoleon's star rose higher and higher on the ascendant, they found that they had lost the only man in whom that great soldier had to fear an equal.

HOCUS-POCUS, a term applied to conjuror's tricks. According to Turner it was the name of an Anglo-Saxon magician; but others regard the two words as a corruption of the *hoc est corpus* used by priests in the mass.

HOCK-DAY, Hokeday, or Hock-Tuesday, a holiday formerly kept in England on the second Tuesday after Easter to commemorate the expulsion of the Danes in the time of King Ethelred. Along with Michaelmas this festival was at one time used as a term for the payment of rents; and in the accounts of Magdalen College, Oxford, there occur several yearly allowances *pro mulieribus hockantibus. Hocking* consisted in stopping the highway with ropes, and demanding a gratuity from passengers before they were permitted to pass.

HODMAN, a cant term formerly used for a young scholar admitted from Westminster School to be student in Christ Church in Oxford.

HODY, Humphry, an eminent English divine, was born in 1659 at Oldcombe in Somersetshire. In 1676 he entered Wadham College, Oxford, of which he was chosen fellow in 1684, and in which, in after life, he founded ten scholarships to promote the study of Greek and Hebrew. At the age of twenty-one he published his Dissertation against the *History of the Seventy-two Interpreters* by Aristeas. In this production Hody shows that the story told by Aristeas as to the occasion of the Septuagint translation is the invention of some Hellenist Jew; that it is full of blunders and anachronisms; and that it was originally circulated on purpose to recommend the Greek version of the Old Testament. This dissertation was received with much approbation by the learned, excepting Isaac Vossius, who published an angry and scurrilous reply to it in the appendix to his *Observations on Pomponius Mela.* In 1704 Hody published his four books, *De Bibliorum textis originalibus, versionibus Græcis, et Latina Vulgata;* the first containing his dissertation on Aristeas's history, the second treating of the true authors of the Greek version called the Septuagint; the third comprising a history of the Hebrew text, the Septuagint version, and the Latin Vulgate; and the fourth giving an account of the other Greek versions—namely, those of Symmachus, Aquila, and Theodotion, with the *Hexapla* of Origen, and other ancient editions. In 1689 Hody wrote the Prolegomena to the *Chronicle of John Malela,* printed at Oxford; and in 1690 he was made chaplain to Stillingfleet, bishop of Worcester. The deprivation of the nonjuring bishops involved him in a controversy with Mr Dodwell, and gave occasion to a number of polemical pieces, which have long ceased to possess any interest. His support of the ruling party of the church in this controversy recommended him to Tillotson, archbishop of Canterbury, who appointed him his domestic chaplain, an office which he continued to hold under Dr Tenison. In 1698 he was appointed regius professor of Greek in the University of Oxford, and in 1704 he was instituted to the archdeaconry of the same place. Hody died Jan. 20, 1705. He left behind him in manuscript a valuable work, published in 1742 by Dr Jebb, under the title of *De Græcis Illustribus linguæ Græcæ literarumque humaniorum Instauratoribus, eorum vitis, scriptis, et elogiis libri duo.* Prefixed to it is an account in Latin of the author's life, extracted from a manuscript in English left by himself.

HOF, a town of Bavaria, circle of Upper Franconia, on the Saale, 30 miles N.N.E. of Bayreuth. It is surrounded with walls, and has 4 churches, a gymnasium with an extensive library, an orphan asylum and several other charitable institutions. Its manufactures comprise linen, woollen and cotton stuffs, leather, and paper. There are iron mines and marble quarries wrought in the vicinity. Pop., including the two suburbs, about 8000.

HOFER, Andrew, the hero of the Tyrol, was born in 1767 at St Leonard in the valley of Passeyr. Till his forty-second year he had been merely known as an industrious and thriving innkeeper, of great intelligence and probity of character. When the treaty of Presburg transferred the Tyrol from Austria to Bavaria, the Tyrolese had every variety of insult and outrage to endure from the Bavarians and their French allies. The consequence was, that when war again broke out in 1809 between France and Austria, the Tyrolese rose to a man in the cause of the House of Hapsburg; and, putting themselves under the command of Hofer, defeated the allied French and Bavarians in repeated engagements, and at length drove them out of the Tyrol. Till the close of the war Hofer administered the internal government of his native country with much ability and integrity. When the fortune of war again laid Austria prostrate at the feet of Napoleon, the Tyrol was once more made over to the Bavarians; but it was only after the most heroic resistance on the part of the mountaineers that they were able to make good their footing in the country. Hofer was obliged to fly, and a price was set upon his head; but though he contrived to elude the search of his enemies for some time, he was at length taken, January 27, 1810. He was sent to Mantua for trial by court-martial, and was condemned and ordered for execution within twenty-four hours. He died, as he had lived, a hero; and the spot where he fell is still visited by his countrymen as a sacred spot. The Austrian Emperor Francis testified his gratitude to Hofer by ennobling his family, and erecting a splendid monument to his memory in the church of Innspruck.

HOFFMANN, Ernst Theodor Wilhelm, a German writer and artist of brilliant but wild and unregulated genius, was born at Königsberg in Prussia, Jan. 24, 1776. His misfortunes may be considered to have begun in his early childhood, for, when he was a mere infant, his father—a man of talent and high social standing, but of bad temper, and perhaps bad habits—separated himself from his wife, and never again took the least interest in her or any of her children. The charge of Young Hoffmann's education was undertaken by his uncle, a rigid methodical man, who lived by rule and square, and who wasted many hours in trying to train his frolicsome nephew to a clockwork life like his own. At a fitting age he was sent to the public school of Königsberg, where he displayed little aptitude for the classics, but much for music and drawing. From the school he passed to the university, where he listened to the lectures of Kant without understanding or profiting by them. Yet he wrought hard at his law studies, occupying his spare time in giving lessons in his favourite arts of music and drawing; and, after graduation, was appointed assessor of the court of Posen. In the gay society of this town, where his time was only half-occupied, he contracted those habits of dissipation which afterwards brought about his ruin. The abundant field for satire tempted him to use too freely that dangerous gift, and he found it convenient to retire for a time to Plozk, which, two years later, he was allowed to exchange for Warsaw. In the Polish capital he turned to profitable account his taste for music, and was beginning to prosper in the world, when the arrival of Napoleon and his legions once more threw him upon his wits. Failing in his attempt to support himself by any of the forms of art of which he was master, he became a stage director; and, when that resource failed, a miscellaneous writer. It was now that he began that series of essays after collected and published under the title of *Fantasie-Stücke in Callot's Manier* (Fancy-Pieces in the manner of Jacques Callot). The brilliancy and originality of these fancy pieces, which turned chiefly on music, soon made Hoffmann's name known, and procured him abundance of literary and other employment; but his life was still uncertain and chequered by the strangest vicissitudes, arising out of the French war, which in these years was devastating Germany. When peace was restored to that country on the overthrow of Napoleon, Hoffmann was reinstated in his legal appointments, and soon after published his *Elixiere des Teufels,* a two-volume novel, which enhanced his rapidly growing fame. But his success turned his head. He had always been vain, and now he became transcendently so; and as he had no sympathy with the dull conventions of society, he made himself a host of enemies by fierce and frequent defiance of them. In disgust he retired to the wine-house, where, in the company of outcasts like himself, he sought to drown his cares in the wildest orgies. "Strangers," says his most eloquent biographer, "came to Berlin to see him in the tavern. The tavern was his study, his pulpit, and his throne. Here his wit flashed and flamed like an *aurora borealis*, and the table was forever in a roar; and thus, amid tobacco smoke and over coarse earthly liquor, was Hoffmann wasting faculties which might have seasoned the nectar of the gods." In 1817 he published his *Nacht-Stücke* (Night-Pieces); and between 1819 and 1821, his *Serapions-Brüder*, comprising most of his minor tales and fugitive pieces. In 1820 and the following year appeared his *Lebens-Aussichten des Kater Murr* (Tom-Cat Murr's Philosophy of Life), his masterpiece, but which he did not live to finish. He died of a sort of paralysis, Jan. 24, 1822.

Hoffmann's natural powers were all but of the highest order, and, had they been under due control and guidance, might have done great things. He thought he had found his sphere in the poetry of art, which he loved with a deep though hardly with a pure love, as a source of refined enjoyment rather than as a fountain of beauty. Failing to find in it the heavenly peace which he longed for, he prostituted it to the purposes of an earthly excitement. Hence it is that his philosophy degenerates into bombast, and his magnanimity into levity; and his character equally with his writings became tawdry, false, and theatrical. His humour and his fancy, naturally racy and rich, became forced and grotesque; and all his other fine gifts were stultified besides by the incredible rapidity with which, for the most part, he was compelled to write. See Hoffmann's *Life and Remains*, published shortly after his death; and Carlyle's *Miscellanies*, vol. iii., p. 362.

HOFFMANN, *Frederick*, a celebrated physician of the University of Halle in Saxony, was born in that city in 1660. He received his early education in his native town, and made great progress in the mathematics, to which he partly ascribed the success which followed his medical studies. At the age of fifteen he lost both his father and his mother during the prevalence of an epidemical distemper. In 1680 he established himself at Erfurdt, there to study chemistry under Gaspar Cramer; and the following year he received the degree of doctor of physic at Jena. In 1682 he published an essay *De Cinnabari Antimonii*, which was reprinted at Leyden in 1685, 12mo, and laid the foundation of his reputation as an able chemist, which he afterwards increased by professing chemistry in the schools of Jena. It is to him we are indebted for the preparation known by the name of the Anodyne Liquor of Hoffmann, which is considered still as a useful sedative. Frederick III., Elector of Brandenburg, having founded the university of Halle in 1693, Hoffmann was appointed primarius professor, and alone prepared the statutes of the faculty of medicine. His fame soon spread throughout all Germany, and thence into foreign parts; and several learned bodies, including the academies of Berlin and Petersburg, and the Royal Society of London, enrolled him among their members. During his residence at Halle he divided his time between instruction, practice, and study; but more than once he interrupted his pursuits by visits to the different courts of Germany where his professional successes procured him honours, titles, and rewards. He was solicited by the king of Prussia to fix his residence at Berlin; but he preferred remaining in his native country, where he died on the 12th of November 1742. At the age of sixty Hoffmann undertook his great work entitled *Medicina Rationalis Systematica*, Halle, 1730, in 9 vols. 4to, of which Bruhier d'Ablaincourt has given a translation, under the title of *Médécine Raisonnée d'Hoffmann*, 1739, in 9 vols. 12mo. The same physician has also translated from the Latin of Hoffmann a *Treatise on Fevers*, Paris, 1746, in 3 vols. 12mo; the *Politics of Medicine*, ibid., 1751, in 12mo; and *Observations on the Cure of Gout and Rheumatism*. A complete edition of his works has been published, with a life of the author, under the title of *Hoffmanni Opera omnia Medico-physica cum Supplementis*, Geneva, 1740, 1755, 11 parts, in folio. The writings of Hoffmann contain a great mass of practical matter of considerable value, partly compiled from preceding writers, and partly the result of his own observation; but they are also deformed by trifling remarks, hypothetical conjectures, and frequent prolixity and repetition in the details. As a theorist, his suggestions proved of great importance, and contributed to introduce that revolution in the science of medicine which subsequent observation has extended and confirmed. His doctrine of atony and spasm in the living solid, according to which all internal disorders were referred to some preternatural affection of the nervous system, rather than to the morbid derangements of the fluids, first turned the attention of physicians from the mere mechanical and chemical operations of the body, to those of the primary moving powers of the living system. Hoffmann pursued with considerable ardour the study of practical chemistry, and improved the department of pharmacy by the addition of some mineral preparations. But, upon the whole, his practice was cautious, especially in his latter years; and he trusted much to vegetable simples. "I affirm solemnly," said he, "that, though in my youth I ran much after chemical remedies, yet in my age I became convinced that very few remedies, well selected, and derived from substances in appearance the most worthless, afford more prompt and efficacious relief to the sick than the rarest and most elaborate chemical preparations." (J. B—E.)

HOG. See index to MAMMALIA.

HOGARTH, WILLIAM, the greatest of all satirical painters, was born, according to the most probable conjecture, in 1698, in the parish of St Martin, London. His father (whose name, as written and pronounced in these days, was Hogart) was the son of a Westmoreland yeoman, and had removed to London, where he supported himself by teaching and writing. His circumstances were anything but prosperous. In the words of his son (*Hogarth's Anecdotes of Himself*, ed. 1833)—"My father's pen, like that of many other authors, did not enable him to do more for me than put me in a way of shifting for myself. As I had naturally a good eye and a fondness for drawing, shows of all sorts gave me uncommon pleasure when an infant; and mimicry, common to all children, was remarkable in me. An early access to a neighbouring painter drew my attention from play, and I was at every possible opportunity employed in making drawings. I picked up an acquaintance of the same turn, and soon learned to draw the alphabet with great correctness. My exercises when at school were more remarkable for the ornaments which adorned them than for the exercise itself. In the former I soon found that blockheads with better memories could much surpass me; but for the latter I was particularly distinguished."

At the proper age Hogarth was apprenticed to a silversmith, Ellis Gamble by name; but long before he had served out his time he was heartily tired of carving crests and heraldic devices on silver, and longed to begin engraving on copper. To obtain the requisite knowledge of drawing, he began, immediately on the expiry of his apprenticeship, to attend the lectures of Sir James Thornhill, serjeant-painter to the king, but, if the testimony of Horace Walpole may be believed, without attaining any great excellence in drawing from the life. He says himself, however, that frontispieces to books, such as prints to *Hudibras*, &c., soon brought him into the way; but he complains grievously that he was robbed of the legitimate reward of his labours by the printsellers. "The first plate which I published," he says, called *The Taste of the Town*, in which the reigning follies were lashed, "no sooner began to take a run, than I found copies of it in the print-shops, vending at half-price, while the original prints were returned to me again, and I was thus obliged to sell the plate for whatever these pirates pleased to give me, as there was no place of sale but at their shops." Amid these difficulties he struggled on to his thirtieth year, when he made "a stolen union" with the daughter of Sir James Thornhill, his former teacher. Sir James, a man high in station, refused at first to open his eyes to the genius of his son-in-law, and for two years believed that his daughter had disgraced herself and degraded her family by her marriage. At the end of that period, however, he "became both reconciled and generous to the young couple." Up to the time of his marriage, Hogarth had been, in his own phrase, "a punctual paymaster;" and now, to meet his increased expenditure, he "commenced painter of small Conversation Pieces, from 12 to 15 inches high; which, being a novelty, succeeded for a few years." He eked out his income by painting portraits; and though he always spoke with vehement contempt of this branch of art, his extant pieces show that he might easily have attained eminence in it. Before fairly committing himself to these new walks, he had entertained great hopes of succeeding as a historical painter, and, as he himself says, "painted two Scripture stories—*The Pool of Bethesda* and *The Good Samaritan*, with features 7 feet high." Like Molière, who believed to the day of his death that his true calling was the acting and writing of tragedy, Hogarth persisted to the last in declaring high art as his real vocation. His attempts in that walk were never, in his opinion, appreciated as they deserved; and among his friends his delight was to thump the table and snap his fingers, and say—"Historical painters, be hanged! here's the man that will paint against any of them for a hundred pounds. Correggio's *Sigismunda!* look at Bill Hogarth's *Sigismunda;* look at my altar-piece of St Mary Redcliffe, Bristol; look at my *Paul before Felix*, and see whether I'm not as good as the best of them." On one occasion a Mr Freke had asserted that Greene, the composer, was as great a musician as Handel. "That fellow Freke," remarked Hogarth, "is always shooting his bolt absurdly one way or another. Handel is a giant in music; Greene only a light Florimel kind of composer." "Aye," said the artist's companion, "but Mr Freke declared that you were as good a portrait painter as Vandyke." "There he was right," said Hogarth; "and so, by G—, I am; give me my time, and let me choose my subject." So overweeningly confident was Hogarth of his own powers, and so little did he know of the conditions of historical painting, that he did not even deem a special training at all necessary for success in it. But, whatever his genius for high art, he soon found that, if he devoted himself to it alone, he would starve. Necessity compelled him to revert to that style which he had already begun to strike out for himself, and which, as afterwards perfected by him, led him on to fortune and immortal fame. His oil paintings themselves never sold very well; but he made a point of engraving them all, and from the sale of these engravings he realized a handsome fortune. Here, again, his old enemies, the printsellers, interposed between him and the public, and for a time pirated each plate as it appeared, and intercepted the artist's profits. In 1735 Hogarth sent in a petition to parliament, drawing attention to this flagrant outrage upon justice, and the result was a law securing to the artist a copyright of fourteen years in every plate from the date of publication. In 1753 Hogarth published his *Analysis of Beauty*, in which he endeavours to prove that the foundation of all beauty is a waving line curved somewhat like an S; while a less pronounced curve is the line of grace. This idea, and the curious illustrations brought forward in support of it, drew down upon its propounder's head a perfect shower of pamphlets and criticisms, all hostile, and nearly all sarcastic in their tone. One of the most amusing quarrels that resulted out of this publication was that with Wilkes and Churchill. Both of these persons, formerly Hogarth's friends, joined in the outcry against him—the first in his newspaper (the *North Briton*), the other in his poetical epistle. Hogarth had his revenge. Churchill descends to posterity as a bear hugging a post inscribed with an ascending scale of lies. Of Wilkes' famous portrait, Hogarth himself says—"This renowned patriot's portrait, drawn like as I could as to features, and marked with some indications of his mind, fully answered my purpose. The ridiculous was apparent to every eye! A Brutus! a saviour of his country! with such an aspect, was so arrant a farce, that, though it drew much laughter from the lookers on, galled both him and his adherents to the bone." As Hogarth advanced in years his health began rapidly to give way, but his powers of mind remained unimpaired to the end. He died October 26, 1764, and was buried in the churchyard of Chiswick, near London. His wife, who never bore him any children, survived him for fifteen years, and on her death, in 1789, was buried by his side.

Johnson's famous lines on Hogarth are equally true and pleasing:—

> "The hand of him here torpid lies,
> That drew the essential forms of grace;
> Here closed in death the attentive eyes,
> That saw the manners in the face."

As a man, Hogarth is one of the most interesting and characteristic types of the true English race. Under a somewhat rough exterior lay one of the most generous, open, and honest souls that England had to boast of in all the eighteenth century. Born and brought up in London, from the shadow of whose smoke he hardly ever emerged except for an occasional holiday, he imbibed many of the prejudices and little narrownesses incident to such a mode of life. But in his case, as in Dr Johnson's, the knots and excrescences that disfigured the oak also marked its strength. No man of that century, not the great lexicographer himself, fought a nobler battle against great odds, or gained in the end a nobler victory. As a satirist, Hogarth, like all satirists, had foes numerous and malignant. But, though these often assailed him ungenerously and unjustly, he scorned to take a mean advantage over them, or to glory in his triumph when the scale turned in his favour. The very last sentence in his memorial of himself runs thus:—"This I may safely assert, that in the course of my life I have done my best to make those about me tolerably happy, and my greatest enemy cannot say that I ever did an intentional injury."

To assign Hogarth his rank among painters, is no difficult task. In the class to which he belongs he has had few imitators and no rivals, either in our own or in any other country. Of all English painters, Hogarth's chances of immortality are the best; and it has been well said that our chances of another Hogarth are as precarious as our chances of another Shakspeare. To the student of history his works are invaluable for their complete and sternly truthful pictures of the manners and even the thoughts of the eighteenth century. In the words of Thackeray—"We look, and we see pass before us the England of a hundred years ago. The peer in his drawing-room, the lady of fashion in her apartment, foreign singers surrounding her, and the chamber filled with gew-gaws in the mode of that day; the church, with its quaint florid architecture and singing congregation; the parson with his great wig, and the beadle with his cane; all these are represented before us, and we are sure of the truth of the portrait. We see how the lord mayor dines in state; how the prodigal drinks and sports at the bagnio; how the poor girl beats hemp in Bridewell; how the thief divides his booty and drinks his punch at the night-cellar, and how he finishes his career at the gibbet. We may depend upon the perfect accuracy of these strange and varied portraits of the bye-gone generation. We see one of Walpole's members of parliament chaired after his election, and the lieges celebrating the event, and drinking confusion to the Pretender; we see the grenadiers and trainbands of the city marching out to meet the enemy; and have before us, with sword and firelock, and white Hanoverian horse embroidered on the cap, the very figures of the men who ran away with Johnny Cope, and who conquered at Culloden. The Yorkshire waggon rolls into the inn-yard; the country parson, in his jack-boots and his bands and short cassock, comes trotting into town, and we fancy it is Parson Adams with his sermons in his pocket. The Salisbury fly sets forth from the old Angel; you see the passengers entering the great heavy vehicle up the wooden steps, their hats tied down with handkerchiefs over their faces, and under their arms, sword, hanger, and case-bottle; the landlady, apoplectic with the liquors in her own bar, is tugging at the bell; the hunch-backed postilion (he may have ridden the leaders to Humphrey Clinker) is begging a gratuity; the miser is grumbling at the bill; Jack of the Centurion lies on the top of the clumsy vehicle, with a soldier by his side —it may be Smollet's Jack Hatchway—it has a likeness to Lesmahagow. You see the suburban fair, and the strolling company of actors; the pretty milk-maid singing under the windows of the enraged French musician—it is such a girl as Steele charmingly described in the *Guardian*, a few years before this date, singing under Mr Ironside's window in Shire Lane her pleasant carol of a 'May Morning.' You see noblemen and blacklegs bawling and betting in the Cock-pit; you see Garrick as he was arrayed in *King Richard;* Macheath and Polly in the dresses which they wore when they charmed our ancestors, and when noblemen in blue ribbons sat on the stage and heard their delightful singing. You see the ragged French soldiery in their white coats and cockades at Calais gate; they are of the regiment, very likely, which friend Roderick Random joined before he was rescued by his preserver, Monsieur de Strap, and with whom he fought on the famous day of Dettingen. You see the judges on the bench; the audience laughing in the pit; the student in the Oxford theatre; the citizen in his country walk. You see Broughton, the boxer; Sarah Malcolm, the murdress; Simon Lovat, the traitor; John Wilkes, the demagogue, leering at you with that squint of his which has become historical, and with that face which, ugly as it was, he said he could make as captivating to woman as the face of the handsomest beau in town." These subjects are treated for the most part in the satirical vein; but Hogarth's satire is never an end to itself, it is generally a means towards the teaching of some valuable lesson of practical morality. Sometimes, like Juvenal, the painter dissects with a hideous minuteness the follies and vices of his day, which in various guises are the follies and vices of all time. Like Swift, revelling in the morbid anatomy of the human heart, he sometimes (as in his *Four Stages of Cruelty*) depicts scenes that in themselves shock and repel the observer, but are yet made interesting by their wonderful power and truth to nature; while, on the other hand, he is not surpassed by De Foe himself in the number, homeliness, and graphic force of his details. So great, indeed, is Hogarth in these respects, that the criticism of Charles Lamb becomes literally true when he says that "his graphic representations are indeed *books;* they have the teeming, fruitful, suggestive meaning of words. Other pictures we look at; his prints we read." It was fashionable among some of Hogarth's contemporary critics to settle his claims to posthumous fame by describing him as a *caricaturist*, and by ridiculing the technical execution of his works. On the first head it is only necessary to repeat what has been already said, that "the quantity of thought which he crowds into every picture would almost unvulgarize every subject which he might choose," and that consequently he can scarcely be classed among caricaturists at all, as that term is now understood. On the second head, small wits of the last century were misled by the verdict of Horace Walpole, who said that Hogarth had but little merit as a painter. Posterity, however, has reversed this sentence of the captious critic; and indeed it must be plain to all who have seen Hogarth's pictures that, except in the matter of colouring, their technical merits are not only great, but remarkable. As a draughtsman, indeed, he has been surpassed by many of his countrymen; but his power of composition is such as few English painters have ever shown at all. Even his colouring, which is confessedly his weak point, may be defended to some extent, as having been laid on in dead tints chiefly that the eye of the spectator might not be distracted by gaudy hues from the action and moral of the various pieces; yet there are many individual pieces of painting in Hogarth's pictures which show that, if he had not had special reasons for persevering in the style he originally adopted, he might have ranked high among English colourists. This much, however, is certain, that, whatever Hogarth's technical merits or defects may be, so long as man shall continue to be man's proper study, so long will Hogarth's pictures, in virtue of the human interest they possess, continue to find students and admirers.

(Hogarth's *Memoirs of Himself;* Allan Cunningham's *Life;* Ireland's *Life;* Hogarth's *Works*, by Nichols and Steevens; Charles Lamb's *Essay on Hogarth;* Thackeray's *Lectures on the English Humorists;* Walpole's *Anecdotes;* and Waagen's *Arts and Artists of England*, where an able and elaborate defence and analysis of Hogarth will be found.)

HOGG, JAMES, a Scottish poet and miscellaneous writer, best known by his pastoral and poetical title of the *Ettrick Shepherd.* He was born in the humble rank of a shepherd, and his early lot was full of hardship, but his situation had its redeeming and compensatory features. He was not, like Burns, condemned to severe and irksome labour, forced to do the work of a man when a mere stripling. He had not, like Bloomfield or Gifford, to undergo the close, monotonous, and depressing confinement of a workshop. He had the free range of the mountain and glen in a picturesque district famous for its historical and poetic associations, and he was familiar from infancy with the heroic and legendary lore and ballad strains of the Border. When his great contemporary Scott wondered at his untaught minstrelsy, the Shepherd could say—

> "He little weened a parent's tongue
> Such strains had o'er my cradle sung."

By the maternal side Hogg was descended from a long line of shepherds, noted for their fidelity, skill, and devoted attachment to their masters. His mother, Margaret Laidlaw, was a great collector and reciter of ancient ballads and Border history, and a woman of remarkable liveliness, humour, and spirit. Her cottage was the favourite resort of all the young shepherds of Ettrick and Yarrow. His father, Robert Hogg, was, mentally and morally, a much inferior person. He had also been a shepherd, but he subsequently embarked in the business of a store-farmer and drover, frequenting the English and Scotch markets, and he soon wrecked the humble fortunes and prospects of the family. James was the second of four sons, born in a cottage at Ettrick Hall, near the parish church and school. In the various accounts of his own life which he wrote from time to time, Hogg gave 1772 as the year of his birth. At first he said he was born in the latter end of that year, but subsequently he claimed to be born on the anniversary of Burns' birth-day, the 25th of January. The parish register, however, records his baptism as having taken place on the 9th of December 1770. About seven years after this time Robert Hogg's affairs became desperate, his effects were sold, and in the distress and poverty of the family James was put out to service in the neighbourhood as a cow-herd, which he considered to be the lowest and worst occupation in that part of the country. It is, however, the usual commencement of the life of an ordinary shepherd until he has attained his fifteenth or sixteenth year, when he is considered fit to be trusted with a *hirsel* or flock of sheep. Previous to entering upon service, Hogg had attended the parish school, and was, as he tells us, at the head of a class of young scholars, who read the Shorter Catechism and Proverbs of Solomon. This could hardly have been attained in less than a twelvemonth, and in the following year he was placed by his parents for four months under a private teacher, with whom he was instructed in the Bible, and learned to write imperfectly. The Shepherd's statements as to the amount of his school education are vague and contradictory. In one he says that the whole did not cost ten shillings; in another, that he was about six months at school; and in a third (his farewell address to the readers of the *Spy*) he boldly affirms that he was never at school. The probability is that he had the same amount of education as other children in the district of the same age, but that from his lively rambling disposition and love of out-door sports, he was a careless and irregular scholar. In his fourteenth year he had saved five shillings, with which he bought an old violin, on which he practised at nights in the stables and cow-houses where he was forced to make his bed. He had access to few books, he says, except theological works, until, in his eighteenth year, he got a perusal of the *Metrical History of Wallace*, and Ramsay's *Gentle Shepherd* (which he wished had been in prose or in the metre of the Psalms), and Burnet's *Theory of the Earth*, which he says had nearly overturned his brain. Chance newspapers also fell in his way, which he read through, but was often "no wiser than when he began." In attempting to write he found he had forgotten several of the letters, and had to copy them from a printed book, or "patch up the words in the best way he could without them." This picture of intellectual stagnation on the part of one afterwards remarkable for mental activity and ambition, and happening in the midst of a body of intelligent shepherds and farmers, who were all readers, as he relates, and delighting in poetry and music, has been pronounced incredible. It is clearly exaggerated, but Hogg's genius was slow in manifesting itself; his fancy flowered late. Favourable circumstances, however, were now at hand. After serving a number of masters, first as cow-herd and afterwards as shepherd, he was engaged in the latter capacity by Mr Laidlaw, tenant of Blackhouse, a farm on the Douglas Burn, in Yarrow. From Whitsunday 1790 to Whitsunday 1799, Hogg continued in the service of Mr Laidlaw. He was treated with affectionate kindness, and had the use of a considerable collection of books, which he soon exhausted, and then subscribed to a circulating library in Peebles. About the year 1793 he obtained a glimpse of the wilder scenery of the West Highlands, being despatched by his master with a flock of sheep to the head of Strathfillan, in Perthshire. This period of nine years, from his twentieth to his twenty-ninth year, was perhaps the happiest of Hogg's life. He was buoyant and vigorous, the envy of the shepherds for his swiftness and agility, and the delight of the country maidens for his gay fancy, music, and handsome appearance. He soon added the recommendation of being a poet. Two months in every year formed a sort of poetical carnival in his shepherd's life. From the middle of July to the middle of September his only duty was what was called "summering the lambs." The young flock was committed to his care, and all he had to do was to move them from place to place. There was no toil or fatigue in the occupation, his dog may be said to have done the whole; and, carrying his books with him, the Shepherd had ample leisure among the green hills and quiet waters for study and contemplation. In the little library at Blackhouse were the *Spectator*, the works of Milton, Pope, Thomson, and Young, with some books of travels and treatises of "sound divines," all of which, with others, Hogg eagerly perused. He may be said to have made the whole circle of standard English literature, and he was not without worthy and congenial associates. His own brother William was a man of strong sense and literary tastes, who contributed to several periodicals; another shepherd, Alexander Laidlaw, was equally accomplished in his humble sphere; and the eldest son of his master was that Mr William Laidlaw afterwards known as the confidential friend and manager of Sir Walter Scott at Abbotsford, the author of the beautiful ballad of *Lucy's Flittin'*, and in all respects a most amiable, ingenious, and accomplished man. Laidlaw was ten years younger than Hogg, but their acquaintance soon ripened into a tender friendship, and Laidlaw seized every opportunity of bringing forward the talents of his friend, and aiding in their development. The first dawnings of such a mind, and the successive steps by which the poet overcame the difficulties of his situation would, if faithfully narrated, form an interesting record. Burns has told us how love and poetry began with him in his early obscurity; and Hogg's first attempts consisted of songs and ballads to be sung by the country girls in chorus. "The first time," he says, "that I attempted to write verses was in the spring of the year 1796—the first time I ever heard of Burns was in 1797, the year after he died." A man recited to him *Tam O'Shanter*. "This," he adds, "formed a new epoch of my life. Every day I pondered on the genius and fate of Burns. I wept, and always thought with myself—what is to hinder me from succeeding Burns. I, too, was *born on the 25th of January*, and I have much more time to read and compose than any ploughman could have, and can sing more old songs than ever ploughman could in the world. But then I wept again because I could not write." The poet's memory, or his desire to appear a poetical prodigy, the "last infirmity" of literary ambition, has here completely misled him. He had written and published verses, and imitated Burns, three years before 1797. His first printed piece was a short tale in the measure and style of Burns's *Holy Fair*, entitled *The Mistakes of a Night*. It is a coarse but humorous effusion of eleven stanzas, and was printed in the *Scots Magazine* for October 1794, with a note appended to it calculated to sober the vanity of the writer. The editor said he was disposed to give the verses a place, to "encourage a young poet," who, he hoped, *would improve*, and be at more pains to "make his rhymes answer," and to "attend to grammatical accuracy."

After quitting Blackhouse, Hogg removed to Ettrick, to a small farm rented by his brother William, who had married and resigned the lease of the farm in favour of the poet and his father. He looked about for some more promising situation as overseer or manager; and in June 1800 took a tour to the Highlands, proceeding to the sources of the Dee. To William Laidlaw he wrote from Blairgowrie, "I must enter amongst the bens and glens of the Grampians —these sovereigns of the north I see towering their ancient tops, specked with the snows of the last century, and aspiring to bid 'good morrow' to the sun." On his return he committed what he afterwards considered—and justly considered—a great folly. He had gone to Edinburgh market, he says, and whilst waiting there from Monday to Wednesday, he suddenly resolved on writing out some of his poems from memory, and having them printed. The volume appeared in January 1801, and was entitled *Scots Pastorals, Poems, Songs, &c., mostly written in the dialect of the south, by James Hogg, tenant in Ettrick.* In one of his autobiographies Hogg says this volume was full of errors and imperfections; he had left the manuscript with the printer (one Taylor, in the Grassmarket), and seen no more of his poems until he received word that a thousand copies were thrown off. This must not be taken literally. He had seen the proof sheets, but he was soon ashamed of the publication, which produced nothing but mortification. His friends in the Forest complained that he had styled himself a tenant in Ettrick, the farm being really held by his brother; but he replied that he had given no such order, and that in the proof sheet which he received to which the title-page was annexed, there was no such designation. In one of the pieces he had reflected on Lord Napier, an extensive proprietor in Ettrick. "I see my error," he writes to Laidlaw, "but what ailed both you and Clarkson, who had both perused the MS., that you had not told me that sooner? It is madness to talk of losing the whole impression; to do that, you know, is entirely out of my power; *I wish I had the one paid that is printed*, and other things which are more pressing at present. It is a great mortification to my gay heart, which fondly imagined the whole world were my friends; d—n it, I'll proceed no farther with this reflection." And then the poor bard changes his tone, and alludes jocularly to the chance of Lord Napier sending him a challenge! He, the Shepherd, as the party challenged, would, of course, have the choice of distance and weapons; and he would select one of his lordship's hill sides in Ettrick; his weapon would be fragments of rock, and hurling these down on the peer, he would make him for once a *fugæ*. Such was Hogg on his first publication—rash, blundering, and improvident—and such he continued to the last.

In the autumn of 1802, Sir Walter, then Mr Scott, "the Shirra," made a raid into Yarrow for the purpose of collecting materials for a third volume of the *Minstrelsy of the Scottish Border*. He was accompanied by John Leyden, and he carried an introduction from another poetical Borderer, Andrew Mercer, to William Laidlaw at Blackhouse. Laidlaw had received from Hogg a copy of an ancient ballad, called *Auld Maitland*, which the Shepherd had written down from the recitation of his mother and uncle—the latter a shrewd old shepherd named "Will of Phawhope." The relic was deemed invaluable; and Scott, before he left the district, took a note of Hogg's address that he might correspond with him. The Shepherd was then absent in the north. Affairs had gone ill at Ettrick, and he had tried another journey to see if anything could be done in the Highlands "in the farming line," but returned unsuccessful.

Scott never lost sight of his poetical brother in the Forest. He corresponded with him, and becoming more and more curious to meet with one who had interested him so strongly, he made another visit to Blackhouse, with the intention of getting Mr William Laidlaw to guide him to Ettrick. They went by Dryhope and St Mary's Loch over the high green solitary hills that separate the head of Yarrow from her sister stream; and arriving in the valley of Ettrick put up their horses at Ramsay-cleuch, a farm occupied by some relatives of Laidlaw. A cordial welcome and a Dandie Dinmont dinner awaited the Sheriff and his friend, and in the evening Hogg was sent for to *come to tea*. "For at that time," says Laidlaw, "the good Shepherd retained all his original simplicity of character, and he brought with him a MS. of some size—enough at least to show his industry—filled with ballads and fragments. Mr Scott's meeting with Hogg was like that of an elder brother meeting a younger that he had not seen for years, and whose talents and acquirements were far beyond his hopes and expectations." The incident formed a grand era in the history of the Shepherd. Scott became his model as a poet, his judicious counsellor, and his indefatigable friend. No outbreaks of waywardness, caprice, or jealousy on the part of the irritable and impulsive bard of Ettrick, could damp the zeal or lessen the generosity of his first and greatest patron.

Hogg made two more Highland expeditions, of which he published some account in a series of letters in the *Scots Magazine*. The narrative shows considerable facility in prose composition, with touches of poetical feeling; but his attention was chiefly directed to the rural economy of the north. One of these tours was extended to the Hebrides, which he thought highly favourable for the extension of sheep farming, though then chiefly occupied in the rearing of black cattle. He got a neighbour in Ettrick to join him in taking a farm in the Island of Harris; lambs were purchased for stocking the farm in the summer of 1804; the poet had written his *Farewell to Ettrick*, and both parties had set off for Harris, when he learned, he says, about the middle of July, that he could not enter into possession—"that the tacksman's right to the subject was called in question, and a plea entered at the Court of Session accordingly." He gave up all intention of proceeding to the island, and went off to the north of England, among the lakes of Cumberland, for some time, "in order to avoid a great many disagreeable questions and explanations." His friend, the Ettrick farmer, who had proceeded with his stock part of the way, was a considerable loser by the poet's mismanagement; and Hogg says that he himself "lost all the money he had made by a regular and industrious life." He had saved about L.200 while a shepherd at Blackhouse. The affair altogether was supposed to leave a stain on the poet's moral character as well as sagacity; and it was long ere he regained the countenance or regard of his early friends in the Forest. He did not rejoin them at this time, but engaged himself as a shepherd in Nithsdale.

The second publication of Hogg was made in 1807. He had corresponded with Scott, and was encouraged by him to collect and publish a volume of legendary ballads and songs under the title of the *Mountain Bard*. The poems evinced decided talent; Scott heralded the volume with a brief but kind prefatory notice; the Shepherd told the story of his life and misfortunes, and public interest being thus excited, the work was well received. By its sale, and by a *Treatise on the Diseases on Sheep*, published the same year, he realized about L.300. With this money the Shepherd unfortunately embarked in farming in Dumfries-shire, and in three years was utterly ruined, abandoning all his effects to his creditors. He returned to Ettrick, and there found only cold and estranged looks. He could not even obtain employment as a shepherd; so, wrapping his plaid around him, he set off, in February 1810, to push his fortune in Edinburgh as a literary adventurer.

No vicissitude could abate Hogg's self-reliance, or diminish what he honestly called his vanity. He would have fared ill, however, but for a generous Border admirer, Mr John Grieve, established in business in Edinburgh, who opened his house to him as Thrale did to Johnson, and for years suffered him to want for nothing. From the noble family of Buccleuch he seems also to have received assistance. In 1810 he published a collection of songs, which being dedicated to the Countess of Dalkeith, and recommended to her notice by Scott, was rewarded with a present of a hundred guineas. He then commenced a weekly periodical, *The Spy*, which he continued from the 1st of September 1810 to the 17th of August 1811. Several friends contributed essays to this work, but its general strain was coarse and indelicate. His poetical genius had in the meantime been gradually purifying itself, and his *Queen's Wake*, published in 1813, established his reputation as one of the first poets of the age. This was followed by *Mador of the Moor*, a Highland story in the Spenserian stanza, of improbable plot, but highly effective in its descriptive scenes. He next published *The Pilgrims of the Sun*, a wild mystical poem in blank verse; and *The Poetic Mirror*, a successful imitation of the style of some of the living poets. This work was aided by contributions from poetical friends.

Scott had been applied to, but refused in a curt and decided letter, which gave such offence to the now elated Shepherd, that he replied to him in wrath, addressing him as "D—d sir," "yours in disgust," &c. For this atrocity he afterwards apologized, and Scott bade him "think no more of the business, and come to breakfast next morning." The Duchess of Buccleuch, on her deathbed in 1814, had made a request of the Duke that he would do something for the Ettrick bard, and the Duke gave him a lease for life of the farm of Altrive in Yarrow, consisting of about seventy acres of moorland, on which the poet built a house and spent the last years of his life. He took possession of it in 1817, but his literary exertions were never relaxed. Before 1820 he had written *The Brownie of Bodsbeck*, a tale of the Covenanters, and two volumes of *Winter Evening Tales*, besides collecting, editing, and writing part of two volumes of *Jacobite Relics*, and contributing largely to *Blackwood's Magazine.* In 1820 he married an amiable lady of a good Annandale family, and found himself possessed of about L.1000, a good house, and a well-stocked farm. Fortune seemed at last to be propitious—he was the most prosperous as he was the most celebrated man in the Forest. So intent was he on his home felicity, and his reputation as a store-farmer in Yarrow, that he declined a flattering invitation from Sir Walter Scott to accompany him to London to witness the coronation of George IV. The Shepherd preferred attending the great sheep fair at St Boswell's! This new-born virtue of prudence, however, soon forsook him; he became a candidate for a large farm on the Buccleuch estate. On the 29th of November 1821 he wrote to Laidlaw, "The farms will be decided to-day, and we will soon see what has been allotted to me. I have made no movement one way or another; no doubt I could have Mount Benger for the asking, but I did not know whether it was to be lowered or not, and had hopes that they might have some better one in their eye for me." Mount Benger was to be his destiny. It adjoined Altrive, and he took it on lease for nine years. He stocked it and conducted it expensively, as his neighbours alleged—having double the number of horses that was required, and treble the number of work-people. His hospitality was also profuse. To meet his new engagements he wrote several novels, republished his poems, and gave to the world a second metrical romance, *Queen Hynde*, which contains many fine passages, but is deficient in poetical colouring and interest. He had realized nearly L.1000 by these various literary labours.

Hogg's connection with *Blackwood's Magazine* kept him still more familiarly before the public. The wit and mischief of some of his literary friends made free with his name, and represented him in ludicrous and grotesque aspects, but the effect of the whole was favourable to his popularity. His appearances in the *Noctes Ambrosianæ* gave an erroneous impression of his habits, and so far prejudiced him in the estimation of the graver portion of his friends and the public, but they unquestionably elevated his reputation as a man of genius and of rare colloquial powers. For some time he winced keenly under the monthly infliction, but at length came to relish the poetical exaggeration of his friend Wilson, and predicted that the magazine would sink whenever his name was withdrawn from it. For much of the *éclat* and brilliancy of his latter years, relieving and gilding days of adversity, he was indebted to these celebrated and unique dialogues.[1] By the end of his nine years' lease of Mount Benger the poet was again a ruined man. He made a visit to London in the winter of 1831, and was fêted and feasted by the nobility, literati, and public men of the metropolis. He was engaged to banquets weeks in advance, and often engaged to three places in one day. On his return a public dinner was given him in Peebles—Professor Wilson in the chair—and he acknowledged that he had at last "found fame." His health, however, was seriously impaired. In November 1833 he writes to a private friend, "Though plump and fair, I am plagued with an asthmatic cough and *wheezing* which renders me quite useless, and disables me from hunting, fishing, &c., without which you know I cannot subsist." In the same letter he mentions that his domestic memoir of Sir Walter Scott had been published in Albany—its circulation being confined (which, of course, was found impossible) to the United States. "I had an offer for it," he remarks, "which I did not find myself in circumstances to refuse." The publication of this *brochure* drew down upon Hogg the keen resentment of Mr Lockhart. It is, however, a candid and just representation of his illustrious friend; though, like all Hogg's reminiscences, it is confused and inaccurate in details. With his pen in his hand to the last, the Shepherd in 1834 published a volume of *Lay Sermons;* and in 1835 two volumes of *Montrose Tales.* By the latter end of this year his illness assumed the form of dropsy, and after a short confinement, and three days of calm and motionless insensibility, he died on the 21st of November, having nearly completed his sixty-fifth year. He was buried in his native churchyard of Ettrick. Wordsworth and many lesser bards mourned his death; and among his own hills and dales the loss was felt to be great and irreparable. His fame seemed to fill the whole district, and was brightest at its close; his presence was associated with all the Border sports and festivities, and as a man James Hogg was ever frank, joyous, kind, and charitable.

---

[1] Before the commencement of the *Noctes*, letters, poems, &c., were printed in *Blackwood* in Hogg's name, which he never wrote, and which wanted the geniality and humour of Wilson's personations; of these he complained grievously. The following is part of an unpublished letter, addressed to Sir Walter Scott, and dated "Altrive Lake, October 3, 1821:"—

"My dear Sir Walter,—Like every other vassal, whose situation with his chief is perfectly understood, though never once mentioned, I always sit wisely still, unless either called upon by you to some great weaponshaw; or when I find marauders and freebooters encroaching on my own privileges. In this last case I am never behind, viz., in asking indemnities, although in the former one (as in the late coronation affair) I sometimes show a little obstinacy to budge. I am fairly in Jamie Telfer's situation, and therefore I come lang eight miles barefoot to Abbot's Ha' in hopes to have a rise in my favour. I allude to the beastly usage of me by Blackwood, and some new cronies of his. I know not what to do with that wretch. He will neither answer a letter nor regard me one way or another; and though I have a written promise, dated nineteen months back, 'that my name should never be mentioned in this way without my own consent,' yet you see how it is kept, and how I am again misrepresented to the world. I am neither a drunkard, nor an idiot, nor a monster of nature, nor am I so imbecile as never to have written a word of grammar in my life. I would not mind their vulgar injurious ribaldry so much on my own account, but there are other feelings now that I am bound to regard above my own, where the wounds inflicted by such assassins rankle with so keen a smart, that I am unable to allay them, and this part of the business I cannot endure. I am assailed by letters from every quarter, urging me to do something in my own defence, which I am very willing to do if I wist what to do; but I am so apt to run wrong that I dare not trust myself without asking your advice. Shall I answer him in print—pursue him at law (to which it will soon come if I answer him)—or knock out his brains? I must do something, for I am told there never was a man so ill-used in Britain; and truly I do not think there ever was. . . . . Will you suffer your liege yeoman to be guided this way, and advise him to take all patiently? You were angry at me the last time I went to law, and, as a small arlepenny, made me pay the piper damnably; and though I am burning for a mischief again, I shall [not] be free of entering on it this time without advice. Now, dear Sir Walter, though I have written this in bed for sheer amusement, I want a serious line from you what you think on the subject. I am lying sick of the measles, and not like to get readily free of the distemper, else I would have been down seeing Laidlaw, Lockhart, and yourself this week, which has for several years been the one I always paid my yearly homage. Yours, ever most affectionately, James Hogg."

We have left out some remarks by Hogg about Blackwood and pecuniary affairs. He quarrelled with most of his publishers, and generally had the wrong side of the quarrel. About a year after the date of the above letter, Professor Wilson commenced his *Noctes*—the Shepherd being the prime interlocutor; they were continued till 1832, then stopt for two years, and resumed in 1834, by the voluntary act (as appears from Mr Rogers' *Modern Minstrel*) of Professor Wilson, who remitted to the Shepherd a *solatium* of five guineas a sheet.

The collected works of this self-taught genius and remarkable man are comprised in eleven volumes—five of poetry and six of prose. His tales are more popular in America than in this country. They contain true and affecting transcripts of nature, but often run into exaggeration, coarseness, and indelicacy. His *Shepherd's Calendar* is the best of his prose works, and must always be interesting for its genuine representation of pastoral life. His shepherds and shepherds' dogs are as faithfully delineated and as distinctly marked as those on the canvas of Landseer. As a poet Hogg is not only the best imitator of Scott, but has a vein of wild imagination peculiarly original. Nothing can be more exquisite than some of his lyrics and minor poems—his *Skylark; When the Kye Comes Hame;* his verses on the *Comet* and *Evening Star;* and his *Address to Lady Ann Scott*, the last combining the most beautiful and touching description of cottage life among the solitary hills, with a certain solemnity of feudal homage and religious feeling tinged with the lights of a poetical superstition. The *Queen's Wake* unites his characteristic excellences—his command of the old romantic ballad style, his graceful fairy mythology, and his aerial flights of imagination. The story of Kilmeny stands by universal consent at the head of all our fairy tales: it is inimitable for its scenes of visionary splendour, purity, and bliss, linked to the fairest objects of earthly interest, sympathy, and affection. In such compositions Hogg seems completely transformed; he is absorbed in the ideal and supernatural, and might have claimed, over all his contemporaries, the Delphic laurel for direct and immediate inspiration. (R. C—S.)

HOGSHEAD, a measure of capacity, containing 63 old wine gallons, or 52½ imperial gallons. The English hogshead was 51 gallons; but the London hogshead of beer was 3 gallons more, and of ale 3 gallons less. All these measures, however, are now superseded.

HOGUE, or HAGUE, CAPE DE LA, a bold headland of France, forming the N.W. extremity of the department of Manche, 16 miles N. by W. of Cherbourg. Off this point the combined English and Dutch fleets defeated the French 22d May, 1692.

HOHENLINDEN, a village of Bavaria, circle of Upper Bavaria, 18 miles E. of Munich, celebrated for a victory gained by the French and Bavarians over the Austrians, 3d December, 1800.

HOHENZOLLERN-HECHINGEN and HOHENZOLLERN-SIGMARINGEN were two sovereign principalities of Germany, of which the capitals were Hechingen and Sigmaringen. The territories are contiguous, and are completely inclosed by Wirtemberg and Baden. H.-Hechingen, the more northern of the two, has an area of 116 square miles, and contained in 1850, 20,471 inhabitants. H.-Sigmaringen has an area of 433 square miles, and in 1850 had 41,141 inhabitants. By treaty of 7th December, 1849, the reigning princes ceded all sovereign rights over their respective principalities to the king of Prussia, in return for the payment to the prince of H.-Hechingen of an annual rent of 10,000 thalers (L.1450), and of half that sum to his legitimate heir; and to the prince of H.-Sigmaringen, and his heirs in succession, of an annual rent of 25,000 thalers (L.3750), the princes still retaining possession of their estates. By a family compact, dated 3d February, 1850, and executed 10th May, 1850, the prince of H.-Hechingen made over all his hereditary possessions to Prince Antony of H.-Sigmaringen. By royal decree of 20th March, 1850, the title of highness was conferred on the two princes, with the prerogatives of younger princes of the royal house.

HOLBACH, PAUL THYRY, BARON D', a French *philosophe* of the eighteenth century, was born in 1723 at Heidelsheim, in the Palatinate. He was brought up in Paris, spent the greater part of his life in that city, and died there in 1789. His name has been saved from oblivion more from his connection with the French encyclopædists, and his judicious patronage of rising literary merit, than from the intrinsic merit of his own works, though these are very numerous. His house in Paris was the rendezvous of those spirits whom Mme. Geoffrin had found too daring to receive at her philosophical dinners, and for forty years was the centre and hot-bed of the new philosophy of which Diderot, Helvetius, and Grimm were the chief apostles. D'Holbach was a man of considerable means, of which, he expended no small part on the pleasures of the table; and it was believed that the good cheer of the baron's board was quite as attractive to his guests as his own conversation. The baron himself was a freethinker of the lowest type, and as much an atheist as a man can be. Like most persons of that stamp he was superstitious, and as credulous as a child. His materialism was of so gross a kind that some of the finer spirits of the age eschewed his society altogether. The discreet D'Alembert shunned him; Buffon maintained a haughty reserve; and J. J. Rousseau openly quarrelled with him. Much interesting gossip about the baron and his connection with the new opinions is to be found in Grimm's *Correspondence.* Besides contributing largely to Diderot's *Encyclopédie*, D'Holbach wrote a *Système de la Nature*, which Voltaire condemned, and with good reason, as "bad in diction, absurd in philosophy, and execrable in morals." The work is indeed villainous in its purport, and one of the most unblushing and flagrant attacks ever made on morality; but it is so excessively pointless, diffuse, and ill-argued as to be comparatively harmless. Still worse, if possible, is his *Christianisme Dévoilé* (Christianity unmasked), the object and the ultimate fate of which were nearly the same as those of the work already mentioned. All these works are now happily forgotten.

HOLBEACH, a market-town of Lincolnshire, 37 miles S.S.E. of Lincoln. The church is a large and beautiful structure, with a tower surmounted by an elegant octagonal spire. It has a well-endowed free grammar school, an hospital for fourteen poor old men, and a public library and news-room. The inhabitants are chiefly engaged in agriculture, the land in the neighbourhood being very fertile. Market-day, Thursday. Pop. (1851) 2245.

HOLBEIN, HANS or JOHN, the greatest of the old German masters after Albert Dürer, is generally described as a native of Basle. The fact, however, is that neither the place nor the date of his birth is known with certainty. The people of Augsburg claim him as their townsman, as do also, and on better grounds, those of Grünstadt. The common accounts assign his birth to the year 1498; recent researches place it three years earlier. His father was an artist of some note, but his fame was soon lost in that of his son. While studying at Basle, Holbein made acquaintance with Erasmus, of whom he painted many portraits, and who often seriously warned him against the consequences of his fondness for drinking and low company. By the advice of this monitor he removed to England, where his introduction to Sir Thomas More opened up to him the path of wealth and fame. For three years this generous patron entertained him in his house, and at the end of that period introduced him to the king, Henry VIII., who took the artist into his service, and made it a fashion among his courtiers and great nobles to have their portraits taken by his hand. The demands on Holbein's time were soon so great that he had to abandon altogether the higher branches of his art, for which he had discovered a decided genius before leaving Switzerland. His historical pieces are consequently very few in number, but his portraits bear so decidedly the imprint of genius that his name still ranks high among the best portrait-painters of the world. Holbein died at London of the plague in 1554.

Holbein was one of the few artists on record who used his left hand in painting. His extensive practice enabled him to excel pre-eminently in portraits; but he painted with equal ease in fresco, water-colours, and miniature; and his boundless fancy showed itself in the countless designs which he drew for statuaries, engravers, and goldsmiths. It is not fair to judge of Holbein's merits by the pieces which pass in thousands under his name in England. His masterpieces, which are chiefly confined to that country, are known to have been multiplied in copies of every degree of merit, and these copies are frequently palmed off on the picture-fancier as originals. A genuine Holbein ought to be characterized by a very bold relief, the most exquisite finish, the highest clearness and delicacy of tone, and a remarkable force of conception. A selection of his portraits, to the number of 84, was engraved and published by Bartolozzi, in London, 1792–1800, with biographical notes by John Chamberlain. The well-known work entitled the *Dance of Death*, which passes under Holbein's name, is not his at all, though it is true that he drew a series of designs on this subject, which are now in St Petersburg.

HOLBERG, Baron Ludwig, the father of modern Danish literature, was born at Bergen, Nov. 6, 1684. He was born of poor parents, and had long to struggle against poverty. His father, indeed, rose to be a colonel, but he rose from the ranks, and died while his son was but a child. Young Holberg was at first destined for the army, but he preferred study. Having studied theology at Copenhagen, he became successively tutor in several families. We find him teaching French at Christiansand, to which he had proceeded after being attacked by fever in Holland. Shortly after this he made his way to Oxford, where he remained fifteen months teaching music and studying history. Having obtained the tutorship of a family of some importance at Copenhagen, Holberg next visited Germany in company with his charge. After visiting Rome he returned to Denmark. Here he was appointed successively to the chairs of metaphysics and eloquence. Hitherto his life had been one of considerable hardship, but now ease, emolument, and fame, were in his path. In his own interesting account of himself, he mentions that it was not till he was upwards of thirty years of age that he was suddenly seized with the desire of composing in verse. In a short while his *Peder Paars* appeared, and was received with great applause. A national theatre was now founded in Copenhagen, for which Holberg wrote extensively. But the theatricals patronized by Frederick IV. were discouraged by Christian VI. Holberg accordingly turned his attention from comedy to history. Here also he excelled. He wrote the *History and Geography of the Danish Monarchy*; *Ecclesiastical History*; and *Jewish History*. His brethren in the university, who had looked upon the effusions of his comic muse as beneath the dignity of a professor, were now proud of him. He was made rector and treasurer in 1735 and 1737 successively. In 1746 Christian VI. died, and Holberg was henceforth free to devote himself to comedy, which, indeed, he had never altogether lost sight of.

He wrote upwards of 30 comedies. The *Pewterer* was a burlesque on the eagerness of political tradesmen for trying their skill in government on the strength of having read a few pamphlets. It was received with great applause; and has been frequently imitated as well as translated. *The Idle Business, or the Man who has no Time*, is considered by the Danes to be Holberg's masterpiece. He is supposed to have taken the idea of the piece from an English comedy called *The Busy Body*. His piece called *Honourable Ambition* is regarded as very nearly placing the author on a par with Molière. Having travelled in Holland, Germany, France, and Italy, as well as having risen from poverty to high station, Holberg had large experience of men and manners, which he turned to good account. His imagination was rich and original, his estimate of character accurate, his humour always diverting, and the management of his plots ingenious. His expressions, however, are at times coarse, he occasionally exhibits carelessness in minutiæ, and renders his burlesque sometimes extravagant.

Besides comedy and history, he wrote poems. *Peder Paars* has been already noticed. *The Subterranean Journey of Nicolas Klim* has been translated into most European languages, and although a satirical piece, it is said to have been gravely quoted as history by a German naturalist. The revenue which arose from his writings was very considerable. Though he lived frugally, he was liberal in largely endowing an academy, and an institution for poor girls. He was lean and delicate, and abstemious. He disliked and satirized pedantry. He was fond of the society of ladies, amongst whom he had only small talk and tea to encounter. His religious convictions regarding Christianity were by no means deep. He was created baron on the 6th March 1747, and died 27th January 1754, at the age of seventy. His character as a comic writer is drawn by Professor Rahbeck, who published the select works of Holberg in 21 vols. 8vo, Copenhagen, 1806–1814.

HOLINSHED, or Holingshed, Raphael, author of the *Chronicles of England, Scotland, and Ireland*, flourished in the sixteenth century. He seems to have been educated at one or other of the greater universities, and to have taken orders in the church; but the only fact in his history known with tolerable certainty is that he died in 1580. In the chronicle called by his name he bore a leading, but not an undivided share, as he received important aid from Stow, the antiquary; Harrison, a clergyman; Hooker, an uncle of the divine of that name; and Francis Boteville, a man of great learning, especially in antiquarian matters. Holinshed's share in the work comprised the history of England up to the date of the Norman Conquest, and from the Norman Conquest down to the year 1577, at which date the first edition of the *Chronicle* was published. The notice of Elizabeth's reign contained matter so offensive to her and her court that in the second edition, which appeared in 1587, some of the sheets were cancelled altogether. In subsequent reprints, however, these have been restored. The history of Scotland, incorporated by Holinshed in his *Chronicle*, is for the most part a translation from the Latin of Hector Boece, and is interesting as having furnished Shakspeare with the groundwork of his tragedy of *Macbeth*. The *Chronicle*, from being the work of so many different hands, presents, of course, great varieties of literary quality. Its real value depends on its learning and research, which have made it an invaluable aid to all who have since undertaken to illustrate the early annals of England.

HOLKAR, the name of three Mahratta chiefs, who at various times made themselves formidable to the British empire in India. See Hindustan.

HOLLAND.

HOLLAND is an European kingdom, formed in part of islands, but chiefly of that part of the Continent where the mouths of the Rhine are divided into several branches before it enters the German Ocean. This district is said to have owed the ancient name of Batavia, by which it was known to the Romans, to one Bato; but at what period he flourished is unknown; and the name is now scarcely used excepting amongst the poets of the district. By accounts collected from the works of Cæsar and Tacitus, we learn that the ancient tribes who inhabited this portion of Europe had been able to maintain their independence in spite of the attempts made to subdue them by the Teutones, the Cimbri, and other nations, who had conquered the rest of what was then called Gaul. The Batavians, says the last of these historians, excelled all the other people on the Rhine in military spirit. When subdued by the Romans they paid their tribute in soldiers; and from them was formed a cavalry, which composed the most efficient part of the Roman armies. They astonished the Dacians by the dexterity and bravery with which, completely armed, they swam their horses across the Danube to attack those people; and for a long period they formed the guard of the Roman emperors. A body of Batavians accompanied Agricola on his expedition into Britain, and were of great assistance in securing his conquests in the island.

Although the Romans at length overcame the Batavians, it was after a strenuous resistance. The last that submitted was the tribe of the Frisons, who inhabited the marshes. Drusus, the Roman commander, constructed a canal between the Rhine and the Zuyder Zee, and thus opened a way into the German Ocean to the Ems and the Weser, by which he was enabled to penetrate into the heart of Germany, and to subdue that country. During four centuries the Batavians formed part of the Roman legions; but amongst these, after the reign of the Emperor Honorius, their name is no longer to be found.

After that period the islands were overrun by the Franks; and the transactions relating to them have been mixed up with those of the adjoining Belgians. The Frieslanders, however, opposed and broke through the armies of the Franks, and made their appearance as a free, and in some measure a victorious people, on the left bank of the Rhine; and there, adhering to their ancient customs, upon which had been engrafted many of the principles introduced by the Romans, they long maintained their independence. These people had suffered the least from the invasion of foreigners, and retained through several centuries distinct traces of their ancient constitution, their national spirit, and their national manners.

In the fifth and sixth centuries the kingdom of the Franks, which had arisen out of the ruins of the Roman power, gradually extended itself, and in the seventh had subdued the last of the Batavian people, the long resisting Frisons. Under Charles Martel the last conquest was achieved, and a way opened by his sword for the introduction of the Christian religion.

When Charlemagne had obtained his extensive dominion, and the feudal system was introduced, and continued under his successors, the powerful vassals of the crown, to whom the lands were granted, by degrees acquired a sort of mitigated sovereignty; but being unable to maintain themselves without the assistance of their under feudatories, they were compelled, in order to secure their fidelity, to grant them advantageous conditions of tenure. The clergy, too, by pious usurpations or pious donations, became a powerful and independent corporate body. Thus, during the tenth, eleventh, twelfth, and thirteenth centuries, the whole of Belgium and of Batavia was split into several small dominions, the princes of which acknowledged a limited allegiance, some of them to the German empire, and others to the kings of the Franks. During this period Brabant, and afterwards Luxembourg, Limburg, and Gueldres, obtained the name of dukedoms; Flanders, Holland, Zealand, Hennegau, Artois, Namur, and Zutphen, were ranked as Graafschappen or countships. Utrecht was a bishopric, the prelate of which exercised civil authority also in Overyssel and Groningen. Amongst all these chiefs the Count of Flanders was the most powerful; and as, in 1383, that countship fell to the then more powerful house of Burgundy, the prince of that family, partly by intermarriages, partly by force, and partly by voluntary or purchased submission, obtained supreme authority over the whole of what became the seventeen provinces of the Netherlands.

This appears to have been the most flourishing period of these provinces. Agriculture was carried on with spirit, skill, and abundant results. Manufactures of linen, and especially of woollen goods, gave occupation to an increasing population; and foreign commerce was extensive and profitable. The commodities of India brought to the Italian cities were transmitted to Antwerp, Bruges, and some other places, where extensive depôts were established for foreign and domestic goods, and where, at the periodical fairs, the merchants of the northern kingdoms of Europe resorted, and transacted their commercial affairs.

The government of the Dukes of Burgundy was tempered by the privileges enjoyed by the cities, and by the nobility who possessed the land; and, though contests frequently arose between the sovereign and the states, they rarely came to open hostilities. When disturbances occurred, they were not of such duration, or so extensive, as to interrupt in any great degree the rapid growth of general wealth and progressive improvement.

Charles the Bold, the last of the Dukes of Burgundy, lost his life in a battle with the cantons of Switzerland in 1477. His eldest daughter Maria married Maximilian, duke of Austria, and received the Netherlands as her portion; and her grandson, born at Ghent, afterwards Charles V., emperor of Germany, thus became sovereign of those countries and of the kingdom of Spain from the moment of his birth. Before the marriage of Maria, and also under Maximilian, when he had become emperor and guardian of his son, attempts were made to lessen the influence of the states. But these were powerfully resisted by some of the cities, and especially by Bruges, in 1487, and by Sluys about the same time. Bruges was sufficiently strong to resist the encroachments; but Maximilian, in despite of its privileges, blocked up the port of Sluys for ten years, which caused the foreign ships that before crowded to that place to repair to Antwerp and Amsterdam; and these cities from that period became the two principal seats of foreign commerce.

The Netherlands, at the end of the fifteenth century, became the great school for the fine arts. These had been introduced from Italy; and the artists of the Low Countries were soon successful rivals of their masters of Florence, Bologna, and Venice, in painting, in statuary, in architecture, and in engraving. The art of printing, if not invented, was first made known at Haerlem, and was soon practised in other cities of the Netherland provinces.

At the accession of Charles V. the situation of the Netherlands became widely changed. Instead of a paternal government, the chief of which in a great measure depended on the prosperity of these provinces, they were converted into a dependent, and, though rich and populous, an insignificant part of a large empire, to the promotion of whose greatness, whether for good or for evil to themselves, they must in future be almost wholly subservient.

Between the Flemings and the Spaniards an excessive distaste was mutually felt, which soon attained to the most inveterate hatred. This originated in the difference of genius, of manners, customs, and mode of government, and was quickly increased by the regret natural to a powerful people, such as those of the Netherlands deemed themselves, at being incorporated, and thereby almost swallowed up, by another nation. Steps were early taken by Charles, under the pretence of introducing unity in his territories, that had a tendency to undermine the privileges which the Netherland states had zealously defended and long maintained. Before his accession a legal tribunal had been established at Mechlin, to which appeals might be made from all the legal tribunals of the confederate states; and as none but natives were judges, and their decisions were guided by the ancient laws, it was looked up to with confidence, and considered as a security to their constitutions. This tribunal was, however, nullified by being placed under an imperial court, established at Brussels, several of the members of which were foreigners, and all of whom were dependent on the royal favour alone. This imperial court was naturally viewed with a jealous eye, and was ill adapted for the protection of those rights to which the people were attached.

The growing expenses of the hostile operations of Charles in other parts of his extended dominions, made his demands on his Netherland subjects much heavier. In spite of their ancient right of levying taxes, he imposed some that were new, and increased others. The history of this reign contains constant repetitions of subsidies required, which were at first rejected or deferred, but at length yielded, though with reluctance and discontent.

Another subject of murmuring was the introduction of foreign troops, that is, forces belonging to the other dominions of the emperor, as well as recruiting his armies in the Netherlands without the consent of the states; circumstances which, besides being contrary to the constitution, involved them in wars to which they were indifferent or repugnant, and which were injurious to their interest as a commercial people.

Charles felt that the commerce of his subjects could alone enable him to extract from them those pecuniary supplies which his general government needed; and so far he protected their manufactures and mercantile affairs, and in some cases even recalled edicts, at the requisition of his Flemish subjects, which he would have without hesitation enforced at Madrid. The most influential of all the causes which arose in the reign of Charles V. was the religious reformation which had commenced in Germany, had spread in France, and from both these countries had been introduced into the Netherlands, chiefly in the trading cities, and in them had gained numerous adherents. The full effect of this, and of the other causes which have been here noticed, did not appear until the abdication of the emperor had elevated his son Philip II. to the extensive dominions of his father.

The religious excitement gave some uneasiness to Charles, and measures were feebly applied to check the progress of the new opinions, to which, when not actuated by political views, he at one time seemed not to be strenuously inimical. Had the emperor been disposed to severity towards the professors of the Protestant tenets, any measure of that nature would have affected the interests of commerce, and have tended to diminish the revenues he drew from that source. The foreign merchants who had establishments, or frequented the fairs, in the Netherlands, brought with them from Germany, England, France, and other countries, the doctrines and the writings of the Protestants. These were diffused amongst the natives, and made a great impression; and any attempts to destroy their intercourse, or to punish them for their opinions, would have driven commerce, as it did a few years later under Philip II., to the other markets of Europe, where greater religious freedom was enjoyed.

Towards the close of his reign, Charles issued indeed some most severe laws against those who professed the new religion. These were in some cases applied with unfeeling cruelty, though they tended but little to diminish the progress of the dissident principles. He had resolved, after the successful issue of his wars in Germany, to reduce his Netherland subjects to uniform obedience to the Roman Catholic religion, and for that purpose he designed to have introduced the Inquisition. The fear alone of that dreaded tribunal in Antwerp suspended immediately all commerce, and the most eminent foreigners made instant preparations to remove. There were neither buyers nor sellers to be seen, the value of the buildings was destroyed, and all the operative labourers were discharged. Money totally disappeared, and no taxes could be collected. At the earnest recommendation of the Duchess of Parma, as vice-regent, this edict was suspended. The common tribunals were directed to practise no molestation on the foreign merchants; and, instead of the Inquisition, a milder court, at least in name, was framed, and called the ecclesiastical tribunal. In the other provinces, however, much severity was beginning to be practised, not long before the abdication of Charles; but, severe as these were, the remembrance of them was speedily obliterated by the more savage cruelties practised under the reign of his son.

The reign of Charles was, upon the whole, beneficial to the United Netherland Provinces, and he left that division of his dominions in a most flourishing condition; so that for its extent it was by far the most considerable state in Europe. Their taxes were by no means heavy, though their trade was most extensive; and the mechanical genius and persevering industry of the inhabitants had rendered the Low Countries the workshop of Europe. When the emperor, at his solemn abdication, delivered over these provinces to the rule of his son, they are reported to have contained three hundred and fifty cities, and six thousand three hundred towns and large villages, besides numerous hamlets, farm-houses, and castles. These comprehended the four dukedoms of Brabant, Limburg, Luxembourg, and Guelderland; the seven countships of Artois, Hennegau, Flanders, Namur, Zutphen, Holland, and Zealand; the margravate of Antwerp; and the baronies of Friesland, Mechlin, Utrecht, Overyssel, and Groningen. Statistical researches were not much practised at that period, and no accurate views can be obtained of the extent of the population; but there is good reason to conclude, that, though at present the Netherlands are the most densely peopled of any part of Europe, the numbers then were more than equal to what they are now. The seven provinces which afterwards formed the republic were probably less populous; but the other divisions, where manufactures were more generally carried on, were, from all accounts, proportionally more crowded. Philip II. ascended the throne on the abdication of his father in October 1555. He had been educated in Spain, and had imbibed the retired and stately manners of that country. He spoke no other language but Spanish, and, except the short time he had passed in England after his marriage with Queen Mary, he had scarcely ever left the peninsula. He was most zealously attached to the Roman Catholic religion, and not less so to the unrestricted exercise of arbitrary power. He was distrustful of those who administered public affairs, was nearly invisible to his subjects, and the few who had access to his presence were commonly disgusted both with his manners and with the punctilious formalities with which their introduction was attended. He was deemed insensible to human sufferings, and was equivocating, if not insincere, in the replies he made to the petitions of his subjects.

He remained in the Netherlands from his accession in 1555 till August 1559, when he embarked for Spain, and never afterwards returned. The measures he introduced during his stay, his repulsive manners, and the humours he displayed at his departure, all tended to strengthen that aversion, mingled with suspicion, which had begun to manifest itself during the reign of his imperial predecessor.

The most obnoxious measures to the people were, first, a design to abolish several of the monastic establishments, in order that their estates might be converted into revenues for new bishoprics, the incumbents of which were to be the instruments of introducing the Inquisition into the provinces. That institution was held in such abhorrence, that it encountered every obstruction which could be opposed to it, both by the Catholics and the Protestants. It had met also, at the court of Rome, some obstacles which caused delay, so that the arrangement was not completed when the king departed for Spain. The second cause of complaint was the retention of foreign forces within the states. When the king came to the throne, a war was carried on with France; but the French having been signally defeated at the battle of St Quentin in 1557, a peace was, after long negotiations, completed at Chateau-Cambresis. The withdrawing of the troops, consisting both of the Spanish infantry and of some German auxiliaries, was eagerly looked for by all the inhabitants. The latter were disbanded and sent home, but the former were retained, and proved dreadfully oppressive to the country. Vander Vynckt, the faithful historian of Flanders, says, "the Spaniards were so elevated with their late successes against the French, that they thought the ransom or the pillage of the whole of the Netherlands would be an insufficient recompense for the actions they had performed. They lived at free quarters on the country, and trampled upon the people without pity." In fact, receiving little or no pay, or that pay being much in arrears, they were of necessity instigated to all kinds of disorders, and led to practise the most abominable oppressions. The remonstrances of the states were coldly received, and though assurances were given that the grievance should be removed, and the period for it was fixed, it was delayed from time to time, and ultimately consented to in appearance only, as they remained on the frontiers, ready to re-enter when the ulterior measures which were in preparation should require their assistance. As one means of delaying the departure of these troops, two legions were proposed to be placed under the command of the Prince of Orange and Count Egmont, two of the most patriotic and popular of the nobility. But their integrity resisted the temptation; they declined the command, and this rendered the continuance of the troops the more obnoxious.

A third cause of complaint was, a violation of the ancient constitution of the states, by introducing into the higher executive and judicial offices persons of foreign birth. When Philip left the Netherlands, the government was conferred on the Duchess of Parma, a natural daughter of the Emperor Charles V. She was to be assisted by a council of state, composed of the Prince of Orange, the Counts Egmont and Horn, Granvelt bishop of Arras, Count Barlaimont, and Vigilius de Quichem. But by secret orders, but which soon transpired, a committee of this council, consisting of the three last named, was empowered in most cases to communicate alone with the duchess, and in all cases to decide on the advice which was to be given to her. Thus the Prince of Orange and the two counts were mere ciphers, and rarely attended the council. Barlaimont was a mere creature of Granvelt, who attended only to the finances, of which he was chief, and was commonly absent when other affairs were under consideration; Vigilius was a man of profound scholastic learning, very politic, and very yielding; so that, in fact, the whole power was conceded to Granvelt. He was a native of France, and had distinguished himself by his learning, but more by his subservience to the rigour and the caprices of Philip. By these means, from the low condition of a parish priest, he was raised to the episcopal rank, and finally to the dignity of a cardinal. His being a foreigner was the pretext, but his arbitrary disposition and intolerant rigour the causes, of general aversion; and the firmest and most pointed representations of the assemblies of the several states were solely but unavailingly directed towards him. He alone conducted all affairs, and to him the secret orders of the king were conveyed.

The three members of the council who had been named on account of the estimation in which they were held among the natives of the Netherlands, though they were utterly inefficient as members of the board, should not be passed over without short notices of their rank and character, on account of the vast interest which has been excited by the events they directed, and the fates they experienced.

William of Nassau, prince of Orange, was one of the greatest men of his own or any other age. He had in his youth been brought up in Germany, his native country, amongst Protestants, whose creed his father had adopted. Being of an illustrious house, he was early introduced to the Emperor Charles, whose favour and confidence he obtained, and he was employed by him in some most honourable commissions and embassies. He came to the possession of the family inheritance on the death of an uncle and a cousin, consisting of extensive estates in Burgundy and the Netherlands, and thus was by far the richest of all the nobles of the country. By his wealth he was enabled to live magnificently when ambassador in France and in England, and afterwards at home when governor of the provinces of Holland and Zealand. He was as highly estimated in foreign countries as in the Netherlands, and had formed numerous alliances and friendships in England and France, and others still more considerable in Germany. He was a man of penetration, courage, and resolution, with enlarged and accurate political views. His measures were maturely considered, but when once determined upon, nothing could shake them. In the greatest adversity he was firm and tranquil, and he possessed in his mind inexhaustible resources. He was remarkable for his taciturnity, from which circumstance he was sometimes distinguished by the name of William the Silent. An Italian proverb has appropriately described him, *Tacendo parla, parlando incanta.*

Lamoral count Egmont was also a nobleman of the first rank, of a family originating in Holland, some members of which had in former times been the sovereign Dukes of Guelderland. His mother, the heiress of the house of Luxembourg-Fiennes, had brought to the family of Egmont estates in Flanders of vast extent and riches. He was adored by the inhabitants of Flanders and Artois, of which provinces he was the governor, and was generally considered as the fittest person to have filled the dignity held by the Duchess of Parma. He was generous, frank, disinterested, and open hearted. He was besides a good general, possessing intrepid courage, and had distinguished himself in the war with France. He was less adroit than the Prince of Orange, and had less of foresight, but he was as eminent in the field as the other was in the cabinet. These men were at one time rivals for power, but a common interest closely united them. Philip de Montmorenci, count Horn, was an admiral, and in his command of the naval forces had displayed the most intrepid courage, and had rendered great service to the Spanish government. He had been governor of the provinces of Zutphen and Gelderland, and by the management of Granvelt had been suspended and sent into Spain, where he is said to have acquired a thorough knowledge of the operations intended against the liberties of his country, and communicated them to the Prince of Orange. He was reported also to have then had some intercourse with Don Carlos, the heir to the throne of Spain, who himself was supposed to feel differently on the affairs of the Netherlands from his father King Philip.

With these three leaders were connected others of rank nearly equal, the whole of the inferior nobility, and a very large majority of the burghers, merchants, and manufacturers of the cities and towns; and in particular almost the whole of those people who were connected with maritime transactions, either as owners or navigators of vessels.

We return now to the causes of complaint which were made in the Netherlands. The fourth of them was, the omitting to call together the general assembly of the states. Though under the reign of the Emperor Charles the power of that body had been much curtailed, they were yet the organ of the opinions and feelings of the more respectable part of the nation. Their views and complaints were freely communicated to the government, and exercised influence on its decisions. One of the last and most decisive instructions given by Philip to the Duchess of Parma, before his departure for Spain, forbade the assembling of this body.

The chief points upon which the subjects felt aggrieved are only here noticed, though there were many others, some of a minor and some of a local nature, all which, combined with the general disgust felt towards Spain and the Spanish monarch, tended to shake the authority of the king, by indisposing the civil tribunals from following up with zeal the ordonnances which from time to time were issued by the sovereign.

These complaints had at a very early period excited secret associations amongst the nobility and gentry which were in opposition to the extension of the severe penal laws. One of these associations was formed as early as 1556, by Martiner baron of St Aldegonde in Breda, a confidential friend of the Prince of Orange. He, with ten or twelve others of equal rank, drew up a declaration, then known by the name of the *Compromise.* It contained execrations against the Inquisition, which it painted in the most horrible colours. It accused foreigners of having seduced the king to refuse the abolition of his rigid ordonnances, that they might be enabled to gratify their ambition and their avarice; and it concluded with declaring, that they were united to assist the oppressed, to resist violence, and, above all things, never to submit to the establishment of the Inquisition. When this compromise had been signed at Breda, numerous copies of it were made and circulated throughout all the provinces, from Artois to Friesland. It was signed with avidity by all classes, from the highest nobility to the lowest artisans. This association at length became so extensive and bold as to determine on an application to the regent, for which purpose the leaders requested an audience, that they might lay their complaints before her. This request, after much hesitation and with some symptoms of alarm on the part of the government, was at length granted. The nobles assembled at Brussels, attended, according to the custom of the age, by their numerous followers, and, marching to the palace in a long train in regular order, were admitted to an audience. The address was read by Brederode count of Utrecht. It contained strong professions of obedience and loyalty, and asserted that the associates were innocent of the charge of which they had been calumniated, of having entered into engagements with foreign powers. In conclusion, a convocation of the states-general was requested, and in the mean time a provisional suspension of all inquisitorial measures and proclamations, until a reply could be received from the king, who was then in Spain. An equivocal reply was given, the substance of which was merely that more temperate measures would be pursued till the orders of the king were received.

This assembling of the nobles gave to the associates a name which was assumed and long continued as a mark of distinction. During the audience at the palace, the duchess appeared somewhat alarmed at the great number of persons which composed the deputation. Count Barlaimont, one of her suite, in order to calm her disquietude, whispered, but sufficiently loud to be heard by those who were nearest, that they were nothing more than *un ramas de gueux,* a crowd of beggars. On this being reported at a convivial meeting of the nobles, one of them, as a toast, gave *vivent les gueux,* which was received with acclamation, and the name afterwards adopted; and their clothing and ornaments were so worn as to exhibit emblems like those in use amongst conventual mendicants and other beggars, one of the most distinguishing of which was a sack thrown over the shoulders, on which was frequently painted the motto of the association, *Fidèle au roi jusqu'à la besace.*

The exhibition of strength on the part of the associates led to a series of negotiations between the vice-regent and the party, which at length was terminated on the 23d of August 1566, by the duchess provisionally, till orders could be received from Spain, agreeing to suspend the introduction of the Inquisition, and in the mean time to submit her other measures to the revision of the states-general.

Even this kind of truce was only conceded in consequence of some tumultuous and outrageous assemblages, partly excited by the Protestant preachers, but of which they soon ceased to have any power of direction or control. The assemblies first collected by field preachers were composed of those who had imbibed the Protestant opinions, and were held on the frontiers of Liège, about St Trond. They were soon joined, out of curiosity, by numbers anxious to hear the new doctrines, but speedily afterwards by all the wandering tribes of outlaws, vagabonds, and plunderers; and at length they became so numerous that no resistance could be made to them in the open country, or even in the cities which were not fortified and well garrisoned. The Catholic writers of the period represent these assemblages as being composed principally of the sectarians of Germany and the Calvinists of France, joined to the Anabaptists of Leyden and other parts of Holland. It seems evident, however, that these were very early outnumbered by others whose chief objects were plunder and destruction. Their first operations were to attack and rob the monasteries in the open country; they then seized on the churches, and destroyed all the images and other appendages of the Catholic worship, carrying away with them whatever was portable and valuable. The peaceable inhabitants appeared everywhere panic-struck, and the desolating power thus let loose was opposed by no obstacles; so that at length all the cities except Brussels were more or less subject to the depredators. Ypres, Tournay, Valenciennes, and Oudenarde suffered the most. At Antwerp the Prince of Orange suspended the destruction as long as he remained there, but after his removal the insurgents gained the superiority, and were enabled to destroy the images and ornaments of the cathedral, as well as those of the other churches and monasteries, in that city. This devastation was like a hurricane, and though the storm passed over in a short space of time, its effects were frightful, and its destructive operations extensive.

The duchess, though about to leave Brussels, and seek safety in Mons, was persuaded by her council to remain in the capital, where intimidations on one side, and proposals to treat with the insurgents on the other, were urged with vehemence. To the latter she at length yielded, and authorized the Prince of Orange, with the Counts Egmont and Horn, to treat with the chiefs of the insurgents, who still continued in St Trond. This measure was so far successful for the time, that, after the provisional agreement already noticed, a treaty was concluded with the leaders at St Trond, and signed on the 25th of August. It was agreed that the preachers might continue their religious practices in the places where they actually did exercise them, that the people might attend them, but unarmed, and cause no trouble to the Catholics. The nobles were to renounce the confederation, and all were to lay down their arms, and assist in restoring and re-establishing the estates, the churches, the monasteries, and the hospitals that had been plundered, and indemnify those who had suffered.

A temporary lull was thus procured, though frequently interrupted by local explosions. All were waiting with impatience for intelligence from Madrid, whither couriers were immediately forwarded after the pacification, with despatches from the duchess to King Philip. The letters to Spain were expressed in the most melancholy strain. The duchess confessed that she had granted to the insurgents terms that were degrading to herself, and which she could not relate without shame and grief. She affirmed that she had long resisted, but, weakened by fever and sleepless nights, had at length yielded; that with anguish of mind and bodily pain, and the fear of greater evils, she had granted pardon to the rebels, and had acceded to their demands, but that she had done nothing in the name of the king, but only in her own; and that he might disavow and undo what she had done, as his majesty was no party to the acts. The despatch concluded with an earnest solicitation that his majesty would not delay his journey to the Low Countries till the spring, but come immediately to Brussels.

Philip received the despatches at Segovia, where he was confined by sickness; and though he read and remarked upon them, no answer was returned till he was enabled to remove to Madrid and assemble his council. In that council it was seen that the vice-regent had in no way committed his majesty, and the answers were dictated under that assumption. Two despatches were drawn, one of them ostensible and the other secret. They are to be found at length in Strada, and the substance of them may be thus abridged. The first or public letter announced the birth of an infanta, and that the king had removed to Madrid to make the necessary preparations for his journey to Flanders; that a convocation of the states would be no remedy for the existing evils, but an injury to the honour and the conscience of the king; and that the best measure, in case of necessity, would be to repel force by force, in which circumstances she might securely count on the aid of the well disposed people. The secret despatch was more laconic. It enjoined attention to former orders, and to the public letter, on what related to the convocation of the states-general; and if any force was exercised towards the government, to trust to God and his providence, but to do nothing that should appear, either directly or indirectly, to have proceeded from the opinion of the king.

It was the policy of the court of Spain at this period to keep every thing in the Netherlands in a state of total suspense. For this purpose rumours were spread of the king's intended journey. The time was fixed, the preparations were made, the route was determined, and the attendants were named. It was however only a kind of grimace, though, to give it more the appearance of reality, application was made to the king of France for permission to pass, and also the Duke of Savoy was consulted respecting the fittest passage over the Alps, in case the king should proceed to Italy by sea. These measures satisfied almost the whole of the inhabitants that their sovereign would speedily appear amongst them. The Prince of Orange alone was not deceived. He had emissaries of talent in Madrid, in Rome, and in Vienna, and indeed wherever important intelligence could be obtained. In 1565 Catherine de' Medicis, with her son Charles IX., had a meeting at Bayonne, to which King Philip and his queen, a daughter of Medicis, were to have repaired. The king, however, did not join them, but the queen did. It was represented as a mere family party, at which the ambassadors of other states were not expected to attend. At the meeting the females concocted a treaty between the two kings, which was to be kept secret from all but themselves. It engaged to extirpate all heresy and heretics, not only from their own dominions, but from all the other parts of Europe in which Protestantism had already been embraced. The secret was well kept, and the meeting was attributed to some projected family marriages, which Philip represented to his ministers as a matter which would be best arranged by the females. Walsingham, the ambassador at Paris of Queen Elizabeth, within little more than a year gained the particulars of the treaty, and communicated them to his court, and thence the knowledge of it was conveyed to the Prince of Orange, who maintained the most profound secrecy till the most useful moment for its being made known had arrived.

It was generally believed that the prince had the most complete knowledge of what passed in the cabinet of King Philip, though it is now unknown if, as some suspected, he had the intelligence from his son Don Carlos, or, as others imagined, from one of his secretaries. It is said, that from his perfect knowledge of the transactions and opinions of the French court, and of what had passed at Bayonne, he had predicted the massacre of Saint Bartholomew, and had informed the Admiral de Coligny of the plot, putting him on his guard against the caresses and the treachery of the court, but which, unfortunately for the illustrious victim, did not save him from the miserable fate which he at length suffered. The Prince of Orange was possessed of large estates in Germany, and, by blood as well as by marriage, was closely connected with many of the smaller sovereigns of that country, who had embraced and introduced into their dominions the doctrine and the worship of the Protestants. Even the emperor, though a firm adherent of the Roman Catholic church, was in some measure influenced by him. He was induced to write to King Philip, expressing his good will, but pointed out to him that he was engaged in a war with the Turks, that a great part of Germany interested itself in the fate of the Netherlands, and that those who had adopted the confession of Augsburg would never allow the inhabitants of these provinces to be oppressed. He therefore recommended a negotiation with Orange, Egmont, and Horn, and offered his mediation to accommodate the differences. The court of Spain rejected this interference between the king and his Flemish subjects; but the knowledge of this correspondence served to strengthen the purpose of the Prince of Orange, who soon became acquainted with it, to adopt the precautionary measures which his situation required.

The Prince of Orange having learned, by his emissaries at the court of Madrid, that the preparations for the king's journey to the Netherlands were merely adopted to quiet and mislead the public, and that, on the contrary, it had been determined to pursue the most rigid measures, and intrust them to the Duke of Alba, determined on his course of action. He immediately resigned all the offices he held in the Netherlands, and withdrew himself and his family to his territories in the duchy of Nassau in Germany.

The Duke of Alba was reputed in that age to be cruel, crafty, proud, and avaricious; and his name was held in abhorrence throughout the Netherlands. Although it was resolved that he should have the sole power, yet the purpose was concealed even from the regent herself. Philip continued to assure her that he was resolved to come as soon as possible, and that the Duke of Alba only preceded him, to smooth the way, and so arrange affairs that he might on his arrival the more easily restore tranquillity; that in the mean time the duke would command the army, and attend to the fortifications, and the security of the country, but still in subordination to the authority of her highness. The knowledge of this appointment could not be long kept secret, and its disclosure produced universal consternation. The great nobles, such as the Prince of Orange, the Counts Calembourg, de Bergh, Brederode, and others, had early sold parts of their estates, and raised money by mortgages on the other portions of them. All that could, prepared for their removal. The inferior nobility, the rich merchants of Antwerp, the wealthy burghers of all the cities, resolved to expatriate themselves and their families. Soon after the mission of Alba was publicly made known, the duchess wrote to the king to say, that already more than one hundred thousand persons had abandoned their domicils and their country. The Low Countries were at that period at the height of prosperity. The cities were opulent and contiguous, the towns, villages, and hamlets, resembled the cities of other countries, and almost touched each other. It was most densely peopled, and so cultivated that no waste land was to be seen. The commerce was active, and the inhabitants, from industry, were easy in their circumstances, well fed and well clothed. They were the objects of envy to strangers, and viewed with peculiar jealousy by the Spaniards, who saw their condition, and compared it with that of their own country.

The emigrations caused by the first intelligence of the approach of Alba alarmed the duchess, who issued edicts designed to tranquillise the people, and these had some effect; but they were disavowed by orders of the king, and some who had been induced to return were subsequently the victims of their confidence. Afterwards, when the severities of Alba began to be exercised, the emigrations were increased; and though orders were issued to prevent it, and intrusted to the Spanish troops to execute, they came too late. A great number of families had expatriated themselves, and taken with them whatever of their property they could save. Those who were left were chiefly artisans, who could find no employment when their masters had forsaken them, and were thus compelled to seek the means of subsistence elsewhere. A great part of such as were capable of bearing arms joined the Prince of Orange, or enlisted in the armies which the princes of Germany created. Others of them sought an asylum in the imperial cities, and there exercised their trades. Some threw themselves into the Walloon country and into Picardy, for the interior of France was then in greater commotion than even Flanders itself.

The greatest removals however were to England, where, by the orders of Elizabeth, all the ports were open to them, where their property was protected, and where they introduced new fabrics of various kinds, and established those manufactures which have become in process of time the foundation of the commerce and the wealth of our country.

The Duke of Alba, in 1567, embarked with his army at Barcelona, and landed at Genoa. After some stay at Milan, he passed the Alps by Mount Cenis, and proceeded to Franche Comté by the frontiers of Burgundy and Lorraine, and arrived in the beginning of August at Luxembourg, whence he proceeded to Brussels, and entered that city on the 22d of the same month. At his first appearance his conduct convinced the duchess that he was come to exercise supreme power, and in a short time she withdrew from the government. He conducted himself in a most caressing manner to Horn and Egmont, consulted them on military subjects, and especially in constructing fortresses at Valenciennes, Antwerp, and Groningen; but suddenly at the council arrested them, consigned them to separate prisons, seized all their papers, and obtained possession of their money, jewels, and other valuable effects.

When the duchess had quitted Flanders, Alba proceeded with his more violent measures. In January 1568 he erected a judicial tribunal, well known in the annals of the country by the Flemish name of *Bloet-Raet*, or sanguinary council. Alba was himself president, and Vargas, a Spaniard, vice-president. The other members were neither of the privy council nor of the council of Brabant, but, with the exception of two persons who never took their seats, consisted of individuals on whose concurrence Alba could securely rely.

This tribunal commenced by citing before it all the nobles and the citizens, whether absent or present, whether living or dead, who had signed the compromise, such as the Prince of Orange, the Counts of Nassau his brothers, the Counts Hoogstraten, Calembourg, and Brederode, and even the Marquis of Berghes, who was deceased. The Prince of Orange, who had decided on his part, replied in terms of defiance. He asserted that he was a member of the German empire, and as such answerable before none other than the emperor himself; and that, as one of the Spanish order of the golden fleece, he could only be judged by the king when holding a chapter of that order. The others made replies rejecting the authority of the new tribunal, and avowed their junction with the forces which the Prince of Orange was collecting.

The citations were numerous, but the most detailed account is that preserved at Ghent. One hundred and fifty persons, consisting of nobles, patricians, and burghers, were summoned on fixed days to appear at Brussels. Of that number only eighteen presented themselves, the others having emigrated or being concealed. These, conscious of their innocence, were allowed to defend themselves before the tribunal, and were then bound two and two together, and thus marched to prison. The process was not long deferred; they were condemned to death, and perished on the scaffold, some by the sword, others by the halter, according to their respective ranks. Numerous other prosecutions, which terminated in death and confiscations, were carried on towards persons in Ghent; and if the number executed in the whole of the country were in the same proportion to those in that city, it may be true which Alba is said to have boasted on his return to Spain, that more than eight thousand persons had perished on the scaffold during his government of the Netherlands.

The executions of the Counts Egmont and Horn were deferred till June, when, by a process not to be justified by any law, they were condemned to suffer death. They were brought from their confinement in the prison of Ghent, surrounded by two thousand Spanish troops, and decapitated in the Place de Sablons, at Brussels, on the 5th of June 1568. The illegality of these executions was loudly complained of, and produced a great effect over the whole of Europe. Even the emperor and the other Catholic princes loudly condemned the proceeding, whilst many of the Protestant princes were induced by it to lend their aid to the confederation which the Prince of Orange was forming to avenge his friends, and to rescue the country from the miseries it endured.

The army which Alba brought with him from Spain, with some additions on the way, amounted to 20,000 men, one half of which consisted of Spanish infantry, who were in that day considered as the best troops in Europe. They were well disciplined and well commanded, but were much disposed to mutiny, especially when, as was often the case, their pay was in arrear; and this disposition was afterwards often displayed in the most critical circumstances, to the great injury of the service in which they were employed. The desolation of the provinces, and the horrid cruelties which had been perpetrated, at length gave birth to that ruinous and obstinate civil war, which continued so long that none of those who commenced it lived to see its termination.

When the Prince of Orange retired into Germany, he had wished to have collected a force which might have harassed the army of Alba during the march from Italy to the Netherlands; but the princes of Germany were not so alarmed at the prospect of the danger which threatened them, as to assist him to such an extent as he deemed necessary for his purpose, and Alba with his army entered without molestation. The prince had time in his retirement to form his plans deliberately, to calculate on future probabilities, and to be ready to act when the moment for action should arrive. The first cruelties of Alba made a deep impression on all the Protestant princes of Germany, and this impression Orange was skilful enough to turn to his advantage. By the deaths of Horn and Egmont such indignation and resolution were excited in them, that they offered to Orange their wishes, their councils, their troops, and, what is almost incredible, their treasures. Amongst the most prominent of these was the Prince Palatine, with whom the Prince of Orange held a secret meeting at Strasburg, at which some of the leaders of the Huguenots in France were present. Even the Catholic princes were so inflamed at the treatment of Horn and Egmont, that, if they did not assist, they did nothing to impede Orange in his negotiations. The assistance thus obtained, with the aid of a pecuniary nature from Queen Elizabeth of England, and recruits from the Protestants of France, enabled Orange to take the field.

The prince was straitened for money; and his army, though numerous, was badly composed. The Germans and the French were new levies, hastily raised, eager for booty, and in general ill disciplined. Though they were not subject to his sole command, he could not safely disgust them, nor could he allow them to plunder. He knew, too, that at the end of the campaign these succours would quit him, because he was not in a situation to maintain so numerous a body. The greater part of the fugitives from Flanders were destitute, and the prince foresaw that these must soon become a charge which he would be unable to bear.

With forces of such motley composition, Orange determined on a bold and sudden attempt to enter the country on one side or the other, and to sound the tocsin over the whole of the Netherlands. On this plan he formed four bodies, to enter the country at different points. The first of them was to penetrate on the side of Liège, and to enter Gelderland. It was commanded by Count Hoogstraten, the only nobleman of distinguished rank who had been so fortunate as to escape from the fangs of the Duke of Alba. The second corps consisted of the French Huguenots, commanded by De Cocqueville, and they entered into Artois. Neither of these corps were strong, nor do they appear during the whole campaign to have effected any other object than, by skirmishing, to have distracted the attention of the enemy, and thus kept him from strengthening the more important points. The third corps was better composed and more numerous. It was commanded by Prince Louis of Nassau, brother of the Prince of Orange. It commenced the war by entering Friesland, where he was opposed by the king's army under the Count Arenburg, whose force was augmented by Spanish infantry and cavalry. When in presence of the enemy, he was forced to give battle, by the taunts of the Spaniards, who accused him, from his being a Fleming, of favouring the party of Orange. He led his troops to the combat, and fell in the attack. His army was completely defeated and dispersed, with the loss of its cannon, baggage, and a large sum of money which was destined to pay his troops, as well as others then in Groningen. The Frisian peasantry put to death the fugitive Spaniards; but the Germans and Flemings, who were mixed with them, were either liberated or joined the victorious troops.

The Duke of Alba was at Brussels when this disastrous event happened; and instantly, after venting his rage by numerous judicial assassinations, he repaired, with what troops he could collect, to Groningen, where he was joined by the garrison of that city. The troops of Prince Louis amounted to 12,000 or 14,000 men, and that of Alba was nearly of equal number; but the army of the latter was well trained and well disciplined, whereas that of the former was a mass of strangers, difficult to restrain, with little experience and less discipline, disposed to mutiny for want of their pay, and ready to desert their colours after any reverse. Prince Louis found it necessary to retreat from Winschotten, where he had gained his victory, and remove into the German province of East Friesland. He took up a position defended on one side by the river Ems, and on the other by that bay of the Zuyder Zee called the Dollart, and having at his back the city of Embden. He threw up intrenchments mounted with cannon in his front, and with better disciplined troops might have maintained himself till his brother the prince, who was advancing with a numerous force, could arrive to his relief. Alba pressed eagerly forward, and, at his approach, the troops of Nassau broke out into mutiny; and though it was partially quelled, a body of auxiliary troops who had joined it from Oldenburg, instead of waiting the attack within the lines, rushed out without orders, and threw themselves upon the Spaniards, by whom they were cut to pieces, and the opening thus made was entered by the enemy. The route became complete, and the Spaniards were amply revenged for the late disaster at Winschotten. Many of Nassau's troops were killed, more were drowned in the Ems, the cannon, colours, and baggage were captured, and the prince with a few of his followers threw themselves into the city of Embden, whence, from their knowledge of the country, they succeeded in making good their retreat.

Whilst these transactions were passing on the eastern side, the Prince of Orange had been collecting his fourth and principal army on the western side, and mustered, about Aix-la-Chapelle and Liège, a body of nearly 28,000 men, which in that age was a large army. Being much superior in number to the army under Alba, the Prince of Orange was desirous of a battle, and made all possible attempts to bring it on. But the Duke of Alba, knowing the nature of his enemy's forces, and that it was beyond his power to keep together so large a body from one season to another, acted purely on the defensive. This course he adhered to with firmness, though often urged by his officers and troops to lead them to battle. The campaign was thus passed with no other operations than occasional skirmishes or advances and retreats. The prince was compelled to dismiss the greater part of his forces, and to retire, with the few left to him, into winter quarters, when Alba did the same, and both were actively employed during the winter in the necessary preparations for the following spring.

The events which caused and accompanied the commencement of the troubles in the Netherlands have been related in a more circumstantial and detailed manner than our limits will allow to the subsequent proceedings. After the first indecisive campaign, there was a kind of suspension of hostilities, from the exhaustion of the opposing parties. Alba was employed in extorting money from the public bodies, and from individuals, to an unheard-of extent, and with intolerable severity. One demand was called the tenth denier, by which one tenth of the amount of all sales were to be paid; a tax which served to impoverish the country, to suspend all industry in trade, and which ultimately tended to exasperate the inhabitants, and throw them into the arms of the insurgent party. The Prince of Orange, on the other hand, was occupied in negotiating treaties with the German princes, who assured him of succours both of troops and treasures. He also visited France, where Admiral Coligny, the chief of the Protestant party, after promising his aid, suggested to him the idea of creating a naval force. This was instantly adopted, and a party of sailors, of those called Gueux-marins, seized upon Brielle, a town on the island of Hoorn, by which they secured an asylum for the shipping, and whence they gradually extended their conquests to the other towns and cities which command the entrance to the ocean, and secure those places from naval attack. This was the first step in the formation of that naval power by which the Hollanders became ultimately enabled to secure their independence. Seamen from all parts flocked to the maritime towns as rapidly as they declared for the Prince of Orange; and in Dort, Flushing, Rotterdam, and, indeed, all the places where there were no Spanish garrisons, they joined the prince. Fleets were equipped, which seized on all the Spanish vessels they met with, even in the British Channel, and kept open a communication with the ports of England, whence, by the proceeds of the captures, they could procure stores, arms, and ammunition, to carry on their warlike operations. The growth of the naval power was so rapid, that within three months after the capture of Flushing, no less than one hundred and fifty sail of armed vessels, well manned and equipped, were despatched from that place alone. The canals and rivers which intersect the country were filled with barges and gun-boats, which landed at the Spanish posts, and carried away arms and other effects from the very gates of Ghent and Bruges.

Alba, who was busied in extorting the tenth penny, looked with contempt on the seizure of Brielle; but soon awoke to the consequences, and began to draw together his troops to punish the Gueux-marins. His attention was, however, too powerfully drawn to another quarter, and they were left without molestation. The Prince of Orange, the moment he knew himself secure of the naval asylum, began his land operations. At the head of 20,000 men he entered Gelderland, seized Ruremonde, Tongres, St Trond, and Tirlemont, and entered Louvain by treaty, where he rested. His brother Louis, aided by 7000 French Protestants, chiefly cavalry, entered Hainault, and surprised the important city of Mons. Another corps under Count de Bergh entered the province of Overyssel, and seized Zutphen, Gorcum, and some smaller places. Alba was alarmed at these events, but more at the apprehension that it was not merely the French Protestants, but the French king, who had become the ally of Orange. He turned his attention, first of all, to the recapture of Mons, and after a siege of three months took it on capitulation, a division of the main army which was proceeding to raise the siege having been defeated. After the capture of Mons, Alba collected his forces, and led them to attack the city of Haerlem, in the province of Holland, as preparatory to the conquest of the other maritime positions. That place, defended chiefly by its citizens, made a noble resistance; but after a siege of seven months, in which the exertions and the sufferings of the inhabitants appear almost incredible, it surrendered, and was delivered over to the vengeance of the irritated and unfeeling Spaniards. In this siege, carried on in an aquatic district, and in the winter months, the besiegers suffered severely, especially as they were ill supplied with provisions. Their sufferings and their want of pay caused a mutiny after the capture, which paralyzed for a time the operations of Alba, whilst the Prince of Orange was carrying on the siege of Middleburg in Zealand, which was ably defended, and only surrendered after a siege of two years duration. The states of Holland and of Zealand had been assembled at Dort, where, notwithstanding the republican jealousy which prevailed, powers almost unlimited were conferred on the Prince of Orange, and a kind of government constructed to manage the affairs of these two provinces.

We have thus sketched the outline of events from the end of the year 1568 till the end of 1573, at which time the court of Spain had recalled Alba, who departed with enormous wealth, and the curses of all classes of the people, in January 1574. He was succeeded in the government by Don Louis de Zuniga of Requesens, but generally called by the latter name. When Requesens assumed the government, he found the affairs of it, in those parts still under the Spanish power, in a dreadful state of derangement. The people were universally disgusted, the army in a state of mutiny, and the finances absolutely exhausted. Though intrusted to adopt a milder system of government, and actually issuing an amnesty, he could not overcome the deep hatred to his country which the Flemings had conceived. He naturally followed the military plan which had been traced out by his predecessor. The Prince of Orange had carried on the siege of Middleburg nearly two years, and Requesens resolved to attempt its relief. His naval forces were collected, and a battle ensued, in which the Spanish fleet was defeated, and most of the ships taken, burned, or sunk. This occurred on the 19th of January 1574, and was followed by the capitulation of the city on the 19th of February. The garrison, the ecclesiastics, and such of the burghers as wished it, were allowed to proceed to Flanders. This treaty was the commencement of a milder treatment of prisoners on both sides, and henceforward the contest assumed a more humane form. The capture of Middleburg was important, as it decided the fate of the province of Zealand, which was soon rendered unassailable by the Spaniards, whose naval force was far inferior to that of the Prince of Orange. Requesens sent a corps of his army to attack a force under the command of Prince Henry of Nassau, over whom a victory was gained, on the 14th of April, near Nimeguen; but a mutiny immediately broke out amongst the Spaniards, and rendered the success of no value. When the mutinous spirit was somewhat allayed, the Spaniards besieged Alckmaer, but were received by the inhabitants with such resolution that they gave up the attack and concentrated their forces to besiege the city of Leyden. It was carried on with great vigour, and defended with skill and bravery; and after the besieged had for nearly six months endured all the horrors of famine and disease, by cutting some dikes the Spanish camp was covered with water, more than a thousand of the assailants were drowned, and on the 3d of October the siege was abandoned. This secured to the party of Orange the freedom of the province of Holland, as the capture of Middleburg had done that of Zealand. The Spaniards were thus expelled from every part of those states except the city of Amsterdam, of which they did not quit possession till four years afterwards.

After defeat or after victory the Spanish troops were equally accustomed to mutiny. The repulse before Leyden begot this spirit, which displayed itself by deposing their commander Don Sancho de Avila. They chose one of their own number as a leader, and carrying with them Don Sancho, bound hand and foot, proceeded towards Utrecht, where by plunder they boasted they would pay themselves the arrears owing to them, and they committed the greatest excesses on the small towns which they were able to seize upon. At length some money was paid to them, the mutiny was appeased, and Requesens led them to make attacks on some of those islands which compose the state of Zealand. These were all repulsed by Prince Louis; and Requesens, who had superintended the operations in person, at length abandoned all attempts. He was called to Brussels by a mutiny of the Spanish cavalry in that city; but on the day of his arrival he was attacked by a fever, which in a short time terminated in his death.

This brings the events down to the end of the year 1575, at which period an attempt at conciliation was made by the emperor of Germany. A congress was held at Breda, where an ambassador from his imperial majesty, the two brothers of the Prince of Orange, the pensioner of Holland, deputies from Zealand and Gelderland, and two ministers of the king of Spain, met; but nothing was agreed on, after three months spent in negotiation, as the preliminary question of religion could not be settled. The king would only admit of the Catholic faith, and the opposing parties as resolutely maintained that of the reformed church.

In 1576 the Prince of Orange succeeded in the plan he had long formed, of forming such a union between the two states of Holland and Zealand as should concentrate their efforts for the common defence, by placing in his hands, under the name of regent for the king, the whole executive power. This arrangement, concluded in April, was announced to all the cities, and accepted by them; and the prince having taken the oath of fidelity to the privileges of the states, assumed the government, and arranged the administration with judgment, despatch, and economy.

At the same time, within the provinces still belonging to Spain, the death of the governor created the greatest confusion and disturbance. The council of state, consisting chiefly of Flemings, assumed the administration, and, as soon as an answer to their communications could be received from Madrid, were confirmed in that power, but only *ad interim*, until Don Juan of Austria, who was named governor, should arrive. Though composed of only nine or ten members, this council soon became divided into factions, which thwarted each other; they were without pecuniary resources, and could take no measures to remove the difficulty. The consequence of this was, that the Spanish troops, being unpaid, broke into furious mutinies, and, with the pride of their nation, rejected the authority of the council, deposed their officers, chose one of their own number, who was called *Eletto*, indulged everywhere in the most unlimited plunder, and committed the most atrocious barbarities. The movements made by these troops alarmed all the inhabitants of the cities, so that even in Brussels itself the council could scarcely have been in safety without yielding to the impulse of indignation which was displayed by all orders of the citizens. The mutinous troops had taken by storm the fortified city of Alost, between Ghent and Brussels, when the council, on the 29th of July, issued a placard denouncing the Spaniards as rebels to their king and the country. They were depicted as mutinous traitors, and the people of the Netherlands were called upon to exterminate them wherever they were to be found; they were also forbidden to supply them with provisions, and commanded to remove out of their way all money and other valuable effects.

The insurgent army at Alost alarmed the city of Ghent, where the inhabitants had armed themselves; but the castle which commanded the town was held by some Spanish troops, who were in connection with the mutinous army. It was of importance to take the castle; and a party in that place, where the Prince of Orange had numerous secret friends, made application to him for assistance. He, who had foreseen the event and was prepared to meet it, despatched from Zealand eight bodies of infantry, amounting to about 3000 men, with seventeen pieces of artillery, under the command of Colonel Temple, an English officer in the service of the states, who entered the city on the 26th of September, and having formed the siege of the castle, caused it to surrender on the 11th of November.

The possession of Ghent was the signal for a general movement amongst the Flemings. In spite of the orders of the king positively forbidding it, the states assembled in each province, and the feeble and divided council gave way before them; and thus the power was vested in a body, who confined some, displaced others, of the council, and changed the government into that republican form which the seven provinces that ultimately obtained their independence afterwards adopted. The king's name was used, but his power was for the time abolished. The new government sent its envoys to the several courts to implore assistance. The emperor and some other princes answered with cordiality, and offered their mediation to effect a general pacification. The king of France (Henry III.) spoke plainly, and showed good will, but said that his opponents, the Leaguists, supported by the pope and the king of Spain, had so embarrassed his affairs as to deprive him of the power of rendering them any assistance. Queen Elizabeth of England received the envoy, Baron Sweveghau, with much distinction. She granted to the states a loan of one hundred thousand pounds sterling, of which forty thousand were immediately paid in uncoined silver, and the remainder was made payable at Brussels by her ambassador. The cities of Ghent, Bruges, and Nieuport were securities for the money; and the states agreed neither to make truce nor peace with Spain without England being comprehended in it. The other conditions were, that the English merchants should be restored to the privileges which they had enjoyed before the troubles, and that the subjects of England who had been banished should not be protected within the territories of the states.

A treaty was soon concluded at Ghent, and ratified at Brussels, between the states on one part, and the Prince of Orange in the name of the states of Holland and Zealand on the other. The chief stipulations were, that the contracting parties should unite to drive all Spaniards from their countries, and then assemble as in states-general before 1555, to regulate the affairs of religion, of the fortresses, and the ships of war; that no attempts should be made against the Catholic religion; that all the ordonnances issued by the Duke of Alba should be suspended till they were confirmed by the states; and that in the mean time the Prince of Orange should retain his power as stadtholder of Holland and Zealand. This treaty was signed in the name of the king, and in a short time was acceded to by those other provinces not represented in the states assembled at Brussels.

Whilst these transactions were in progress, the Spanish troops, though diminished in number by their own excesses and the vengeance of the country people, continued in the same mutinous condition. One division of them took Maestricht by storm, and there perpetrated the most abominable injuries to persons and property. Two other divisions, one from Alost and the other from Zealand, united to seize on the rich city of Antwerp; and with them joined the portion of the garrison of the citadel of Antwerp which had cut its way through the besieging army. The citadel was in possession of the Spaniards; and as soon as the rest of the mutineers had been received into it, they stormed the city, which, though bravely defended, was ultimately overcome, a great part of it being burned in the conflict, and what remained, as well as the persons of the inhabitants, became a prey to the infuriated and merciless mutineers. Destruction was thus inflicted on the most flourishing commercial city of Europe, from the effects of which it has never since recovered. The destruction of that city was, however, one of the causes, and not an inconsiderable one, of the rapid progress in foreign commerce which was made in Holland during the subsequent prosecution of the long protracted war, and supplied much of the pecuniary means by which that war was maintained.

Don Juan of Austria, who had been appointed to the government of the Netherlands on the death of Requesens, was a natural son of the Emperor Charles V. who had ordered him to be educated in secrecy, but suitably, according to a respectable station in life. The history of his birth had been concealed from him until he had arrived at maturity, when King Philip himself unexpectedly revealed it, and acknowledged him as his brother. At an early age he had been employed against the Moors of Granada, and had by his successful exertions gained great applause; but the chief ground of his high reputation arose from the naval victory of Lepanto gained over the Turks, when he commanded the united fleets of the Christian world.

When nominated to the command he was residing at Milan, but instantly departed from thence to Spain, where he received his instructions from the king. He was directed to treat the Netherlands with great mildness at first, but to commit himself to nothing definitive, and on no account to give up any of that unlimited power which the king was firmly resolved to exercise. It was commonly believed that the king gave him an assurance, if he succeeded in restoring the Netherlands to submission, that he should be supplied with forces to land in England, where he should release Mary Stuart from her prison, place her on the throne of Elizabeth, and by a marriage with her become monarch of the British islands. Don Juan rode post through France, at that time in a state of confusion, in the disguise of a servant to one of the nobles who accompanied him, and at length reached Luxembourg on the day on which the mutinous army of the Spaniards had stormed the city of Antwerp. On his arrival there, the disastrous state of the affairs of Spain, which has already been described, seems to have left him no other alternative, after announcing his arrival to the states, than that of acquiescence in the decisions of that body, conjointly with the Prince of Orange. He accordingly gave his assent to the pacification of Ghent, and to that article of it which stipulated the removal of all foreign troops from the country of the Netherlands. Some confidence was thus gained with the states-general, but none with the Prince of Orange, with whom Don Juan had opened a correspondence of an apparently amicable and confidential nature. The troops were in appearance disbanded, or marched away. The Spaniards moved slowly towards Italy, from whence they could be recruited. Some of the auxiliaries were said to have been lent to the Leaguists in France, so as to be within call when needed. In a few months, which were passed in conciliatory measures, Don Juan, rather by fraud than by force, obtained possession of the strong castle of Namur, in the month of July, and established his court in that city, where he soon began to collect troops. This caused an alarm in the states, and they also began to collect their forces. The Prince of Orange was invited to repair to Brussels, in order to concert with the states the measures requisite for the defence of their freedom. Negotiations were begun with insincerity on all sides, for neither could trust to the assurances and engagements of the other. The Prince of Orange, who had entered Brussels on the 23d of September, was consulted on these negotiations, and was in some sense a party to them; though he foresaw, from the very moment of Don Juan's arrival, that no secure treaty could be formed, and that the sword must decide the issue. The states, at the suggestion of the Prince of Orange, had decreed the demolition of those fortresses which commanded the cities, especially those of Antwerp, Ghent, Utrecht, Groningen, and Lisle. This was the signal for hostilities. Don Juan had recalled the troops on the march for Italy, and those lent to the party of the League in France. The Prince of Parma brought other reinforcements; and thus Don Juan found himself at the head of an army of nearly 20,000 at the end of the year. The army of the states consisted of nearly equal numbers. They were, however, inferior in discipline and in good officers to the forces opposed to them. The two armies were in presence of each other in December. The army of the Spaniards had been so secretly collected, that the states believed that their own troops much outnumbered them, and from this impression gave orders for the attack. On the 31st of January a bloody conflict took place at Gembloux, near to Namur, in which the Spanish force was victorious. The army of the states suffered very severely; their general, Goignies, with many of his men, were made prisoners, and the remnant retreated towards Brussels. The Prince of Orange and states removed from thence to Antwerp. Don Juan, instead of pursuing them, followed up his success by capturing the smaller fortified towns. In the course of the year 1778, he had taken Louvain, Tirlemont, Bovines, Diest, Nivelles, and some smaller places. These conquests were effected by detachments, whilst his main body was encamped near Namur. But he was taken ill in September, and died on the 1st of October 1578. The cause was probably a pestilential fever, but, according to the custom of that age, was most commonly attributed to poison. On his death-bed Don Juan nominated as his successor his nephew the Duke of Parma, who had recently joined him. He was a young man of highly-estimated talent, the son of that duchess who had long been the regent of the Netherlands, and under whom the troubles had commenced.

When the Prince of Orange had retired to Antwerp, he clearly perceived that, from the nature of the country, and the confidence placed in him by the people, he could preserve a secure asylum for liberty in Holland. His means did not extend to the other provinces of the Netherlands with the same commanding effect. He therefore turned his chief attention to that which, with a concentration of his means and exertions, could with most probability of success be attained.

As the ten provinces were at length all brought under subjection to Spain, and finally were transferred to the house of Austria, the transactions relating to them do not appropriately belong to the history of Holland, and will therefore be only so far noticed here as regards their connection with that country.

It was the policy of the Prince of Orange to keep alive the spirit of opposition which still existed in Flanders, because it gave employment to the troops of the Duke of Parma, and time to the inhabitants of the United Independent Provinces to prepare for that firm defence which must be the only means of securing their ultimate independence. Those states also gained much in another view. Holland was a secure asylum, and the inhabitants of the other ten provinces found refuge there, when neither tranquillity nor security could be enjoyed at home. At this period, many of the richest of the traders once more removed their families and their property to the cities and towns of Holland and Zealand. The ruins of the commerce of Antwerp were collected in Holland and Amsterdam, though the last place, from which the Spaniards had been driven out in 1578, received the greater share of it.

Whilst Flanders was torn to pieces by the contest between the troops of the Duke of Parma and those raised by the states, the United Provinces assumed in their temporary tranquillity a more imposing aspect. The important province of Utrecht joined the party of Holland, Zealand, and Friesland. The war had been carried on against the king of Spain without explicitly renouncing allegiance to him. But after the accession of Utrecht, the declaration of their independence of the authority of that monarch was promulgated. This gave confidence to the inhabitants, and admitted them to treat as sovereign states with any of the other governments of Europe. To these four provinces the three small ones of Zutphen, Overyssel, and Groningen were added, and thus formed a compact and easily defended district. They assumed for their arms a bundle of seven arrows, with the motto, *Concordia res parvæ crescunt, discordia maximæ dilabuntur.*

We pass over the endeavours made to establish the Duke of Anjou, brother of the king of France, as the governor, the wars subsequent upon it, and the attempts made to assassinate the Prince of Orange, because they belong rather to the history of Flanders than to that of Holland. It may, however, be proper to remark, that in the intercourse between that duke and the prince, the latter favoured the pretensions of the former; but he seems to have done it without any prospect, perhaps without any hope, that it would do more than operate as a diversion in favour of the seven United Provinces, to whom his chief regards were always directed.

From the death of Don Juan of Austria, at the end of the year 1578, to July 1584, the state of Flanders arrested all the efforts which Spain could make to attack Holland; and the inhabitants availed themselves of it to extend their commerce, to increase their ships, to economize their resources, to accumulate warlike stores, and to organize and discipline the whole of the male population. Spain was too much engaged with other objects to direct any strenuous operations against Holland, calculating that if she could subdue the ten larger and more populous provinces, the submission of the other seven would either necessarily follow, or might be easily enforced. Besides, she was at that time making preparations for the enormous naval force called the Armada, with which she calculated on conquering England, and thought that by that achievement Holland would fall under her power.

The intense personal hatred which existed between Philip of Spain and the Prince of Orange gave birth to the most virulent and threatening manifestoes, which were printed, diffused, and read throughout Europe; and the king even made it generally known, that whoever should succeed in assassinating the prince, should receive a reward of 80,000 ducats, be made a commander of the order of St Jago, and obtain patents of nobility. These offers, stimulated also by religious fanaticism, induced many individuals to arm themselves for the horrid deed. One of them, Geerardt, a Burgundian, gained access to the prince by means of letters from Count Mansfeldt, and, as he was passing from his dinner table to another apartment, shot him with a pistol concealed under his cloak, which discharged three balls into the breast of his victim. The prince fell, exclaiming, "I am wounded. Lord, have mercy on me, and on this poor people!" He then immediately expired. The assassin was taken and executed. The recompense for the detestable deed was subsequently made to his family; for, in the register of the court of Madrid of the 4th March 1589, patents of nobility are entered as conferred on his brothers and sisters, who are described as bearing that relation to Geerardt, a tyrannicide.

This tragical event occurred on the 10th of July 1584, at Delft, where the states of the seven provinces were then assembled. It inspired courage rather than despair among the patriots of Holland. The eldest son of the prince was a prisoner in Madrid, where he had been detained from the commencement of the troubles. His son Prince Maurice was instantly invested with all the power of his parent, though only eighteen years of age; and Count Hohenlohe was appointed with the character of his lieutenant.

The Dutch attempted to enter into negotiations with those powerful princes who were hostile to Spain. The application to France was made at a time when the power of the confederation of the League was so formidable as to preclude the prospect of any aid. Henry III. received the deputies with respect, but recommended them to make application to Elizabeth of England. Offers were made to her of the sovereignty of the Netherlands, which she declined; but she made a treaty stipulating to furnish six thousand troops to be maintained by her, and was to have Flushing, the Brielle, and the castle of Rammekins, as pledges. Leicester, her favourite, was appointed to the command, and was to have concurrent power with two members chosen by the states in all military affairs, but was not to intermeddle in the civil transactions.

The imprudence or ambition of Leicester gave much umbrage to the states, and his presence became rather injurious than beneficial to them. The threatening danger from the Spanish Armada, and some degree of disapproval of the conduct of Leicester, induced the queen to recall him and the greater part of the force. The conduct of Leicester had produced the loss of Zutphen and Deventer; but, after the defeat of the Armada, fresh troops were sent from England, and these having drawn the Spaniards towards Ostend, in which was an English garrison, Prince Maurice was enabled to recapture those places. The celebrated siege of Antwerp, though scarcely an operation in which the Dutch were engaged, may be here noticed. It was a long and heavy labour of seven months, carried on by the Duke of Parma in person. During its progress the most extraordinary bravery and skill was displayed by the assailants and the defenders; but the place finally surrendered, and the remains of its commerce were transferred to Amsterdam. After the recapture of Zutphen and Deventer, Prince Maurice, whose forces had been recruited, threatened Dunkirk and Nieuport, and, after a short but vigorous bombardment, captured the important city of Nimeguen, and other towns in that quarter; and these operations closed the campaign of 1592. The Duke of Parma had advanced with an army into France, and left the management of the war in the Netherlands to Count Mansfeldt.

In the beginning of 1593, Mansfeldt issued edicts forbidding all communication with the revolted and now *de facto* independent provinces, and declaring that no quarter would be given to any who did not join him. Such threats were however of no avail, for Prince Maurice having collected his forces, attacked the strong city of Gertruydenburg; and though Mansfeldt, at the head of 12,000 foot and 3000 horse, attempted to raise the siege, he was foiled. The place surrendered on the 23d of June, after suffering the extreme of famine.

The Spaniards were still in possession of the city of Groningen, where Verdugo, an Italian, commanded. The chief operations of the year 1594 were in that quarter. Much time was passed in able manœuvres between Prince Maurice and that general. But the prince having succeeded in cutting off the communication between Groningen and Germany, that city was compelled to surrender in July. The many repulses which the Spaniards had received, and the want of pay, produced a mutiny, and the soldiers threatened to indemnify themselves by the plunder of Brussels, and other towns in the ten provinces under the crown of Spain. The mutineers were in communication with Prince Maurice, but he declined taking them into his service, though the mutiny was turned by him to the benefit of his country.

In the year 1595 a general discontent against their Spanish masters spread itself in the ancient provinces. It was fomented by the Flemish nobility, who, in an assembly convened at Brussels, demanded peace. This affair turned out advantageous to the seven provinces, where Prince Maurice and the states-general were occupied in negotiations both with England and with France, with both of which countries treaties were concluded, in which the Hollanders engaged to supply them with naval forces, some of which assisted Sir Walter Raleigh in his successful attack upon Cadiz.

Philip of Spain, now advanced in years, having become disgusted with the cares of government, his Flemish provinces were placed under the management of the Archduke Albert of Austria. He had under his command an army of 30,000 men, with which he took Calais, and then rather turned his forces towards France than towards the new republicans. The Dutch had by this time grown up into a great naval power. They are said to have had on board of their shipping more than 70,000 seamen. The bloody wars in which they had been engaged seemed to have increased their wealth and their spirit of commercial enterprise. Even their enemy Philip connived at their carrying on a very beneficial trade with his subjects in Spain and Portugal, whilst their cruisers covered the seas, and made numerous captures of the trading ships of those very subjects.

The earnest desire to attain naval superiority which animated the Dutch, was accompanied with a correspondent neglect of their land forces. The arms of France, however, acted as a diversion in their favour, and enabled Prince Maurice in 1597 to defeat one of Albert's generals, and, in consequence thereof, to capture Turnhout, near Antwerp; and in the end of the year, several other towns in that quarter submitted to the states-general. In the same year, negotiations for peace were attempted, under the mediation of the emperor of Germany and the king of Denmark; but the states refused to treat till the king of Spain should acknowledge their independence. The peace of Vervins was concluded between Spain and Henry IV. of France, to the great disgust of Elizabeth and of the United States, who thereby were brought into more intimate alliance.

The commerce of the states was now much augmented. One of their citizens, Balthasar Monchuen, besides trading extensively to India, formed settlements upon the coast of Africa and upon the island of St Thomas. Other merchants sent their ships to the South Seas, through the Straits of Magellan, in the hope of discovering a passage to Japan and China. Companies were formed which sent large ships to the East and West Indies. The trade in the Mediterranean was extensive and lucrative; but, above all, their fisheries on the coasts of England became a mine of wealth.

Though with inadequate force, Prince Maurice, in the winter of 1599, surprised Emmerich on the Rhine, and projected the transference of the seat of war to Germany; whilst Mendoza, the Spanish general, was opposed to him, and invested Bommel; and, though an indecisive battle was fought, Maurice delivered that fortress from the besiegers, and secured his own conquest. After this, party-spirit appeared in Holland, with sufficient fervour to lead to the reduction of the army; but, fortunately for that country, the Spanish troops were so mutinously disposed, that they were unable to take advantage of this diminution.

About the end of 1600, the states were roused to make greater land preparations, and their army under Prince Maurice, in conjunction with an auxiliary English force under Sir Francis Vere, gained the decisive victory of Nieuport, in which the Spaniards lost 5000 men, whilst the loss of the allied army did not exceed 1500, of whom 800 were English. Though Nieuport was invested, Maurice was compelled to raise the siege, when the armies went into winter-quarters. About the end of 1601, some attempts at negotiations for peace were made, but, like those of the former years, they were soon suspended.

The chief military event of the three following years was the siege of Ostend, in which Vere had at first the command; but in the course of the long operations he was relieved, and joined the prince with his troops, who were replaced by the soldiers of the states. The whole attention of Europe was engrossed by the great display of military art in and before Ostend. Spinola the Spanish general was one of the first of the military geniuses of that age, and Vandernoot, who defended the place, was his equal. With an immense loss of life and expenditure of money, after a siege of more than three years' duration, the place was surrendered by capitulation on the 20th of September 1604.

The death of Queen Elizabeth in March 1603, and the accession of James to the throne of England, gave a new turn to affairs. The temper of that monarch was decidedly pacific, and though at first he in some degree adhered to the alliance with the states, his assistance was small, and in some of the transactions rather adverse. The war was continued between the armies commanded on one side by Prince Maurice and on the other by Spinola, but both were so cramped in their operations by the parsimony or the poverty of their respective governments, that no decisive event occurred. The naval war was more effective. The fleets of Spain from the East and West Indies were intercepted by the Dutch. Tremendous conflicts were carried on, by which some of the vessels loaded with treasure from the New World fell into the hands of the republicans; but a much larger portion of the vessels which contained it were either burned or sunk. The failure of remittances so impoverished the king of Spain that he became disposed to treat for peace. The negotiation began in the early part of the year 1607. At first the required acknowledgment of independence suspended it, but in the month of April 1607 Spain gave way, and a suspension of arms for eight months was agreed upon, without any communication of it having been made to the kings either of England or of France. When the eight months had expired, no treaty had been concluded; and, though no hostile movements were made by land, the captures of the Dutch at sea were continued during the prosecution of the treaty. At length a truce for twelve years was agreed to in April 1609. A general amnesty on both sides was stipulated, and a freedom of trade by sea and land, including both the Indies, was agreed to.

This treaty, though only concluded for a fixed period, was yet a termination of the war as between the king of Spain and the seven United Provinces. The states had no sooner attained peace and independence, than they intermeddled with the affairs of the other sovereign states of Europe, and became involved in hostilities with Germany, in which Prince Maurice, on a disputed succession to the duchies of Cleves and Juliers, took the latter city, and garrisoned it. But the Germans having soon afterwards taken Wesel, a termination was put to the contest by the mediation of England and France.

Almost as soon as the states had concluded a general peace, internal dissensions arose. These were maintained by the nature of their constitution, which conferred on each individual state an independent sovereign authority. The first occasion arose from a theological difference of opinion on a topic, of all others, the most inscrutable by the human faculties. The Protestants had imbibed their opinions from Calvin, and had generally adopted his doctrine of predestination. The professors of the universities had advocated that opinion, when Arminius, a native of Holland, was appointed to the divinity chair of Leyden, and taught the opposite opinion of the freedom of the human will. He thus became the head of one sect, whilst a Dr Gomarus, another professor, became the leader of the Calvinistic sect. Theological discussions soon created political parties. Prince Maurice had imbibed the opinions of Arminius, but finding the clergy and the great body of the common people attached to those of Gomarus, he, without regarding the private opinions he held, placed himself at the head of the Gomarists. Barneveldt, the chief civil man in the union, was in opinion a Calvinist; but seeing the nobility and the better educated part of the people supported the system of the Arminians, he became the chief of that party. The acrimony and bitterness with which the contest was carried on soon rendered it of a mixed character, combining religion and politics. Each city possessing within itself independent powers, punished or protected either the Arminians or the Gomarists. Those two eminent scholars Grotius and Vossius defended Arminianism, whilst the synod of Dort, assisted by King James of England and the Archbishop of Canterbury, for a short time maintained the opposite side in the controversy. Prince Maurice, by his influence with the common people, and from being at the head of the army, was enabled in many of the cities to change the magistrates; and when he could not effect that purpose, as at Utrecht, he called in the troops to their assistance. Barneveldt and his party proposed a general toleration of all opinions, and presented a remonstrance to that effect; a proceeding which changed the names, but not the characters, of the party. The Arminians were called Remonstrants, and the Calvinists Anti-Remonstrants, names which have been continued to this day. The party of Maurice, consisting chiefly of the populace of the cities, and their clergy, was ready to tolerate Jews, Mahommedans, and infidels, but would not consent to grant similar toleration to the Remonstrants.

It became evident that the prince was aiming at establishing for himself and his family an hereditary sovereignty over the states; whilst Barneveldt and the higher classes, on the other hand, eager to perpetuate the liberties of their country, formed connections with the court of France, and thence obtained the name of the Louvestein faction, which has been continued amongst the opposers of the absolute power of the house of Orange to the present time. But the Orange party acquired such superiority that Maurice was enabled to seize and imprison the venerable Barneveldt and the learned Grotius, the former of whom, after an infamous trial, when the judges were threatened with death if they did not pronounce the popular sentence, was condemned to death, and beheaded at the Hague on the 13th of May 1619. As the benefactor of his country, he died with the regret of the wise and good of his own time, and has been viewed by succeeding ages as one of the chief authors of the victories, the prosperity, and the liberties of his country. Grotius was still a prisoner, probably not a very strict one. He was allowed the use of books, which passed in a large chest unexamined, and in that chest he was concealed and carried away. He escaped to France, and passed the remainder of his days in an honourable, useful, and upright manner.

The truce was now drawing to a close. The interval which the Dutch had enjoyed had been employed by them, in spite of their internal dissensions, in the most profitable manner. They had prodigiously extended their maritime operations, having been much benefited by the languor of James I. of England, and the ruined state of the marine of Spain. Their ships gave laws from the Baltic to the Levant. They had forced a trade with the Spanish possessions in the western world and in the East Indies; and, besides some smaller acquisitions, they had founded Batavia in the island of Java, which soon became the emporium of the trade of the eastern world.

Philip of Spain died in 1621, just at the time when the truce between him and the Hollanders had expired. The greater progress the Dutch had made in prosperity and power, the more worthy objects of his ambition did he deem them, whom he still viewed as his rebellious subjects. He had instructed his ambassador to propose such terms of peace as were sure to be rejected, which in fact they were, in the most contemptuous manner. But Prince Maurice was not well supported by the states on land. The operations were not of great moment. The Spaniards under Spinola took Juliers, but were repulsed in an attack upon Haerlem. Maurice made an effort to seize upon Antwerp, which failed; and he returned to the Hague, where an attempt was made by a grandson of Barneveldt and some Arminians to assassinate him. This, though it failed, gave great strength and violence to the Gomarists, and they were most unrelenting in their cruel punishments. The rack and the axe were in constant employment, and to be known as an Arminian was deemed sufficient cause for their infliction. The war by land against the Dutch was continued by Spinola, on the side of Belgium; and though he could not prevent them from recapturing Juliers, and taking Cleves, he collected such a force as enabled him to besiege Breda, which was commanded by an English colonel, Morgan. It was an important place, strongly fortified, and of great interest to Prince Maurice, because it formed the centre of his patrimonial estates. It was ably defended, and during the ten months the siege lasted, the loss of the Spaniards was enormous. They however ultimately succeeded, and a capitulation was signed on the 6th of June 1625.

During these operations, Prince Maurice died in the eighty-eighth year of his age. Ambition alone, which had caused his severity towards the Arminians, prevented him from being the most amiable, as he was one of the ablest men of the age in which he lived. About the same period King James of England died, and was succeeded by the unfortunate Charles I. Prince Henry of Nassau was the successor of his brother, as governor of the states of Holland, Zealand, Guelderland, Utrecht, and Overyssel. He continued the military operations against Spinola, but, after the surrender of Breda neither party could boast of having gained much advnatage.

The naval operations in some degree compensated for the languor which prevailed on land. The Dutch sent an expedition to the South Sea, which attacked the Spanish settlements in Peru with much success; and at length they also conquered St Salvador and other parts of Brazil, but were soon afterwards obliged to abandon the acquisitions they had made. In the interior the religious dissensions began to revive. Henry prince of Orange was thought to be less rigid towards the Arminians, in other words, more favourable to them, than suited the principles of the Gomarists. This caused such a commotion as threatened a civil war, which was only prevented by the necessity of union against the common enemy. The Dutch fleet had joined that of France, with which power they were in alliance; and this united force was attacked by the ships of the French Protestants under Soubise. They were defeated, and the Dutch admiral's ship was blown up, with himself and his crew. This caused the greatest joy among the common people in Holland, who detested the conduct of their chiefs; and in the city of Amsterdam their houses were pillaged, and their persons grossly insulted.

The threatening appearance of the thirty years' war in Germany induced the states to increase their land forces in 1626; but during that and the following year only indecisive operations occurred, as the imperial general, Tilly, did not make the expected attack on their frontier towns. The Spaniards made Dunkirk the place for collecting a great number of privateers, by which the Dutch commerce was much annoyed, and many bankruptcies occasioned amongst the merchants of Amsterdam. This induced the Dutch to blockade that port so closely that the system was checked, and in 1628 their East and West India fleets all arrived in safety, loaded with valuable cargoes belonging to the two great commercial companies which had grown up in Holland.

During the same year the fleets of Holland were remarkably successful against Spain. Peter Adrien captured twelve of the largest West Indiamen in the Bay of Honduras. Admiral Heine had still greater success, having a larger force, and in the Bay of All Saints captured so many ships laden with sugar, that the quantity, when brought to Holland, lowered the price of that commodity in all parts of Europe. He then with thirty ships intercepted the Spanish plate fleet, and, after ravaging the coasts of Spain and Portugal, returned with prizes valued at more than fifteen millions of livres. But the state of Holland was far from being tranquil. Fresh umbrage was taken by the populace at the Prince of Orange, because he had appointed some of the Arminians as magistrates, and the people of Amsterdam refused to obey them. This, with tumults amongst the seamen on account of the inadequate distribution of the prize money, caused serious commotions, which were with difficulty and some sacrifices of life put down.

The successes of the Dutch at sea had a favourable influence on the land operations of the following year. Want of pay had produced mutiny in the Spanish army. The Dutch vigour was again awakened, and the Prince of Orange furnished with a powerful army. An active campaign, in which Turenne, Montecuculli, and some other of the most celebrated warriors of the age, bore a part, was closed, by the capture of Bois-le-Duc on one side, and of Wesel on the other frontier of Holland, in spite of all the efforts of the Spaniards to raise the sieges of these places. In the year 1630 the Spaniards renewed their efforts to defend the places they held on the German frontier, but were so unfortunate that, after fruitless attempts to organise a German Catholic confederacy against Holland, they were induced to enter into a negotiation for the conclusion of a truce during thirty-four years. But this negotiation was rendered ineffectual, principally by the intrigues and the influence of the French minister Richelieu, who had by this time formed a strong party in Holland, in opposition to that of the Prince of Orange; a party which continued up to the present age, and to the existence of which may be attributed the enmity displayed by the successive heads of that family to the French government. After the rupture of the negotiations, John of Nassau, with a force, aided by some of the German Catholic princes, of troops and water craft, made the attempt to separate Zealand from Holland. The expedition was met by the Dutch gun-boats; a terrible conflict ensued; the Spanish flotilla was either sunk or captured; and 5000 men were made prisoners, who entered immediately into the service of Holland. This blow was followed up by the Prince of Orange, with his whole force, augmented by the junction of 12,000 Swedes of the army of Gustavus Adolphus, with whom the states had made a treaty, by an attack upon Maestricht, which at length capitulated, as did also the fortified city of Rheneberg on the Rhine, by which Holland became secure from all invasion on the side of Germany. At this time attempts were again made towards negotiation; but the interference of the Austrian general Pappenheim, who had garrisoned some of the towns belonging to Spain, prevented, by his claims, any treaty from being brought to a pacific conclusion.

The Dutch army for the campaign of 1633 was more powerful than at any former period, and was thought sufficiently strong to have completed, with a general of such talents as the prince, the entire conquest of Spanish Brabant. He took the field for that purpose, but the excessive rains of that season, the great inundations, the sickness which prevailed in the army, the scarcity of provisions, and other inconveniences, compelled him to put his army into winter-quarters at a very early period, without having effected or scarcely attempted any object of importance. The year 1634 passed over with no memorable displays of hostile movements. The death of Gustavus Adolphus in the midst of the vast operations in Germany, of which he was the animating soul, caused so many and various negotiations, that the whole of Europe had its attention directed to diplomatic discussions. The war between the Spaniards and the Dutch languished in the Netherlands, though it was carried on at sea much to the benefit of the latter party. In this year, 1635, a partition treaty was entered into with France by the states, contrary to the will of the Prince of Orange, and their ally the king of England, by which the provinces of Luxembourg, Namur, Courtray, Hainault, Artois, and Flanders, were to be transferred to the king of France, and those of Brabant, Guelderland, and the districts of Waes, Mechlin, and the rest of Flanders, to the United States. In pursuance of the objects of this treaty, the fleets of France and Holland were united together; but preparations from England to place her marine in opposition induced them to return to their respective ports. The attempts by land were equally ineffectual. France marched an army of 20,000 foot and 7000 horse into Brabant, and the states had equipped one of nearly equal force. These united troops were to be commanded by the Prince of Orange; but whether that commander, from being averse to the service, neglected to accomplish its objects, or whether the arrogance and barbarities of the French disgusted their allies, such dissensions arose between the officers, that no movements proved beneficial, and the campaign was closed at an early period. The Dutch withdrew to their own country, and the French went into winter-quarters at Ruremond, where it is said more than 6000 of them died, from want and disease. Cardinal Richelieu and the Prince of Orange cherished a mutual animosity, which, though it neutralised their land operations, did not cause a rupture of the alliance that had been formed. The Dutch were successful by sea, where they defeated a Spanish squadron near Dunkirk; and having blockaded that port, secured a safe return to their numerous trading ships from the East and West Indies. In the same year they fitted out an expedition, with the design of extending their power in Brazil. This force, under the command of Prince Maurice of Nassau, consisted of thirty-two ships, with 2700 land forces, and arrived safely at its destination.

The year 1637 was distinguished by the efforts made to capture Breda, which was occupied by a Spanish force under Fourben, a brave and skilful officer. It was invested by the Prince of Orange, and several attempts to relieve it failed, so that after a long siege it capitulated, but not till the beginning of the year 1638. In that year a great project was formed by the Prince of Orange for the capture of Antwerp. It was well designed, but failed from unforeseen circumstances, such as often occur in operations combined of marine and of land forces.

The campaign of 1639 was planned by the Spaniards on a gigantic scheme, but was chiefly directed to naval objects. The Dutch admiral Van Tromp attacked a squadron of ten large men of war, near Gravelines, on the 18th of February. The fight was long and obstinate, but ended in the total defeat of the Spaniards. Their admiral, with three of the largest ships, was taken prisoner; the vice-admiral's ship was burned by the crew, and four of his division were captured; and their loss in men exceeded 2000. Notwithstanding this disaster, the Spaniards equipped a tremendous force under the command of D'Oquendo, consisting of eighty-seven large ships and numerous transports, with 20,000 land forces on board. A junction was formed of the two divisions, one from Cadiz and the other from Corunna. Van Tromp met and engaged this force, sunk the ship which bore the admiral's flag, and took four of the others, but was prevented by a fog from following up his success, whilst from the same cause the Spaniards took refuge in the Downs, where there was an English fleet to protect them. Van Tromp having received reinforcements under Evertzen, and, along with these, orders to renew the battle, desired the English fleet to withdraw; intimating, that if that request was not complied with, his orders were to fight both. Pennington, the English admiral, had doubts of the fidelity of his people, and no confidence in the Spaniards, who were ill disciplined and badly equipped. He therefore declared for a neutrality, but stated that he would join the fleet which should be attacked. D'Oquendo had been advised to withdraw, but it was no longer in his power to do so. Pennington, under pretence that the Spaniards had violated the neutrality, withdrew his protection. Van Tromp then began the attack, and the Spaniards were totally defeated. Fourteen Spanish ships of war were destroyed, amongst which was the Teresa of a hundred guns, with eight hundred men. The vice-admiral of Spain and the admiral of Galicia shared the same fate; sixteen large ships were taken, with 4500 prisoners; fourteen were wrecked between Boulogne and Calais, and the remainder were saved by the interposition of the English. Of the whole armament, only eight ships under D'Oquendo reached Dunkirk in safety. The Spanish loss in killed exceeded 8000 men. Whilst these naval triumphs were achieving in Europe, the Dutch were equally successful in the operations against the Spaniards in Brazil. Their admiral Count de la Torre had been dispatched from Spain with forty-six large ships and a numerous body of troops, many of whom died on the passage, and the others arrived in a sickly state. The Dutch fleet consisted only of forty-one ships, mostly inferior in size to those of their adversaries, but well disciplined, and commanded by two admirals of great bravery and skill, Loof and Huggins. The Spanish fleet previously in Brazil joined that under De la Torre, and they thus amounted to ninety-four ships. An action took place which lasted during several days. Loof was killed at the commencement, but Huggins at length gained a complete victory, in which the Spaniards lost twelve of their largest ships, and 4000 men, whilst the casualties in the Dutch fleet did not exceed one hundred. Disease still further reduced the Spanish force, and thus left Prince Maurice nearly master of that country. The prince then accomplished the conquest of Maranham, and despatched an expedition to the shores of Africa under Admiral Jol, who captured Congo, the island of St Thomas, and the other establishments which the Portuguese had formed on that coast.

At this period Portugal revolted from Spain, and, under the house of Braganza, declared itself an independent kingdom. The new king, John IV., concluded with the Dutch a treaty for a truce of ten years, in all the dominions of both countries, which, however, the latter are accused of having disregarded as far as related to Japan, whence they drove away the Portuguese, and secured for themselves the exclusive trade. The narrative of the transactions in Brazil is given in another part of this work, under that article; and, referring to it (vol. v. part i. page 191), we only add that it was finally abandoned by the Dutch in 1654.

The war between the states and their ally the king of France was continued, but with no great vigour. The jealousy of the Prince of Orange was increased by the discovery of the disinclination of Cardinal Mazarin, the successor of Richelieu, to his capture of Antwerp. He succeeded however in taking Hulst and Lillo, and thus secured a powerful barrier on the Flanders frontier. The negotiations for a general pacification were begun in 1642, and did not close till October 1648, when the celebrated treaty of Westphalia was signed at Munster and Osnaburg. In the first of these years, the treaty between France and Holland was renewed, but was scarcely in activity, as all the military operations of the several powers were in some measure, though not wholly, suspended, except that the Dutch availed themselves of the naval superiority they had acquired, by annoying the Spaniards in every quarter of the world.

Towards the close of the negotiations in Westphalia, the Prince of Orange died, in his sixty-seventh year, and was succeeded in his dignities by his son, William II. The states, regardless of their engagements with France, and in spite of the obstacles interposed by the French ambassador at Munster, entered into a separate treaty with Spain. This treaty was speedily ratified, and its terms formed a part of the general pacification of Europe. The king of Spain acknowledged the independence and sovereignty of the states, and a clause of *uti possidetis* in all parts of the world formed one of the articles. From the peace of Westphalia, the transactions of the United States, whose independence it had legalized, were so intermingled with those of the other European powers, that they form part of the general history of Europe. In continuing this narrative, many of the events which regarded the country here treated of, though important in themselves, must be slightly passed over, because they are to be found under the heads of ENGLAND, EUROPE, FRANCE, and GERMANY.

The conclusion of hostilities had found the nation in a condition of great poverty as related to the governments of the several states, but of great wealth as regarded numerous individuals. The states were deeply in debt, but their creditors were almost exclusively citizens, not to say subjects of the country. This produced what has been called the funding system, which has since been followed by other nations.

Disputes had arisen between the states of Holland on one hand, and the Prince of Orange and the smaller states on the other, respecting the diminution of the army and navy, and the conduct of the officers who had abandoned Brazil. These controversies were carried to such a height that the Prince of Orange would have besieged Amsterdam, towards which he had actually advanced, if he had not been prevented by the opening of the sluices, by which his army would have been drowned. This excited against the prince great unpopularity, when he was carried off by the small-pox, in the twenty-fourth year of his age, leaving no son, but his wife pregnant, who was delivered of a son, afterwards William III. king of England. The civil wars of England were favourable to the trade of the Dutch, though it involved them in war with the government which succeeded the death of Charles I. The several parties in Holland had carefully watched to maintain a neutrality between the monarchical and republican parties in England; but the intemperance of the royalist emigrants, displayed in the murder of Dorislaus, who had been accused of participation in the legal murder of Charles, and of some other rash proceedings, gave the republicans a pretext for commencing hostilities. This led to a naval battle in 1652, when Blake gained some advantage over Van Tromp, though his fleet was much inferior, at least in number of ships, if not in weight of metal. The Dutch instantly fitted out a still larger fleet under the command of De Ruyter, which was met by the English channel fleet under Sir George Ascough. They fought during three successive days, but parted, each claiming a victory. De Witt was then appointed commander in chief of the Dutch fleet, with De Ruyter as his second. Blake, who had sailed to the north after his former battle, collected his ships, and was reinforced by Admirals Penn and Bourn with their squadrons. The two fleets engaged on the 30th of October. The battle was most resolutely contested, but night terminated it before it was decided, and the next day the Dutch entered Goree, declining farther conflict. The fleet of Holland was quickly repaired and reinforced, and placed once more under the command of Van Tromp. Blake had not been furnished in as prompt a manner with reinforcements as his antagonist, and was thus inferior. A tremendous encounter took place on the 25th of November, in which the Dutch were victorious. In this action Blake's flag-ship was disabled, two others were taken, two burned, and one sunk, whilst Van Tromp lost but one of his ships, which was blown up by accident. The engagement lasted from eleven in the morning till six in the evening, when darkness favoured the escape of the shattered remains of the English armament.

In the early part of 1653, both the republics addressed their chief attention to the preparation of their fleets. Blake was enabled to muster sixty sail, with which he attempted to intercept a large convoy of merchant ships, protected by Van Tromp's more numerous, if not more weighty force. On the 18th of February the two contending fleets met, when there ensued an obstinate and bloody conflict, which lasted three days, at the end of which Van Tromp retreated with the loss of eleven ships. The English had lost but one, but the whole fleet was so shattered that they could not pursue. The loss in killed and wounded was nearly equal on both sides; and though the English gained the victory, Van Tromp, by his excellent seamanship, was enabled to convey in safety to the Dutch ports the numerous trading vessels which he had been sent to protect.

At this period Sweden discovered a disposition to join her fleets to those of England, but the diplomatic skill of the Dutch ambassador prevailed on her to agree to a neutrality; and the king of Denmark made a treaty, stipulating to furnish to the Dutch a fleet of twenty sail, to confiscate the English ships in the port of Copenhagen, and to exclude all English vessels from trading in the Baltic. The Danish ships never joined, but the treaty enabled the Dutch to obtain supplies of timber and other stores. Though secret negotiations for peace had been entertained between Cromwell, now master of England, and De Witt, recently appointed pensionary of Holland, yet, as they terminated in nothing, the most extraordinary preparations were made to continue the conflict. In the beginning of June, Van Tromp, seconded by De Witt and De Ruyter, appeared on the ocean with a fleet of ninety-eight men of war and seven fire-ships. They were speedily met by an English fleet of ninety-five sail and five fire-ships, commanded by Blake, Monk, and Dean. On the 2d of June an obstinate battle took place, which speedily terminated in favour of the English. The victory was complete. Three of the best Dutch ships were sunk, two blown up, eleven captured, with many merchantmen; and the whole of them would have been destroyed, but for their timely retreat to the shoals, where the larger English ships could not follow them. The English did not lose a single ship, but Admiral Dean, one captain, and some few inferior officers and seamen, were killed. Van Tromp attributed his defeat to the inferiority of his ships in size and in weight of metal, and to the want of sufficient ammunition, especially gunpowder.

In consequence of this disaster, the party opposed to the house of Orange raised a cry in favour of peace, and some secret negotiations were carried on with Cromwell; but the public voice was strongly in favour of the Orange party, and compelled the government to renew the naval war. Another fleet superior in numbers was hastily prepared, and ready to proceed to sea in the middle of July. This last fleet amounted to one hundred and twenty sail, and they proceeded as soon as collected to engage the fleet of England, commanded by Monk, Lawson, and Penn, between Scheveningen and the mouth of the Meuse. But Tromp fell early in the action, and his death had a bad effect. A rout followed, and the Dutch lost twenty-six ships, with 4000 men killed, and near 2000 prisoners. The English lost some ships, had 600 men killed and 1000 wounded; but their ships had been so severely shattered that they were immediately obliged to seek repairs in their own ports.

The Dutch, though defeated, were not dispirited, and prepared to renew the contest, unless Cromwell would abandon his proposition for the annihilation of the power of the Orange family. He however had determined on a war with Spain, and on expeditions to Spanish America. He withdrew his propositions respecting the house of Orange, but obtained others excluding the royal family of England and their adherents from all refuge within the states, and thus a peace was concluded. The states of Holland bound themselves to exclude the house of Orange from the stadtholderate, but the other states did not agree to it; some of the members even of that province protested against the exclusion, and it was highly unpopular with the great body of the citizens everywhere but in Amsterdam.

The war with England, though short in its duration, had been very expensive as well as sanguinary. It was however no sooner at an end than the Dutch were engaged in hostilities with the Portuguese respecting their settlements in Brazil, which were terminated without any decisive naval combat. But many of the ships of Portugal were captured; and De Ruyter was sent with a fleet to make demonstrations before Lisbon, but having encountered severe storms, his ships were so much damaged that he was compelled to return to repair them, and soon afterwards peace was concluded.

The Dutch next interfered in a contest between the Danes and the Swedes. The latter power had besieged Copenhagen, when the Dutch admiral Opdam was despatched to the Baltic for its relief. He attacked and defeated the Swedish fleet under the walls of Cronenburg, and, by the supplies given to the Danes, saved their capital. A peace was soon afterwards concluded between the northern powers, through the mediation of Holland and England.

The death of Cromwell, in September 1658, had a favourable effect on the Orange party in the United Provinces, whilst the restoration of Charles to the throne of England strengthened it still more; and, though Holland opposed it, a settlement of a large sum was voted to support the household, and carry on the education of the prince. This became necessary from the French king having, upon some very frivolous pretences, seized on the principality of Orange. Charles and his adherents were full of animosity towards the Dutch; and they, elated with their independence, and their powerful naval forces, were not disposed to yield to the indignant superiority which the restored monarch had assumed. The Louvestein faction had again, under De Witt, reared its head in Holland, and some efforts were made to form a union with France, with the view of making a conquest of the ten Netherland provinces, and dividing them between France and Holland. By this proceeding, suspicions and jealousies were created towards the states, on the part of all the other governments of Europe. Towards England the Dutch had shown some animosity, and held language the more presumptuous because their party in England, the remains of the Cromwell faction, had assured them that, from the want of money, Charles would be unable to go to war. To the dismay of the Louvestein party in Holland, the king resolved on hostilities; and in April 1665, his parliament having voted abundant supplies, a fleet under the command of the Duke of York issued forth, and, after the capture of some merchant ships, finding no enemy, returned to Harwich. The states of Holland and Zealand with great activity prepared a naval force of 120 sail of vessels. The commander, Opdam, was met on the 1st of June by the Duke of York with 100 sail, and, after some manœuvring during two days, a battle was fought, in which the English were victorious, chiefly, as the Louvestein party affirmed, from the treachery of some of the captains of the Dutch ships. Their admiral was blown up in his flag-ship; the second in command, Cartemaer, was wounded, and died a prisoner; and eighteen ships, with 6000 men, were captured. The loss of the English was but one ship, and that of men on board the duke's ship was 200: the rest of the fleet had suffered very slightly; but Admiral Lawson, one of the most brave and skilful of the English commanders, fell in the conflict.

The remains of the Dutch fleet made a skilful retreat, and great vigour was exerted to reinforce it. The plague at that time raged in London, and prevented equal exertions from being made, so that the Dutch were enabled early in the following year to assemble a force of eighty-three large ships, furnished with much heavier metal than they had before employed. This force was greater than any that the English could oppose to it. A part too of the English fleet had been despatched to cruise in the mouth of the Channel, by which the grand fleet under the Duke of Albemarle was rendered still more inferior to that of the enemy. The Dutch were commanded by De Ruyter, and the opposing fleets met, and engaged on the 1st of June. The contest continued with great vigour throughout the day; but a reinforcement of sixteen ships having joined De Ruyter, Albemarle drew off, but being pursued, he turned on the enemy, and renewed the battle. During this fight the English Channel fleet made its appearance under Prince Rupert. The contest continued, on the whole, four days. The English then retreated in good order, with the loss of twenty-two ships. The Dutch had lost only seven ships, and were enabled to keep the sea, thus claiming the victory, and even threatening a descent on England.

The English fleet was so quickly reinforced, that on the 24th of July it again appeared at sea, and once more encountered the enemy with success. Three of the Dutch admirals and twelve captains were killed, with 2000 men; and seven ships were sunk, but none taken. After this last battle the English had the command of the sea, and inflicted a severe retaliation for the losses and mortifications they had endured. This produced great exhibitions of party-spirit in Holland, and also disposed them to peace. England, by the extravagance of its sovereign, by the sufferings of the plague and of the fire of London, and the intrigues of France, was much in need of peace.

Conferences were accordingly opened at Breda; but King Charles, with the negligence which characterised his government, had not stipulated for a cessation of hostilities during the negotiations. De Witt took advantage of this, and despatched a fleet to the Thames, which advanced to the Medway, and thus closed for a short time the port of London, at the same time threatening the naval arsenal of Chatham. This in its issue was little more than a bravado, though, after retreating from the Thames, the Dutch made some valuable captures. The negotiations at Breda were however carried on, and peace finally concluded on the 10th of July 1667.

This treaty was followed by one between England, Sweden, and Holland, designed to oppose the growing power of France. The king of England, at that time a pensioner, as well as some of his ministers, on the court of France, behaved with the greatest duplicity, and, upon the most frivolous pretences, resolved to aid France in her projects to conquer the whole of the Netherlands. Under pretence of supporting the triple alliance, Charles obtained money from his parliament, and then determined to attack the Dutch commercial fleets, which were navigating the ocean in full security in the state of peace which had been established. A rich fleet from the Mediterranean was expected to arrive in 1672, when Admiral Holmes was sent with a naval squadron to intercept it. Holmes assumed a pacific behaviour, but the Dutch distrusted him. He made an attack on the fleet, and took one of the ships of war and three small merchant vessels; but the rest, fighting as they retreated, reached the ports of Holland in safety. This naturally produced a declaration of war; and France, joined with England, was engaged in a contest, the object of which was to conquer the whole of the Low Countries, and subject them to the dominion of France.

The violent party-spirit in Holland was ground of alarm. The jealousy of the house of Orange had induced the party of De Witt to neglect the land forces, and the army was in a state of indiscipline, and especially in want of skilful officers, as nearly all the more experienced men of that profession were adherents of the house of Orange, and on that account were not employed. The naval force was in a far better state under the immediate control of the Louvestein faction, though many of its commanders were of the Orange party. De Ruyter was enabled speedily to fit out a fleet of ninety-one ships of war and forty-four fire-ships, and with them sailed to attack the fleet of England and France. This combined force, under the Duke of York and Marshal d'Etrées, was at anchor in Solebay on the coast of Suffolk, where the Dutch hoped by the help of their fire-ships to achieve their destruction. But the united fleets either cut or slipt their cables, and fought the Dutch on the open sea. The fight was tremendous, and was only ended by darkness, when the Dutch withdrew to their own ports. The loss on both sides was nearly equal, but heaviest on the English ships, as their new allies took but little share in the action. It was supposed they had secret orders to spare their own ships, whilst the Dutch and English should weaken each other, a supposition confirmed by subsequent events.

In the mean time the army of France had begun to act on the land side, under Louis XIV., who himself took the field. It was the most numerous and best appointed which Europe had ever seen. It amounted to 120,000 men, including the auxiliary troops of the elector of Cologne and of the bishop of Munster. The Dutch had not more than 25,000 to take the field, and the elector of Brandenburg had engaged to furnish an equal number, on the condition that the Dutch navy should assist him in taking Pomerania from the Swedes. The internal state of Holland was disturbed by party-spirit, but neither party were disposed to submit to a foreign dominion. The partisans of De Witt had projected a flight by sea, and made some preparations for the transport of 50,000 families to Batavia. The young Prince of Orange, though of a sickly frame, resolutely encouraged a spirit of defence, hopeless as it appeared; and when asked what he should do if the French should conquer the country, gallantly replied, "die in the last ditch." This inspirited others, and by the universal voice he was declared stadtholder with unlimited power, and the De Witts were prosecuted, stripped of their wealth, sentenced to perpetual banishment, and murdered by the populace.

In the mean time the French had made a rapid progress, and, proceeding by the Rhine, had subdued the provinces of Utrecht, Guelderland, and Overyssel. Amsterdam, Rotterdam, the Hague, with Middleburg, and the islands, were reduced to great straits, but were held by the Prince of Orange. As a last resource, the patriotic resolution was taken to drown the country, with its invaders. By this step, when the sluices were opened, the French were in part drowned, and such diseases broke out in their army that Amsterdam was saved. Louis had made more than 24,000 prisoners. These he could no longer keep, and on their release they joined their countrymen. The spirit shown by the Dutch had excited an interest in their favour with the emperor of Germany and other princes of the empire, and even the Spanish governor of the Netherlands sent to their aid a force of 10,000 men. A diversion too was operated in behalf of the Dutch by the elector of Brandenburg, and, though impeded by the French general Turenne, it proved of some benefit to the states.

Charles, though somewhat dissatisfied with the French, sent an English fleet to act in combination with that of France, and conquered the province of Zealand; but contrary winds rendered the attempt unsuccessful. In the beginning of 1673, an attempt was made by a French division under the Duke of Luxembourg, to march over the ice and seize Amsterdam and the Hague; but this attempt failed with great loss to the invaders, owing chiefly to a sudden thaw. In the same year a combined English and French fleet, the former commanded by Prince Rupert, and the latter by D'Etrées, engaged the Dutch fleet under De Ruyter and Van Tromp. After much cannonading, in which the French were accused of backwardness, the conflicting navies returned to their ports, each of them claiming a victory. This occurred on the 14th of June.

By this time Spain had declared war against France, the Imperialists had advanced, the invading army was compelled to abandon its conquests in Holland as rapidly as it had gained them, and the dominions of the elector of Cologne, the ally of France, including the city of that name, and Bonn, were occupied by the allies and the armies of Holland.

These events led to negotiations under the mediation of Sweden, and in 1674 a peace was concluded between all the belligerent powers. The transactions of the negotiators were so managed by the address of the Prince of Orange, as to enable him to lay the foundation of the grand alliance, by which, in subsequent periods, after his accession to the English throne, the power of Louis XIV. was reduced to the lowest point.

In 1677 the Prince of Orange was married to the Princess Mary, daughter of the Duke of York, and niece to Charles; an event hailed as favourable to their interests by the Dutch, and by those in England who were unfavourable to the mean dependence on the French court, to which Charles' pecuniary wants had subjected him.

The Dutch sent a fleet under De Ruyter to join that of Spain in the Mediterranean. In a contest with the French De Ruyter was mortally wounded, though his fleet was victorious; but in a subsequent battle the Dutch and Spaniards were defeated with great loss, by which the French became masters of the Mediterranean.

The Prince of Orange had attained to supreme, almost to absolute power in Holland. His ruling principle was hostility to France, arising from the manifest ambition of Louis XIV. With this impression he was induced to direct all his efforts to counteract the influence of France, especially amongst the German states. As his father-in-law James, who had ascended the English throne, was acting in an opposite direction, to the great disgust of the leading Protestants of his dominions, the prince opposed him by maintaining a correspondence with the discontented. They were received by him with some degree of privacy; but as James proceeded in his measures against the established religion, they became too numerous to escape the notice of France, though they engaged but little share of the attention of James, probably from the deceit of one of his ministers, who has been accused by history of having acted a false part towards him. A jealousy existed, though with no great force on the part of James, towards France, and this induced him to decline the acceptance of offers of succour from Louis XIV.

The Prince of Orange, under the pretext of a dispute with Bavaria and the elector of Cologne, collected an army of 14,000, with transports sufficient to convey them to England. After being once driven back by storms, the forces landed in Torbay on the 4th of November 1688; and thus was effected that change of succession usually called the Revolution, the details and consequences of which belong more to the history of England than to that of Holland.

The change of sovereigns brought England into the grand alliance against France; and the united navies, in 1692, fought the battle of La Hogue, in which, after a contest of three days' continuance, the French admiral Tourville was completely beaten, and suffered the loss of sixteen of his largest ships. The Dutch commerce suffered considerably by the privateers of France, especially by the operations of the celebrated Du Bart; but these and other hostilities were suspended by the peace of Ryswick, concluded in 1697.

The death of King William occurred in 1701, just at the commencement of that war respecting the Spanish succession, which continued till the peace of Utrecht, in the year 1712. The transactions connected with it belong more to the history of other countries than to that of Holland, though the Dutch states under the succession of William, who was created stadtholder, continued to bear a considerable share in the contests.

About the year 1742 the Louvestein party had gained the upper hand in Holland; and Cardinal Fleury, the French minister, engaged the states in some intrigues, and even hostilities, upon which a stadtholder was again appointed, and soon afterwards a general peace was concluded, that of Aix-la-Chapelle, in 1748.

The prince stadtholder died in 1751. He had seen but little service in the field, yet he had proved himself an active and skilful chief of the republic. He left a son and daughter, both minors; and his office was intrusted, as well as the education of his children, to their mother, a daughter of George II.

Whilst the Seven Years' War raged, from 1758 to 1763, Holland maintained its neutrality, or at least affected to do so. Great complaints and many discussions arose with England, on a question of neutral rights, which has continued till the present time; but they led to no events of any importance. When the war between England and her American colonies broke out, the question of neutral rights was again resumed; but, in the midst of the discussions on that subject, it was discovered that an attempt at a treaty with those called by us our rebel subjects had been favourably received in Amsterdam, and Mr Laurens, an American ambassador on his passage, was captured with the correspondence. This led to hostilities, in which St Eustatia in the West Indies was taken by the English. In the year 1782 a Dutch fleet was equipped, and met on the Dogger Bank by an English fleet of nearly equal force under Admiral Parker. A bloody fight ensued, which terminated in favour of the English. The peace which followed, in 1783, restored tranquillity to Holland, which had suffered severe losses by captures during the short hostilities that had been carried on. After the peace, the Anti-Orange party in Holland, which, from the hereditary dignity having been conferred on that family, had appeared extinct, gained fresh influence, and again raised its head. The Princess of Orange, the sister of the king of Prussia, had been grossly insulted, upon which that monarch demanded satisfaction; and this being refused, he marched an army into Holland, which was feebly defended by the clamorous boasters of their bravery. Amsterdam was occupied by the Prussians in September 1787; the stadtholder was reinstated in the power of which he had been deprived; and a strict alliance was formed with England and Prussia. Though tranquillity was thus restored, the party which had been suppressed were dissatisfied, and watched for the fittest opportunity to avenge their mortifications.

Nor was it long before an occasion presented itself. In 1794, when the French republican flag was displayed on the frontiers, the defeated party were active and clamorous, and when the country was invaded by the army of Pichegru, they gave it every assistance in their power. This state of affairs, with a frost of great intensity, which admitted the passage on the ice of the artillery and heavy baggage of the French army, rendered the conquest of Holland of easy accomplishment. In 1795 the Orange family fled and took refuge in England, whilst a republican constitution, framed by the French faction of the day, was established, with a directory of five persons as the executive power. The new republic, called the Batavian, was compelled to cede to France some parts of its territory, with the cities of Maestricht and Venlo, and the province of Limburg. An immediate demand was enforced for the payment of ten millions sterling, and the army of France was to be paid, fed, and clothed at the expense of the Batavian republic. Under this state of things, one part of their navy was given up to the British by the dissatisfied seamen, another part fought and were defeated; their colonies surrendered or were taken by the same power, their commerce was confined to mere coasting, and the bank of Amsterdam nearly shattered; but not a fraction of the pecuniary demands was abated by their new allies.

The constitution was new-modelled in 1801. The number of the directors was diminished, a kind of upper house was created in imitation of the council of ancients in France, and the country was divided into eight departments. The peace of Amiens gave back to Holland their colonies in South America and the Cape of Good Hope, but left Ceylon in the hands of England. When the war was renewed, the restored colonies were again captured, their ports were strictly blockaded, and every hope of prosperity was extinguished. In April 1805 a new constitution was introduced by France, and Schimmelpenninck was made sole director; but his integrity was unable to serve his country in the difficult circumstances in which both he and it were placed. It was therefore determined by Bonaparte to create Holland into a separate kingdom, and place his brother Louis on the throne. This was executed in June 1806. On his accession Louis availed himself of the talents and integrity of the late director, and acted, as far as he was able, for the benefit of the people over whom he had been placed as sovereign. But none of his efforts proved effectual in removing the general distress, and even in the few which were made, he was so controlled by his imperial brother, that, without communicating his intention, Louis withdrew himself from Holland, renounced all authority, and, with but scanty means of subsistence, took up his residence as a private individual in the dominions of the emperor of Austria. This step has been represented as having been hastened by his incapacity to relieve the distress which had been produced in his dominions by the landing of the English in Middleburg in their attempt upon Antwerp in 1809.

Louis retired in July 1810, and Holland was by a decree of the emperor incorporated as an integral part of his empire; Amsterdam was declared to be the third city of the imperial dominions; the French conscription law was extended to the whole of Holland, and those taken under it were equally divided between the land and the sea service; and the country was then, for military purposes, formed into two divisions.

Under this military yoke the Dutch suffered till after the battle of Leipsic in October 1813, when a part of the victorious army under General Bulow advanced toward Holland, and met there an English division under General Graham. On the 20th of November the two commanders called on the Dutch to join the cause of the allies. Two days before this, Count Hogendorp, a moderate Orangist, had privately collected in his house a number of the most distinguished persons, who, like himself, had formed part of the ministry from 1788 to 1795, and persuaded them to take upon themselves the provisional government, till the Prince of Orange, who was expected from England, should arrive.

A correspondence was opened with General Bulow, and with the allied monarchs, who had advanced to Frankfort; and invitations were addressed to the prince, who with little delay arrived at the Hague, and proceeded to Amsterdam amidst the rapturous acclamations of the assembled crowds. Proclamations had been circulated generally, headed, "The Netherlands are free, and William I. is the sovereign prince of this land of liberty." He however refused to assume any power till an assembly could be convened, which might properly be considered as a fair representation of the whole people. An assembly of notables, consisting of the most distinguished men of all parties and professions, was speedily called together. The number summoned was 600; of these, 125 declined attending, some on account of their age, others from ill health or personal reasons. With the dissent of only twenty-six voices, the prince was declared king, and a constitution decreed, which secured to him considerable power, limited, however, by two legislative assemblies.

When the French forces were compelled to abandon the ten ancient provinces of the house of Austria, these were considered as conquests made by the allied powers, who assumed the disposal of them. The congress of Vienna, of which Austria, the former sovereign of those provinces, was a member, resolved that they should be united with the seven provinces, and form together one independent kingdom, under a constitution, of which the princes of the house of Orange were to be hereditary monarchs. As an indemnification to the prince, now king, for the loss of his states in Germany, the duchy of Luxembourg, with the exception of the fortress, was given up to be added to this newly-constructed kingdom, and in it was included the ancient bishopric of Liège.

Before the complicated arrangements which the union of these parts required could be completed, the return of Bonaparte from Elba, and the revolt of the French army, created impediments to the settlement of internal affairs. But this newly-constructed kingdom, which was the first object of attack, entered with energy into the contest, and their troops, mustered as they had hastily been, took an honourable part, under the eldest son of the king, afterwards William II., father of William III., the present sovereign, in the grand events of that short but brilliant campaign of 1815, which ended in the decisive victory of Waterloo.

The consolidation of such heterogeneous bodies as the inhabitants of Belgium and those of Holland was a difficult task, owing to their differences of religion, of laws, of language, and of occupations. The Belgians were rigid Catholics, and their clergy strove to prevent the toleration of all other professions; their laws had all been founded on the system of the ancient Dukes of Burgundy, but altered to suit the Code Napoleon. The language spoken by the major part of the people, though it nearly resembled the Dutch, had considerably varied from it in the practice of two hundred years; and besides, a numerous portion of them spoke French almost exclusively, whilst another portion spoke the Walloon, and in Luxembourg the German language predominated. The Dutch were principally conversant in trade, in the fisheries, and in manufactures, whilst the Belgians were chiefly employed in agriculture.

The members of the legislative body contained nearly an equal division of the two countries; and as they acted rather with the feeling of delegates from the parts by which they were chosen, than as the representatives of the interests of the whole community, their decisions were subject to great fluctuations, according to the number of Dutch or of Belgian members who might happen, by sickness or by accident, to be prevented from being present when the votes on a particular proposition were taken. This inconvenience might have been removed by time, if other causes had not been in operation. The agriculturists wished to monopolise the whole supply of corn by means of a restrictive law; but the distillers, who used a great quantity of Baltic corn in making gin, and the speculative merchants in grain, who were a medium for supplying that commodity to a great extent from countries in which it was cheap, to countries in which it was dear, claimed a continuance of the free trade which they had long enjoyed. Though this point was finally settled in favour of the Dutch party, it caused a rankling feeling in the minds of the Belgians. The assemblies, besides their ordinary occupations, had their attention constantly directed to the composition of a system of law, applicable both to civil and to criminal cases, and had made great progress in the work. After much opposition to religious toleration, in which the king displayed both temper and firmness, a concordat was made with the pope, which, if not quite satisfactory, would, if left to itself, have probably removed all existing obstacles. The difference of language, though represented by those who availed themselves of every pretext to produce mischief, as of importance, was not in reality of very great moment. The Belgic and the Dutch are scarcely more dissimilar than the English and the Scotch, and one or the other was the language of a vast majority. All the books of any value were in the Dutch dialect, but they were neglected by the Belgians, of whom the few that could and did read drew their ideas from French publications. By directing all law proceedings to be carried on in the vernacular languages, a body of impetuous young men, imbued with French principles, were inflamed against the government, and gained more influence than they could have obtained if the exclusion of the French tongue from the courts had been gradually and not suddenly attempted.

In spite of these obstacles to a more perfect union, no country ever made so rapid a progress in prosperity as was exhibited in Belgium. The products of its soil, the iron and the coals of Liège and of Luxembourg, found most beneficial markets in Holland. The corn was, in spite of that imported from the north of Europe, sold at profitable rates. The trade with the Dutch colonies being opened to them, and the valuable port of Antwerp being no longer closed, Belgium made a great progress in foreign trade. The effect of this was to create new manufacturing establishments of cotton, woollen, and linen goods, and to extend those which had before existed. The advancement of the country was manifested to the most casual observer, and seen in the increase of private and public buildings, and in the improvement and embellishment of the old ones, in every city, town, and village.

The state of ease and improvement so striking in Belgium was, however, no security against the union of opposite factions, who agreed in nothing but in the work of inflaming the worst passions of the most ignorant part of the community, who, though highly bigoted to their religion, were made tools to overturn the government, by those who avowedly hated it.

The Parisian revolution of July 1830 quickly produced a similar one in Brussels. The events passed as rapidly as in the former city. There were few or no troops, a negligent and inefficient police force, and no spirit amongst those who possessed property, to protect it against the plunderers. They prayed the king to send troops to protect them; but when these arrived, the inflamed Belgians, who were from policy mixed up in the same ranks with the Dutch, would not act, and they abandoned the city. The mob, thus triumphant, compelled the feebler but richer citizens to submit to their demagogue leaders. This produced a declaration of independence against the house of Orange.

In the mean time, the Dutch, who were not without causes of complaint of the greater favour shown to the Belgians than to themselves, were firm in their allegiance to the monarch, and wished for a separation of the two countries. This measure was proposed and discussed in the legislative assembly at the Hague, and ultimately, by a majority, but not a large one, determined upon.

Application was made by the king of the Netherlands, to the several powers who had at Vienna sanctioned the union, and guaranteed to him the possession of his throne. This led to discussions and negotiations, during which a monarch was elected by the Belgians. They wished one from the family of Napoleon, or that of Orleans, but were not allowed a free choice, and at length Prince Leopold of Saxe-Coburg was placed on the throne.

The Dutch soon composed an army, which, though inferior in number to that of Belgium, invaded the country. The Belgians displayed neither courage nor discipline, but fled in all directions; and their new king would, but for an accident, have been made prisoner. A division of the French army advanced to the aid of the Belgians, upon which the Dutch retired.

The citadel which commanded the city of Antwerp was still garrisoned by a Dutch force. It appeared proper to England and France that this should be given up to Leopold; and as the Dutch refused to surrender it till all other subjects of contest between the two countries were arranged, it was resolved to compel its surrender by warlike measures. The ports of Holland were blockaded, and the fortress of Antwerp was attacked by a French army, and, after a gallant defence, compelled to capitulate. The embargo was then taken off, and all hostilities ceased in 1833. (W. J.)

The article Belgium contains a full statement of the political events connected with the separation of Belgium from Holland. The more recent history of Holland is one of progress and general prosperity without presenting any very striking events. In 1844, as a natural consequence of the Belgian Revolution, the public accounts of Holland showed a large deficit which the nation met with characteristic energy, by voluntarily subscribing a loan of ten millions sterling. In 1848, the Revolution in France was followed in Holland by a judicious revisal of the fundamental law, and extensive measures of reform, the results of which will be given under the section *Government*.

The partitioning of England into Roman Catholic bishoprics, was followed in 1853 by a similar interference of the Pope with the Netherlands' territory, the effect of which will be stated under the section *Church*. The adoption by Great Britain of the principles of free trade was highly acceptable to the Dutch merchants, and was followed by the government of Holland in 1854, abolishing the import duties on a great number of articles of merchandise. During the recent war with Russia, the Netherlands' government maintained a complete neutrality. The army and navy were kept on the peace establishment, and the trade and commerce of the country do not appear to have been greatly disturbed.

There have been several recent changes in the royal family. William I. abdicated the throne in favour of his eldest son, the Prince of Orange, in 1840, and died in 1843.

William II. dying in 1849, was succeeded by the present sovereign, William III., born 19th February 1817. He was married on the 18th June 1839, to the Princess Sophia Frederiker Mathilda or Würtemberg. They have two sons, William Nicolas, Prince of Orange, born 4th September 1840, and William Alexander, born 25th August 1851.

Physical geography. The kingdom of the Netherlands comprises the territory of the ancient republic of the Seven United Provinces, with some portions of Limburg. It does not include that portion of Luxemburg which the king of the Netherlands possesses, with the title of Grand Duke, as a part of the German confederation. It is situated between N. Lat. 50. 44. and 53. 34., and E. Long. 3. 30. and 7. 10. It is bounded on the E. by Germany, from which it is not separated by any natural barriers, on the N. and W. by the German Ocean or North Sea, and on the S. by Belgium.

The greater part of this country has been formed of mud deposited by rivers in the same manner as the Egyptian Delta is formed by the Nile. By tracing the courses of these rivers we obtain an idea of its conformation. The Rhine enters Holland at Lobith, a little below Emmerich, where it is 2300 feet broad; and then divides into two branches, the southern receiving the name of the Waal. At Westervoort, the northern branch is again divided, and there its right arm is called the New Yssel. Then the left branch, taking a westerly direction, is again separated at Wyk into two, and the left branch is called the Lek. The right branch flows on to Utrecht, and being there divided for the fourth time, receives for its right arm the name of Vecht; while the left, which still retains the name of Old Rhine, taking a westerly direction by Waerden and Leyden, finally makes its way at Kalwyk to the North Sea.

The Meuse enters the Netherlands' territory above Eysden in Limburg, and flowing northwards, unites with the Waal, near Loevestein; then divides near Dort, forming the island Ysselmonde. The right branch at Krimper is joined by the Lek, then flowing westward by Rotterdam, divides near Flardingen into two branches, and so forms the island Rosenburg. These branches uniting near Brielle, reach the sea at Oostvourn.

The Scheld touches the kingdom of the Netherlands at Fort-Bath, where it divides, forming the islands of S. and N. Beveland, and Walcheren. The left branch reaches the sea at Vlissingen. The right branch flows northward between Zeeland and N. Brabant, dividing near Bergen-op-Zoom, it forms the island Tholen, and the left arm reaches the sea N. of Walcheren. The right branch still separating N. Brabant from Zeeland, divides into numerous channels, by which its waters, mingled with those of the left branch of the Meuse, form numerous islands, and finally reach the sea.

To establish a firm footing amidst so many rivers, the inhabitants have kept them as far as possible within prescribed channels by embankments, and have formed innumerable canals to receive the superfluous waters, and to serve as means of internal communication. The country is thus a net-work of rivers and canals from the one end to the other. The system of drainage, of what would otherwise have been an immense mud-bank, well deserves to be ranked among the wonders of the world. The land thus rescued from the rivers, is nowhere much elevated above the sea, and in many places is even below the sea-level, so as to require still more wonderful defences against the ocean. These defences are in part supplied by the operation of nature, casting up sand-hills along great part of the coast; but where these have not been formed, their place is supplied by dykes of vast extent, built in the course of ages, partly of huge blocks of granite brought from Norway, and partly of bundles formed of young trees, reared expressly for the purpose. These dykes stretch for hundreds of miles along the coast, and with those which line the rivers and canals, and with the requisite sluices, drawbridges, and hydraulic works of every kind, are estimated to have cost not less than L.300,000,000 sterling. They form in so small a country a most astonishing monument of human industry. Yet they are not greater than the situation requires. They are barely sufficient to preserve the country from the dominion of the waters. The motto on the arms of one of the provinces, "Luctor-et-Emergo," still describes the struggles of the invincible Hollanders requisite for maintaining the ground they stand upon. A destructive inundation occurred so lately as March 1855. The rivers, augmented by the snows of winter, burst through the dykes in several provinces. A fourth part of Gelderland was submerged. The whole province of S. Holland was in the most imminent danger. The embankment of the Rhine having burst in five places in Gelderland, admitted the flood, where it had not extended during 150 years. In Utrecht and N. Brabant, the people of many communes had to abandon their property to the waters, and sought refuge for themselves on the roofs of houses and on trees. The neighbourhood of Zutphen was very speedily converted into a vast lake, and the villagers hastily betaking themselves to boats and rafts, reached with the greatest difficulty the ramparts of the city. This flood which happily subsided after some days, exhibited, while it continued, the promptitude and energy with which the Hollanders have always contended against the peculiar difficulties of their situation. The king immediately repaired in person to the scene of danger, and took his station in the centre of the inundated country, directing all the operations, and giving every possible assistance. A collection ordered by the king for the sufferers produced L.41,667, and private collections reached an equal amount. This sum was immediately distributed among the distressed families, whose habitations and lands had been laid waste. To drain off the remainder of the flood, to rebuild the dykes, to repair the Rhine railway, a considerable part of which had disappeared, could not be so quickly done, but all this the patriotism of the Hollanders has completely accomplished.

This recent calamity illustrates the origin of the lakes, which, although greatly diminished since the sixteenth century, are still numerous and extensive.

The Biesbosch, in the neighbourhood of Dort, was formed in 1491, burying 72 villages under water, and drowning 100,000 persons. Of these villages 34 have been rebuilt, as the progress of drainage permitted. The Dutch method of draining is highly ingenious. A marsh or lake is inclosed with a dyke to prevent any water from flowing into it. Windmills are then erected on the edge of the dyke, each of which works an Archimedean screw, and the water thus raised is discharged into a canal which conveys it to the sea. The lake of Haarlem was the most celebrated of those occasioned by the overflowing of rivers; and its drainage by the application of steam, is a great improvement on the old method of draining by windmills. (See HAARLEM.)

Besides these inundations from the rivers, Holland has experienced many others from the sea, which have left large tracts of country submerged, of which the Dollart and the Zuider-Zee are the most extensive.

The Dollart between Groningen and East Friesland originated in 1277, and was greatly extended in the three following years. One town, thirty-five villages, and several hamlets were overwhelmed. It has from time to time been much reduced by drainage. The Zuider-Zee was formerly only a lake, known by the name of Flevo, communicating by two channels with the North Sea. Subsequently the sea covered the lowlands, and the channels of communication were multiplied. Now the expanse of water is 80 miles long, and from 20 to 40 miles broad. Proposals for its drainage have been made to the government, and are under serious consideration. As means of communication between Amsterdam and the North Sea, the Zuider-Zee has long been unsatisfactory, on account of the Pampus bank and numerous shallows. Sometimes, in consequence of long-continued northerly and easterly winds, its bed is almost dry, and vessels are everywhere lying on the sands. A substitute has accordingly been provided for it in the great North Holland Canal, one of the most stupendous works of the kind in existence. It was begun in 1819, and finished in 1825, at a cost of about one million sterling. It is about 50 English miles in length. Its breadth, at the surface, is 124½ English feet, at the bottom 36. The depth is 20 feet 9 inches. Its level is that of the high tides of the sea, from which it receives its supply of water.

While the country possesses abundant means of communication by rivers and canals, it also has excellent roads. The highways in the central provinces are among the best in Europe. They run for miles in a straight line along the summits of the dykes, and are thus at once dry and elevated, commanding extensive views. Between the large cities they are broad, and usually paved with a kind of small hard bricks, called *klinkers*, made of sand mixed with the clayey mud obtained in cleaning the canals. They are fitted so exactly to each other when laid down, that scarcely a crevice is to be seen; and being well covered with sea-sand, they sustain little injury from carriages. Railways have also been made, or are in progress in all directions. Those between Rotterdam and Amsterdam, and between the latter city and Arnheim have been in operation for several years. Rotterdam is also in communication by railway with Utrecht *via* Gouda, and with Antwerp. There is a branch between Antwerp and Breda. Maestricht, in Limburg, is also in communication with Aix-la-Chapelle.

The general aspect of this country is different from that of any other in Europe. The roads and canals are usually lined with willows and other trees, which afford an agreeable shade and relieve the uniformity of the landscape. Innumerable villas are seen decorated with the utmost nicety of art. Spires, church towers, villages admirable for neatness and cleanliness, large and well-built cities, rapidly succeeding one another, meadows in vernal green, varied by sheets of water, cattle in large herds, barges towed by horses, or spreading a sail to catch a favouring breeze—every thing and every place in the highest order and perfection; such are the sights which Holland supplies in abundance, and in respect of which it has no parallel in any other part of the world.

The following Table gives the Statistics of Holland as ascertained by the Census, 31*st December* 1853.

PROVINCES.	Population.	Houses.	Acres of Cultivated Land.	Acres of Roads and Waters.	Acres of Uncultivated Land.	Acres of Total Extent.	Proportion Uncultivated.
North Brabant	405,525	3,106	704,301	97,283	453,876	1,263,136	1 : 2·78
Gelderland	387,423	2,893	784,311	51,982	409,713	1,253,155	1 : 2·309
South Holland	391,493	3,067	606,455	103,802	32,236	750,071	1 : 23·26
North Holland	514,755	2,502	421,411	61,835	126,926	616,354	1 : 4·85
Zeeland	165,075	1,723	353,228	8,026	43,968	409,480	1 : 9·31
Utrecht	155,324	1,103	271,587	21,464	43,338	349,114	1 : 7·82
Friesland	259,508	2,184	632,128	66,871	103,248	807,643	1 : 7·82
Overyssel	227,683	1,532	430,922	20,283	379,459	834,450	1 : 2·08
Groningen	197,101	1,860	444,147	28,922	100,599	578,265	1 : 5·74
Drenthe	89,944	603	212,669	5,219	437,120	656,498	1 : 1·50
Limburg	211,401	1,000	352,259	4,942	182,862	545,006	1 : 2·84
	3,203,232	21,573	5,213,418	470,629	2,313,345	8,053,172	1 : 3·18

The colonies in Asia—Java, Amboyna, Banda, Ternate, Macassar, with settlements in Sumatra and Borneo, also Desima in Japan, are stated to have a population of	16,478,137
The colonies in America—Surinam and the islands of Curacao and St Eustathius,	90,581
The colonies in Africa—Elmina, on the coast of Guinea,	100,000
	16,668,718
Population of Holland	3,203,232
Total subjects of the King of the Netherlands	19,871,950

The population has increased by 60 per cent. in 57 years at the following rates:—

Years.	Populations.		
From 1796 to 1815	166,422,	or annually,	8760
... 1815 ... 1830	380,321	...	25,355
... 1830 ... 1840	236,525	...	23,652
... 1840 ... 1850	187,887	...	18,788
... 1796 ... 1853	1,101,368	...	19,322

The number of the inhabitants of 87 cities in 1853 was 1,163,559, and of the country 2,039,673. The population of the principal cities at the same period was the following:—

Cities.	Pop.	Cities.	Pop.
Amsterdam	247,730	Haarlem	27,770
Rotterdam	90,888	Maestricht	26,919
The Hague	75,276	Leuwarden	24,461
Utrecht	50,710	Nimeguen	22,009
Leyden	37,106	Dort	21,905
Groningen	35,126	Bois-le-Duc	21,862

Climate.

In respect of climate Holland labours under many disadvantages. In winter it is much colder than England, and the waters are frequently frozen for three months. Even the Zuider-Zee is sometimes frozen over. The temperature has been sometimes as low as 23° below zero of Fahr., and sometimes as high as 102. In summer cold nights often succeed to days of intense heat. The climate generally is variable. The atmosphere, especially in the western provinces, is loaded with moisture, and there agues, dropsies, pleurisies, and rheumatisms are frequent. Gelderland is the healthiest province, but all the eastern side of the country is comparatively salubrious. Holland is frequently subject to violent gales of wind, which, when they blow from the W. or N.W., are apt to cause inundations of the sea.

Agriculture.

This remarkable country largely rewards the skill and labour of the agriculturist. The south and central provinces are the most fertile. As has been shown above in one of the tables, there are still extensive tracts of uncultivated land, although much has been reclaimed of late years. The farms in the best parts of Zeeland vary in extent from 166 to 330 acres each. In South Holland the proportion of pasture to arable land is about 2 to 1. In Friesland the quantity of pasture is more than eight times that of arable land. In Gelderland there are large plantations of apple, pear, and cherry trees. Tulips and hyacinths are extensively cultivated in the neighbourhood of Haarlem in fields of several acres each. Pulse and garden vegetables are everywhere raised in great abundance, also woad and madder. Flax is largely cultivated in the south, and especially in the neighbourhood of Dort. Utrecht and Gelderland produce considerable quantities of tobacco. The following are the statistics of the harvest of 1853:—

	Cultivated land in acres.	Produce in quarters.		Cultivated land in acres.	Produce in quarters.
Wheat	177,065	329,267	Peas	25,533	78,780
Rye	448,648	883,036	Beans	32,404	340,133
Barley	108,316	435,866	Potatoes	216,074	2,604,954
Oats	211,218	980,585	Carrots	2,617	...
Buckwheat	157,489	474,055	Flax	51,572	...
Cabbage Seed	53,062	108,154	Tobacco	3,383	...

The rearing of live stock, however, and dairy husbandry, are much more important sources of national wealth than tillage. The lean cattle brought from Denmark and Germany fatten with great rapidity in the Dutch *polders*. Large herds of beautiful cows yield great abundance of the richest milk. Butter and cheese of the best quality are largely exported, and bring great wealth to the peasantry. The Dutch horses are good, and well adapted for draught; the best are those of Friesland. The breeds of sheep, however, are not particularly good.

The statistics of 1853, Dec. 31, give the following numbers for the whole kingdom:—

Horses	236,562	Sheep	826,061
Horned Cattle	1,236,974	Swine	233,900

In North and South Holland, Groningen, and Utrecht, there are made 140,000,000 lbs. of cheese annually, the home consumption of which does not exceed one-twentieth. This large quantity at its average price produces L.1,800,000 sterling annually. The value of the butter is about L.2,000,000 sterling more, of which their own consumption amounts to one-tenth.

Industry.

The soil being almost everywhere alluvial clay and sand, Holland possesses little, if any, mineral wealth. No coal deposits are found; but extensive beds of marine peat of most excellent quality abound, especially in Friesland and Holland, and the manufacture of this into fuel is an important branch of industry. In 1853 the produce of this industry amounted to 31,525,998 tons, on which an excise was paid to the government of L.120,267, after deduction of 10,370,762 tons exempted from excise as being employed in other manufactures. Among the branches of industry, ship-building holds the first place. The ship-building yards are in all 607; and in 1854, 220 new vessels, measuring 54,636 tons, were launched. The Dutch East Indiamen are handsome ships, well rigged, manned, and armed, and are not surpassed either in speed or durability by any similar class of merchantmen in Europe.

In connection with ship-building the saw-mills are worthy of mention. They are in number 397, driven by wind; 81 of these at Zaandam work 324,000 beams yearly, representing an annual value of L.135,000.

The manufacture of bricks and tiles is a great branch of industry, and is indeed most necessary in a country where scarcely any stone is to be found. There are 332 of these manufactories, 70 of which, in Overyssel, employed 1250 persons in 1853; 46 of them at Ryssen produced 16,000,000 of bricks; 7 of them at Zwollerskerspel produced upwards of 8,000,000. In Gelderland this business occupies 4000 persons, and produces 36,000,000 of bricks annually. At Gouda 119 tobacco-pipe manufactories employ 700 persons. Delft still produces the earthenware for which it was long celebrated, but now feels the effect of foreign competition. The white-lead made in Holland is the best in the world, and the use of paint is there most extensive. The oil-mills are 312 in number, and steam power in this branch begins to supersede windmills. There are 112 establishments for the preparation of madder; 65 of these in Zeeland employ 500 labourers. There are 285 manufactories of tobacco. Those at Amsterdam alone employ 766 persons. At each of five other places about 200 are employed. They export largely to North America and Germany. Gin distilleries are numerous and very active. At Schiedam in 1853, 172 of these employed 615 men at from 12s. to 20s. per week. Delfshaven, in that neighbourhood, had 30 more, with 124 labourers. Great quantities of gin are exported in bottles to England, for Australia. It is stated that the only limit to the export is the impossibility of procuring bottles in sufficient numbers. At Amsterdam there are 17 distilleries of liqueurs, which export largely to the west coast of America. The distilleries in all are 324. The breweries 376. There are 27 sugar-refineries. Of three at Amsterdam one employs from 400 to 800 labourers. Here 83,000,000 pounds were refined in 1853, of which 7,000,000 were exported to Great Britain. This branch, however, has of late years been declining.

An important branch of industry is the manufacture of paper. There are 167 paper manufactories, employing more than 3000 workmen, and using 9823 tons of rags per annum. The largest is at Waperveldc, where 69 persons earn L.542 of wages yearly. Forty-two of these manufactories at Appeldoorn exported, in 1853, 20,000 reams of paper to Java; and 21 at Epe produced 43,000 reams. Shoes are made in considerable quantities for exportation at 277 establishments in North Brabant, 128 in Gelderland, 111 in Friesland, and 87 in Groningen. These give full employment at Waalwyk to 475 persons, and at each of six other places to nearly an equal number. The making of wooden shoes is in some places an important occupation. At Epe, in 1853, 51,650 pairs of wooden shoes were made. Amsterdam has a monopoly of diamond-cutting. The diamond-cutters there are 287, employed with 409 other workmen and three steam-engines of 40, 36, and 10 horse-power. 1000 families are supported by this branch of industry. Manufactories of steam machinery and other iron works are on the increase. The largest at Amsterdam employed, in 1853, 1000 hands, paid L.25,605 in wages, and used 2,000,000 lbs. of iron.

The principal woollen manufactories are at Tilburg, and these, 61 in number, employ 3300 persons. They have 26 steam-engines from 1½ to 30 horse-power, and produced in 1853 3306 pieces of goods. Three linen manufactories at Leyden, with 4 steam-engines, employ 400 hands. The Dutch linens are of the best quality. The principal carpet manufactory is at Deventer. It employs about 300 persons.

The manufacture of linen and cotton goods is widely extended over most of the provinces, and in Overyssel alone gives employment to 8865 persons. The number of establishments great and small is given at 528. Silk manufactories have long been established at Haarlem and Amsterdam. One was commenced at Breda in 1848, which in 1851 was in great activity with expectation of further increase. Upon the whole, the Hollanders merit the praise of having attained a high degree of perfection in the mechanical arts, those especially which are in connection with their peculiar situation. Their hydraulical works display not only incredible labour, but wonderful skill and contrivance. They excel all other nations in the construction of mills; they are the best wheelwrights in the world; indeed, in work of every kind they exhibit the highest degree of neatness, strength, and economy.

Fisheries. Julius Cæsar describes the Batavians as deriving a part of their subsistence from the fishery. The herring fishery of Holland was carried on as early as the twelfth century; but what rendered this branch of industry the gold mine of Holland was the discovery by Beukels, towards the middle of the fourteenth century, of the mode of curing and barrelling herring. At a period when the prohibition of eating butchers' meat during two days every week and forty days before Easter was universal, a supply of some sort of subsidiary food was urgently required throughout Christendom; so that the discovery of Beukels was of the greatest consequence, and contributed more, perhaps, than anything else, to increase the maritime power and wealth of Holland. The Emperor Charles V. being at Biervliet in 1550, where Beukels is buried, visited his grave, and ordered a magnificent monument to be erected to record the memory of a man who had rendered so signal a service to his country. For a long period the Hollanders enjoyed nearly a complete monopoly of the herring fishery. They carried it on not only in the bays and inlets of their own country, but along the British coasts, from the Shetland and Orkney Islands to the mouth of the Thames. Their sense of its importance was shown by the saying in common use among them, that "the foundations of Amsterdam were laid on herring bones." In 1610, 3000 vessels, manned by 50,000 fishermen, were employed in this fishery, which then produced L.2,500,000 sterling yearly. In the middle of the eighteenth century 100,000 fishermen were employed. In 1780, owing to the British and other maritime nations giving attention to their own fisheries, the number of Dutch herring vessels was reduced to 200. In 1842 the British vice-consul at Rotterdam reported 165 vessels and 2325 fishermen employed in the herring and cod fishery; the whole number of vessels employed in fishing being 1605, and the fishermen 8350. He stated the produce to be 40,000 tons of salt herrings, 10,000,000 herrings for smoking and drying, and 10,000 tons of salt fish. He estimated the gross value at L.334,000; of which the proportion consumed in Holland was L.30,000; and the value of L.304,000 exported to Germany, Poland, Russia, and Belgium. Since that period the Dutch herring fishery has considerably declined. In 1854 a commission of the states of N. and S. Holland was appointed by royal authority to inquire into its state, and to suggest means for its revival. The whole value of the herrings in 1853 was L.59,916; the quantity being 60,933,800 herrings. The value exported, L.22,999 in salt herrings, and L.14,402 in smoked. The cod fishery at Doggersbank and Iceland, which in 1771 employed 121 vessels, in 1853 employed only 35. The export of fresh fish was valued at L.16,775; and of salt fish at L.5000. But the Hollanders were, if possible, still more indebted to the whale fishery, which they at one time prosecuted to an extent and with a degree of success that distanced all their competitors. This fishery, when in its most flourishing condition, was principally carried on in the seas and bays round Spitzbergen; and there the Hollanders constructed the village of Smeerenberg, where they boiled the blubber, and prepared the oil and the whalebone. The havoc made among the whales, and their dispersion to the coasts of Greenland and Davis' Straits, put an end to the establishment at Smeerenberg, and, with it, to the golden age of the whale fishery. In 1842 there was only one vessel engaged in this once flourishing fishery; in 1853 there were five; and in 1854 there were three. The commissioners give the following statement of the Dutch fisheries at present:—Ships of all sorts employed, 1375; value of produce, L.318,517; men, 7753; annual expenses, L.284,783.

Commerce. The Hollanders, though placed, apparently, under circumstances the most unfavourable for the accumulation of wealth, overcame one difficulty after another with matchless perseverance, until they rendered their country the centre of European commerce, and diffused opulence and a taste for conveniences and enjoyments among the lowest orders of the people. In 1602 the Dutch East India Company was formed, and the Indian trade increased rapidly in magnitude and importance. Ships fitted both for commercial and warlike purposes were sent out. Amboyna and the Moluccas were wrested from the

Portuguese. Factories and fortifications were established from the mouth of the Tigris along the coasts and islands of India, as far as Japan. Alliances were formed with the native princes. In Ceylon, Malabar, and Coromandel, the Dutch were themselves the sovereigns. Batavia, in the large and fertile island of Java, formed the centre of their Indian commerce. In 1621 the Dutch formed a West India Company. Within the short period of 15 years this association conquered the greater part of Brazil, fitted out 800 trading and warlike ships, and captured from the Spaniards and Portuguese 545 ships, which were supposed to be worth L.7,500,000. In 1651 they founded the colony of the Cape of Good Hope. Between the years 1651 and 1672, when the republic was invaded by the French, the commerce of Holland seems to have reached its greatest height. Not by means of any artificial monopoly, but by the greater number of their ships, and their superior skill and economy in all that regarded navigation, the Dutch engrossed almost the whole carrying trade of Europe. In 1690 Sir William Petty estimated the whole shipping of Europe at about 2,000,000 tons; that of the Seven United Provinces being then, according to him, 900,000 tons. The necessities of the Hollanders, and the central situation of their country, no doubt directed their views to navigation and trade; but to account for their astonishing success in commerce, we must refer to moral causes. Without that free system of government, that toleration of all religions, and that perfect security of property which they early, and for a while almost exclusively, enjoyed, the Dutch could not have figured as they have done among the nations of Europe. The intolerance, the persecutions, and the folly of their neighbours, drove many of their most valuable and intelligent citizens to seek an asylum in Holland, where they established trades, manufactures, arts, and sciences. From the beginning of the eighteenth century the commerce of Holland gradually declined. This was owing to the growth of commerce and navigation in other countries, especially in England, and to the increase of taxation caused by the unavoidably heavy expenses incurred in the construction of the vast works required to confine the rivers and to keep out the sea, and by the heavy cost of the wars in which the republic was engaged. As a subordinate cause contributing to the decline of Dutch commerce, may be reckoned the subjection of the trade with India to the trammels of monopoly. The directors of the East India Company did not exert themselves to carry on an extensive trade with moderate profits, but to have a limited trade with enormous profits. Unlike their countrymen engaged in other branches of commerce, this company made no efforts to prosecute trade on fair mercantile principles. Their whole object was to exclude competition, to grasp at the monopoly of particular products; and when they had obtained it, they took care, by narrowing the supplies brought to market, to raise the price of their own articles to many times their real cost.

During the 20 years from 1794 to 1814, when the country was subjected to France, the foreign trade was annihilated, and the intercourse with the colonies was suspended; and it has been estimated that more than L.100,000,000 sterling, besides the expenses of government, were extorted from Holland by their acute masters. This is said, however, to have been met by such rigid parsimony on the part of private individuals and families, that the actual capital of the country was little, if at all, impaired by the extortion. On the return of tranquillity, the capital thus reserved was in a great degree employed in loans to the several foreign states of Europe; and these loans were made on terms so advantageous to the lenders, that, in the course of another period of 20 years from 1814 to 1834, more gain was made by the Dutch capitalists than had been taken from them in the preceding equal period. This traffic in money, of which Amsterdam may be considered as the central market for the whole of Europe, is not confined to the great capitalists, as in most other countries, but, by various modes, is so diffused over the community that those who have but small reserve funds are enabled to partake of the advantages of it, without having their attention withdrawn from their regular and customary occupations.

With the return of peace the intercourse had been renewed with the colonies in the East Indies and in South America, which had been restored to their former possessors in an improved condition. A new East India Company was formed, free from the erroneous principles that guided its celebrated predecessor. It still carries on a great, but not an exclusive trade. The old monopoly, with its long train of abuses, is now wholly abolished throughout all the Dutch possessions in the East. Proprietors of estates and villages, who have lands assigned to them by government, are obliged to furnish to its agents a certain quantity of spice, or of some other article, at a fixed and reasonable price, as a land-tax or rent. But this is the only obligation imposed on them. In all other respects they are quite free to act as they please; and hence these colonies have made extraordinary progress since 1815. While thus a profitable commerce with South-Eastern Asia was re-established, the proprietors of estates in Surinam were also enabled to realize their property. The fisheries, the transit trade, the commerce with the Baltic, and with the Peninsula and the ports of the Mediterranean, were all reopened. During the continuance of the union with Belgium, that part of the kingdom shared these branches of traffic, chiefly through the noble port of Antwerp. But the revolution which separated Belgium threw back the greater part of the commerce into the hands of the Dutch, and left the northern kingdom in possession of all the colonies. The most substantial of the merchants and the larger shipowners removed from Antwerp to Rotterdam or Amsterdam, and the trade of Holland has greatly benefited by the separation of the two countries.

From the tables of commerce and navigation published by government, it appears that in 1853 the total value of imports was L.26,754,311, about L.138,333 less than in 1852; and of exports, L.22,733,472, about L.25,000 more than in 1852. The total value of the transit trade was L.9,846,542, about L.225,000 more than in 1852. The following table will exhibit the proportions in which this trade was distributed among the different countries of the world:—

COUNTRIES.	IMPORTS.		EXPORTS.	
	1852.	1853.	1852.	1853.
	L.	L.	L.	L.
1. GREAT BRITAIN	6,954,833	7,324,667	5,085,167	6,164,083

Australia	...	...	...	57,917
	...	5,930,083	1,604,166	1,909,917

Butter and cheese figure among the great articles of the industry and the commerce of Holland. It appears, from one of the published tables, that from 1803 to 1850 the export of butter has constantly increased, so as to have been quadrupled in half a century. From 3437 tons in 1803, it arrived at 11,931 tons in 1852. The export of cheese was 9823 tons at the beginning of the century. In 1852 it was 19,646 tons.

For 1854, instead of a general statement such as the above, we have found indications regarding particular commodities, the trade in which was very active. The importation of raw sugar in 1854 was 108,546 tons, against 102,101 in 1853. The export of raw sugar rose to 55,536 tons, being 4420 tons more than in 1853. The importation of coffee from Java, on the other hand, was less in 1854 than that in 1853 and 1852. In 1852 it was 1,073,838 bags; for 1853, 938,680 bags; and for 1854, only 928,230 bags. The trade in indigo, however, was progressing. The imports in 1854 were 14,130 chests, against 10,200 in 1853; 8600 in 1852; and 5500 in 1851. The importation of cochineal was equally increasing—1535 chests in 1854 against 868 in 1851. Tobacco held also a principal place in the imports of 1854. There were received 13,550 barrels from Maryland, and 3110 from Virginia. Tin from Banca furnished 132,864 blocks. The trade in wool revived, and that in cotton assumed considerable importance. The trade in flax was 1611 tons in 1854. In 1850 it had not reached 344 tons. Thus it had been quadrupled in five years.

The account of exports is not for the same period so favourable. It gives indeed the first notice of direct trade with Australia, but the result of this new enterprise was not encouraging. Holland exported its agricultural produce, however, in great quantity. In 1854 the export of butter was 14,244 tons, against 13,261 in 1853. That of cheese was nearly 25,540, being 982 more than in 1853. That of cattle, 77,198 head of oxen. In 1853 there were 83,074 oxen and 204,148 sheep.

Shipping.

The following account is given of the shipping:—

	Cleared inwards.		Cleared outwards.	
	Ships.	Tonnage.	Ships.	Tonnage.
1850	6961	1,099,671	7031	1,136.664
1851	6960	1,166,140	7177	1,216,558
1852	7457	1,249,728	7712	1,317.425
1853	6883	1,151,293	7068	1,215,869

The Netherlands' and foreign ships were in 1853 in the following proportions:—

	Cleared inwards.		Cleared outwards.	
	Ships.	Tons.	Ships.	Tons.
Netherlands' flag	49½ p. cent.	44½ p. cent.	47½	43
Foreign	50½ ...	55½ ...	52½	57

To have a full view of the trade of Holland, we must not only learn its state as carried on by sea, but also by the rivers, which carry a great amount of it. Tables have been published of the merchandise which arrived and was forwarded by way of the Rhine in 1854. There was an increase above 1853 of 7260 tons from Amsterdam to places on the Rhine, and of 12,328 tons from the Rhine to that city. Coffee, rice, and the oleaginous grains are foremost in this progressive increase. The export of rice to Germany has had a remarkable increase. In 1842–52 it was only 8666 quarters per annum. In 1853 it was 46,459. The quantity of grain sent from Amsterdam to the Rhine in 1834 was 15,600 tons.

The vessels engaged in the river navigation were in 1853:—

	Cleared inwards.		Cleared outwards.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Laden	15,973	1,134,748	9844	787,105
In ballast	2,213	148,680	8187	521,975

with 127 wood-rafts, measuring 24,328 cubic ells.

The proportion of these belonging to the Netherlands was:—

Of laden vessels	8879	Tonnage	611,578	cleared inwards.
...	4615	...	376,009	cleared outwards.

The remainder belonged principally to Belgium and Prussia, and in smaller proportions to Hanover, Baden, Nassau, Hesse, Bavaria, Frankfort, and Wurtemberg.

On the 31st December 1853, the merchant fleet of Holland counted in all 2037 vessels = 239,601 lasts burden. There were 142 frigates = 56,142 lasts; 334 barques = 93,091 lasts; 66 brigs = 8439 lasts; 168 schooners = 13,436 lasts; 783 koffs = 46,465 lasts; 250 tjalks = 7259 lasts.

The number of steamers belonging to the Netherlands in 1837 was only 30, with 58 engines of 2200 horse-power. In 1853 there were 100 steamers, with 118 engines of 6911 horse-power, not including those of the royal navy. It is stated in the tables that, independently of the Netherlands' trade, there were employed during 1853 in the carrying trade between foreign parts, Netherlands' ships which made no less than 2266 voyages, with 207,204 lasts of lading. The Dutch consuls at foreign ports furnished the data of this enumeration, which was made in 1853 for the first time. In connection with the great emigration to the gold fields of Australia more than 50 Dutch ships were freighted in different British ports for that distant country during the first six months of 1854.

To these details, gathered from the statistical publications of the Dutch government, by which it has been attempted to convey an idea of the present state of the trade of Holland, we will only add one remark, that with the exception of the old East India Company's monopoly above mentioned, the commercial policy of Holland for a lengthened period was more liberal than that of any other nation. The same enlightened policy, if partially departed from during recent years, has been again cordially entered into after the recent example of Great Britain. A law enacted on 1st Sept. 1854 abolished the import duties on a great number of articles of merchandise, and the Netherlands' tariff thus modified, equals, if it does not even surpass, in liberality all other tariffs in existence. It has evidently been in consequence of this enlightened policy having for many generations been generally understood and practised by the Dutch government, that a country not more extensive than Wales, and naturally not more fertile, recovered, indeed, in a great measure from the waters, and kept from being again submerged by constant watchfulness and a heavy expenditure, accumulated a population of more than three millions, maintained wars of unexampled duration with the most powerful monarchies, and besides laying out immense sums in works of utility and ornament at home, lent hundreds of millions to foreigners. Notwithstanding their want of native timber and iron, they are abundantly supplied with all the materials of carpentry, ship-building, and manufactures. And though their commerce, notwithstanding its revival in later years, is much diminished from its earlier pre-eminence, the Dutch, even at this moment, are the richest and most comfortable people of Europe.

Army and navy.

The army and navy force amounted on the 1st Jan. 1840 to 40,265, in 1845 to 24,563, and in 1850 to 21,418 men. Thus the forces were in the course of ten years diminished by 18,847. This diminution is explained by the change of circumstances in relation to Belgium. The state of the army, as shown in the budget of 1853, was as follows:—

Arms.	On permanent duty.	During 3 mths.	During 1 mth.	Reserve.
Infantry	12,807	5964	...	23,924
Cavalry	2,970	...	...	1,272
Artillery	4,272	130	...	4,599
Engineers	439	60	60	206
	20,488	6154	60	30,001

The contingent for the militia in 1853 was 8834; the force of the communal guard (Schuttery) over the whole kingdom on 31st Dec. 1853 was 83,253, of which number 24,790 were in active service, and 58,463 in reserve.

In 1853 The Netherlands' fleet was composed of 5 ships of the line, 13 frigates, one of which had steam-engines, 13 corvettes, two of which had steam-engines, 11 brigs, 13 schooner brigs, one of which had steam-engines, 7 schooners, 17 steamers, 2 transports, 58 gunboats, and 3 vessels serving for exercise, barracks, or hospital; besides 3 steamers, of 206, 150, and 100 horse-power respectively, equipped by the navy department for the service of the colonies. The number of guns carried by these different ships-of-war varies from 84 to 74 for ships of the line, from 60 to 28 for frigates, from 28 to 12 for corvettes, from 8 to 12 for brigs, from 8 to 5 for schooner brigs, and from 10 to 1 for schooners. There were thus 145 vessels in all, of which there were, on the 1st Aug. 1854, employed in actual service—

The principal fortresses are Maestricht, Breda, Bergen-op-Zoom, Bois-le-Duc, Vlissingen, and the Helder.

Government. The form of government is prescribed by the fundamental law which was adopted by an assembly of 500 notables, called together as representatives of the nation by the Prince of Orange at Amsterdam in 1814. In 1848 it received important amendments. According to this magna charta of the Dutch nation, (1.) all the inhabitants of Holland, resident foreigners as well as natives of the country, have right to protection of person and property. Admission to offices and employment is open to all Netherlanders without distinction. The press is free; the rights of petition and of assembling are recognised.

Royal family. (2.) The crown is hereditary in the House of Orange. Male heirs are preferred, but females are not excluded. The king may not accept any foreign sovereignty except that of Luxemburg. The civil list is regulated anew upon every accession. In the present reign its amount is L.66,667. The eldest son of the king bears the title of Prince of Orange. The king, on accepting the government, takes an oath to observe and maintain the fundamental law. This oath is taken in an assembly of the states-general, convened for the purpose of his inauguration, in the city of Amsterdam as being the capital of the kingdom. The person of the king is inviolable; his ministers are responsible. The executive power is vested in the king. He has the direction of the external relations of the state. He declares war, and concludes peace and other treaties. He is not obliged to communicate them to the states-general if he shall judge that the communication would compromise the safety of the state. But without previously obtaining the permission of the states-general, he cannot ratify any treaty that would alter the limits of the kingdom. The king commands the army and navy, and appoints the officers. The administration of the colonies is committed to him. To him is also confided the management of the finances of the kingdom. He fixes the salaries of all employés, but pensions are regulated by special laws. He has the direction of the mint, and the right to confer titles of nobility. A Hollander may not accept foreign titles of nobility. Orders of knighthood are instituted by special laws. The king grants reprieves, abolition, and remission of punishment. It belongs to him to propose projects of law to the chambers. He can dissolve them when he pleases, but must command new elections in the course of forty days thereafter, and convene the new chambers in the course of two months.

Council of state. (3.) There is a council of state presided over by the king. This council must be consulted regarding every project of law, and every measure of general interest. The king chooses the members of this council, and also the ministers or heads of the departments of administration. All his decrees must be countersigned by one or other of the ministers. The council of state consists at present of 8 members, with the addition of Prince Frederick of the Netherlands, the king's uncle. The vice-president receives a salary of 8000 florins. The other members have 5000 florins each. The ministerial departments are variously arranged from time to time. In 1855 they were the minister of the interior; of justice; of finances; of exterior; of marine; of war; of colonies; of Protestant churches and Jewish synagogues; and of the Roman Catholic Church. The ministerial salaries are at the same rate as those of the members of the council. There is no prime minister properly so called.

States-general. (4.) The states-general are composed of two chambers. The members of the first chamber are elected for nine years, a third of their number retiring every three years; but they may be re-elected. They are 39 in number. They are chosen by the several provincial states from the class who pay the highest amount of direct taxes. The king names a president for each annual session. The provincial states elect the members in the following proportions:—North Brabant 5, North Holland 6, Friesland 3, Drenthe 1, Gelderland 5, Zeeland 2, Overyssel 3, Limburg 3, South Holland 7, Utrecht 2, Groningen 2.

The members of the second chamber are chosen by electors, who must be Hollanders, twenty-three years of age, paying direct taxes from L.1, 14s. to L.13, 10s., according to the localities and circumstances of their several districts. The country is divided into electoral districts, on the principle of giving one representative to each 45,000 of the inhabitants. The number of members of the second chamber is at present 68, nominated from 38 electoral districts, each sending 1, 2, or more members, according to their population. Amsterdam sends 5 representatives, 25 other districts have each 2; 13 districts have only 1 each. The total number of electors in 1853 was 82,593, of whom, at the elections in that year, 56,177 gave their votes. In 1854 only 41,736 voted, or about one-half of those entitled. Members of the second chamber must be Netherlanders, in possession of all the rights of citizenship, thirty years of age or upwards. They are chosen for four years. Half of the members retire every two years, but may be re-elected. They ought to vote without consulting or being instructed by their constituents. Each receives a stated salary of L.166, 15s. per annum, with travelling expenses. The king chooses a president for each annual session. The ministers of state have right to sit and deliberate with both chambers, but no right to vote unless they have been elected members. The same individual cannot be a member of both chambers. A member of either chamber cannot be a member of the high court of justice, nor of the chamber of finance, nor a governor of a province, nor an ecclesiastic, nor a military officer on active service. If a member accept any office under government, he must vacate his seat unless re-elected by his constituency. The members cannot be prosecuted in a court of law for their sentiments expressed in the sittings of the chambers. The states-general meet every year at the Hague, ordinarily on the third Monday of September. Their meetings are usually public. On the death or abdication of the king, the chambers meet in 15 days without having been summoned. The sessions of the states-general are opened and closed by the king either personally or by commission. On these occasions the two chambers assemble together, and the president of the first chamber presides. The annual session must be of at least 20 days' duration. The chambers cannot discuss any business unless more than half their members are present. In every question there must be an absolute majority. If the votes are divided, the question is resumed at another sitting. Votes are given *viva voce*, except in electing to offices, when the ballot is resorted to.

The legislative power resides in the king and the states-general. Projects of law made by the king, are first debated in the different sections, before being publicly discussed. The second chamber has the right of making amendments. A project of law, when adopted or amended by the second chamber, is by it transmitted to the first chamber. The states-general have right to offer projects of law to the king, but these must always originate in the second chamber.

The law fixes the annual budget, along with the ways and means. Each head of the budget must contain the expenses of one department only of the administration. The ministers give account of the receipts and expenses of each department, by presenting to the states an account previously approved by the chamber of finance.

Provincial states. (5.) The states-general are so called in contradistinction to the provincial states, which are legislative and administrative councils for the several provinces. The latter, besides electing the members of the first chamber of the states-general, exercise other important functions. They are charged with the execution of the laws of the kingdom within their limits, and have power (with the sanction of the king) to make particular laws for the several provinces. They have also considerable funds under their control, possessing power to levy taxes with the concurrence of the general legislature. They have charge of the embankments and other hydraulic works within their limits. They also co-operate with the general government for the promotion of religion, education, the maintenance of the poor, agriculture, manufactures, and trade. Whatever, indeed, relates specially to the internal police and government of the provinces is left to their regulation and decision. The king appoints a governor or commissioner to preside over their meetings and to observe their proceedings. They appoint a permanent commission to administer affairs during the intervals of their sessions, and to carry on the ordinary business of the provincial government. The members of these provincial states are elected directly by the parliamentary constituency of each province for a term of six years. One-half retire every three years. The same individual may not be a member of the states-general and of the provincial states at the same time. These councils assemble regularly twice every year. Their meetings are public. The number of members of the states of the provinces, severally, is as follows:—North Brabant 64, Gelderland 62, South Holland 80, North Holland 72, Zeeland 42, Utrecht 41, Friesland 50, Overyssel 47, Groningen 45, Drenthe 35, Limburg 45.

Communal councils.

(6.) The provinces are again subdivided into communes, each having a local administration, the composition and the powers of which are regulated by special laws according to the circumstances of each. At the head of this administration is a council, whose members are elected by the inhabitants for a certain number of years. To be an elector for the communal council requires payment of only half the amount of direct taxes necessary for an elector to the general or provincial states. The king names the president or burgomaster. The communal council superintends the interests of the commune, with reservation of certain points which must be submitted to the states of the province. They must submit the account of receipts and expenditure to the provincial states. The law establishes general rules for the communal administrations, but in imposing, changing, or abolishing local taxes (which the several communes have also the right of levying within their respective limits) the royal sanction is required. These communes include the cities and towns as well as villages and country districts.

The communes are,—In North Brabant 185, including 10 cities; in Gelderland 118, including 15 cities; in South Holland 234, including 13 cities; in North Holland 145, including 11 cities; in Zeeland 116, including 19 cities; in Utrecht 91, including 6 cities; in Friesland 43, including 11 cities; in Overyssel 62, including 3 cities; in Groningen 57, including 1 city; Drenthe 33, including 3 cities; in Limburg 125, including 5 cities: in all, the communes are 1209, including 87 cities. The cities, however, and the other communes are all locally governed in the same general manner; each country district having its burgomaster with his council, much the same as a city. The burgomaster and other magistrates receive salaries, as do also the governors and other officials of the provinces.

Revenue.

The following is the budget of receipts and expenditure of the national revenue for 1856:—

REVENUE—	
Direct taxes (land tax, provincial taxes, patents)	L.1,597,378
Excise	1,395,871
Stamps, registrations, hypothec successions	958,525
Import, export, and navigation duties	352,664
Duty on pawned gold and silver wares	19,158
Domains	108,975
Post-office	120,833
Lottery	33,333
Sporting and fishing licenses	7,083
Duty on mines	96
Diverse revenues	102,475
Interest of national debt contributed by Belgium	33,333
Interest at the charge of the colonies	900,000
Balance derived from colonial administration at home	391,667
Derived from sale of the national domains	77,864
Total	L.6,099,255

EXPENDITURE—	
1. King's household	L.66,667
2. High departments of state	45,688
3. Department of foreign affairs	40,834
4. Department of Justice	212,225
5. Home department	471,642
6. Reformed and other Protestant churches and Jewish synagogues	141,180
7. Roman Catholic church	49,246
8. Department of marine	634,715
9. Interest of national debt	2,935,586
10. Department of finance	530,159
11. Department of war	973,750
12. Colonial department	9,645
13. Incidental expenses	8,333
Total	L.6,119,670

The following table gives the receipts and expenditure of the different provincial governments for 1855:—

	Receipts.	Expenditure.
North Brabant	L.60,925	L.60,363
Gelderland	11,258	11,258
South Holland	19,928	19,928
North Holland	20,524	20,525
Zeeland	9,848	9,848
Utrecht	5,604	5,603
Friesland	28,787	28,777
Overyssel	16,429	16,429
Groningen	26,727	26,721
Drenthe	4,661	4,661
Limburg	6,369	6,369
Total	L.211,060	L.210,482

Further, the statistical publications of last year give the following budget of the communes for 1854:—

	Receipts.	Expenditure.
North Brabant	L.96,328	L.87,563
Gelderland	119,570	121,693
South Holland	366,725	364,831
North Holland	421,025	424,820
Zeeland	75,981	75,937
Utrecht	59,713	59,687
Friesland	124,361	130,436
Overyssel	92,804	89,424
Groningen	109,684	109,597
Drenthe	19,863	19,846
Limburg	51,171	40,972
Total	L.1,530,225	L.1,524,806

In consequence of the provincial and communal councils having right to levy taxes as well as the general government, it is necessary to sum up all the three budgets in order to obtain the whole amount of the public revenue and expenditure. This can, however, only be done for 1854, as the communal budgets for 1856 and 1855, and the provincial for 1856, are not given in the latest statistical publications:—

	Income.	Expenditure.
National	L.6,656,056	L.6,936,842
Provincial	176,345	176,665
Communal	1,536,225	1,524,806
Total	L.8,368,626	L.8,638,313

Justice.

Justice is administered in the king's name. There are codes of civil, commercial, and criminal law, of civil and criminal procedure, and of the composition of the judiciary body. The law also regulates military justice as well in the army as in the communal guard (Schuttery). No one can be deprived of his possessions unless on account of the public good, and then on receiving indemnification, except in case of war or inundation. The law indicates the judges. No one can be arraigned before a different judge from the one whom the law has appointed to try the case. The law regulates the mode of terminating differences which may arise between the administrative and judiciary powers. No one can be arrested without an order from a judge containing the reasons for the arrest. This order must be shown to the delinquent as promptly as possible. If, in extraordinary circumstances, a citizen is arrested by the political power, he who has given the order must inform the judge of it immediately, and deliver the person to him within three days. No one may enter the dwelling of another against his will, unless by order of some power authorized by law. Confiscation is forbidden. Every sentence must include the grounds of judgment, and specify the points of law on which it is founded. It must be pronounced in public. Under the sanction of the king, the administration of law and justice is confided to various courts.

1. The High Court of the Netherlands. The king selects the judges of this court from a list of three candidates for each vacancy presented to him by the second chamber of the states-general. The king chooses the president from among the members of the court. With the president it has a vice-president and twelve puisne judges. Members of the states-general, heads of ministerial departments, members of the council of state, governors of provinces, and other high functionaries, are amenable to this tribunal only. All causes in which the king, the members of the royal family, or the state, are defenders, must be tried before this court. It is the court of ultimate appeal, and superintends the execution of the laws by the lower courts. Its judges are appointed for life. They are divided into two chambers, one for civil and the other for criminal causes.

2. Next in order are the provincial courts. Their judges are appointed by the king from lists of candidates presented to him by the provincial states. These judges are also appointed for life. The provincial court of South Holland, seated at the Hague, alone is divided into two chambers, one for the trial of civil and the other of criminal causes.

3. Subordinate to the provincial, there are district courts in the several provinces (arrondissements or regtbanken). These district courts have from 5 to 14 judges each. including the presidents.

4. These arrondissements are still farther divided into cantons, each having a local court of its own.

5. The high military court has its seat at Utrecht, and has 14 judges.

In 1853 the high court had 369 criminal causes, the provincial courts, 1250; the arrondissement courts, 12,482; the canton-geregten, 11,595; and the high military court, 361. Of civil causes the high court had 119; the provincial courts, 454; the arrondissement courts, 4469; the canton-geregten, 7391.

In 1853 there were the following prisons:—8 for criminals, 12 for confinement in civil and military cases, 22 houses of arrest, 174 houses of detention. These on 31st December 1852 contained only 4087 inmates.

The prison at Rotterdam for juvenile delinquents of the male sex under eighteen years of age, and that for those of the female sex of the same age at Amsterdam, merit special notice. They receive all juvenile offenders from all parts of the kingdom. The number of males incarcerated at one time has varied from 84 to 116. These prisons are in effect schools under admirable management, connecting the branches of ordinary school education with religious instruction, according to the several professions of the childrens' parents, and with industrial training. When their period of imprisonment expires, they are not turned out to the streets to fall into the commission of new crimes, but are placed as apprentices or workmen, where they will be strictly attended to, and for two or three years they remain, to a certain extent, under the surveillance of the police.

Church.

According to the fundamental law, full liberty of religious profession is allowed to every one; but there is a right of *observation* asserted for the civil power, lest sects should arise which, under the name of religion, might seek to subvert the order of society. Equal protection is accorded to all religions recognised by the state. The members of the different churches and sects enjoy equal privileges as citizens, and have equal right to all public employments and all dignities. The statistics of 1854 give the following distribution of the population, according to their religious professions:—Protestants, 1,935,422; Roman Catholics, 1,201,891; Israelites, 62,610; religion not ascertained, 1,479.

Of the Protestants, about 1,700,000 still adhere to the Reformed Church which was established in Holland after the separation from Spain, and being then taken into the closest alliance with the states, obtained many privileges. It no longer enjoys an exclusive establishment, as salaries are now paid by the state to the ministers of various sects, and even to the Jewish rabbis. But the Reformed Church has still much the largest share of such benefits, including the king and the greatest body of the people among its members and adherents, and also receiving pecuniary supplies from the state twice as large in proportion to the number of its members as are accorded to other denominations. The Reformed Church of the Netherlands continues to hold the *Confession of Faith*, *Catechism*, and liturgical formularies, drawn up according to the doctrines of Zuinglius and Calvin, which it received at the Reformation and in the immediately succeeding age. The form of government is still Presbyterian, in accordance with the Calvinistic institution, so far as the jealousy of ecclesiastical rule, always manifested by the civil authorities of Holland, has allowed it to be carried into effect. The following resolution of the first National Synod held at Dort in 1578 lays down the basis of the church government:—"To establish good and legitimate order in the church, it is resolved that four sorts of ecclesiastical councils shall be instituted,—1. The consistory in each congregation. 2. The classis. 3. The provincial synod. 4. The general or national synod. In these assemblies only ecclesiastical affairs shall be transacted. As regards matters that are partly ecclesiastical and partly political, these shall be settled by consultation between the civil and the ecclesiastical authorities."

1. The consistories were composed of ministers and elders of each congregation, the latter selected from the heads of families, and appointed for a limited term, generally two years, but allowed to be re-elected. They managed the discipline and other spiritual matters of the flock. There were deacons similarly appointed to take charge of the poor. These were not constituent members of the consistories, but were allowed to take part with the elders in the calling of ministers.

2. The classes were composed of the ministers of several contiguous parishes, together with one elder from each. There was an appeal from the consistories to the classes. They also originated measures for the general interests of the parishes and had charge of the ordination of ministers.

3. The provincial synods consisted of two ministers and two elders from each classis within the province, together with correspondents from the synods of the neighbouring provinces. They assembled once every year, when they could obtain permission of the civil states of the provinces. But this permission was not seldom withheld. They usually had representatives of the states, called commissaries politic, present during their deliberations. These did not vote as members, but attended on purpose to *observe*, and doubtless to influence their proceedings. There was an appeal from the classes to the provincial synods. They had charge of the trial and license of candidates for the ministry.

4. From the provincial, there was again an appeal to the national synod, which consisted of two ministers and two elders, commissioned not from each classis, but from each provincial synod, to whom also foreign divines were sometimes joined. These national synods were assembled at irregular intervals when affairs of interest to the whole church had to be transacted. At the first, at Dort, in 1578, above referred to, it was resolved that such general synods should be convened once in three years. Accordingly, another was held at Middelburg in 1581. The next took place at the Hague, but not before 1586. No other was assembled for more than 30 years, until the celebrated synod of Dort in 1618. And that was the last which was held until after the restoration of the sovereignty to the House of Orange in 1816. These church courts had, indeed, considerable powers, but different in different provinces, as conceded or prescribed by the provincial governments. They were entitled to maintain order in the congregations, to exercise discipline on offenders against the laws of religion and morality, to compose differences and disputes between congregations and their ministers, to debar unworthy members from the Lord's Supper, and, if necessary, to excommunicate them. Classes and synods could suspend ministers, with suspension also of their stipends, and, if necessary, depose them. But they were overruled in the exercise of these powers by the civil authorities, who often prescribed rules to the ecclesiastical courts. Even when these came to a unanimous finding on points effecting either whole congregations, or ministers, or individual members, the party deeming himself aggrieved by their decision could always appeal to the judgment of the states of his province, by which the ecclesiastical sentence was not unfrequently reversed. During the twelve years of French ascendancy, this system of Presbyterian Church government in Holland fell into total disorder. It was remodelled in 1816 under the *observation* of William I., and, in some respects, greatly improved, yet so as not yet to enjoy any high degree of that spiritual independence demanded by the principles of Calvinism. The four graduated courts were restored to the consistories without any alteration in their constitution. The classes were restricted to one meeting annually, and (with the exception of the management of their ministers' widows fund) limited in their deliberations to the choosing of deputies to the provincial synods, and of a small committee called moderators, to whom were entrusted all the other duties and functions of the ancient classes. The provincial and general synods were restored to nearly the same position as under the ancient rule, with the advantage, however, of being allowed to meet at regular intervals, and to transact their appointed business without interruption from the civil power. The general synod, accordingly, has met every year since 1816 at the Hague, usually for 14 days. This court has the supreme direction of all the affairs of the Netherlands' Reformed Church, frames all the general regulations relating to its government, worship, and discipline, and has alone the power to depose ministers and excommunicate unworthy members. This modification of Presbyterian

government, though more orderly than that which preceded it, and free from the tendency by which that was characterized to tumultuous discussions and collisions with the civil power, did not prove upon the whole satisfactory to the Church. The very limited numbers composing all the higher administrations failed to secure confidence in and respect for their decisions; and the constant *observation* of the head of the state, although he asserted no right of positive interference, was regarded as inconsistent with religious liberty. A secession of members, at first attended with some disorder and tumult, and interference of the civil power in a manner that had much appearance of religious persecution, was, more than twenty years ago, the effect of this dissatisfaction. In recent statistics, the seceders are numbered 42,619. A more popular system of church government was demanded by many who still remained in the communion. When, in 1848, alterations began to be made in the fundamental law of the states, the church was also invited by William II. to revise its constitution, and to consider what changes in the mode of its government would be useful and satisfactory. This important affair was taken up by the church courts with great deliberation, and excited much interest among the members. Various changes have been made, and others proposed; but the whole cannot be considered as yet settled and arranged. The church courts are still constituted pretty much as they were from 1816 to 1848; and the community is not yet disposed to acquiesce in and be satisfied with their organization and proceedings. They are loudly accused, in religious periodicals, of too great remissness in dealing with preachers of erroneous doctrines at variance with the old Calvinistic *Confession*, and even of setting the old standards aside by their positive decisions. But whether these accusations are founded on fact, or the result of undue jealousy and suspicion, it is certain that the spirit of true and enlightened Christianity has mightily revived of late years, both among the clergy and people of the Netherlands' Church. For details we would refer the reader to *A Brief View of the Dutch Ecclesiastical Establishment*, by the Rev. W. Steven. D.D., Edin., 1839.

There are 1637 ministers in the Reformed Church of Holland, not including 25 ministers and 8 emeriti of the Wallon Synod, which is also represented in the General Synod of the Netherlands' Reformed Church. To these must be added 13 professors of theology in the universities and Athenæum, making in all 1683 clergy; while 4 ministers of the Scotch Church, 1 English Presbyterian, and several German Protestants are included in the numbers composing the Dutch classes. Those ordained and sent to the colonies are,—in the East Indies, 21; in the West Indies, 7; making an entire total of 1711. The licentiates or candidates for the ministry are 92. Holland was even divided into dioceses of the Roman Catholic Church, by a papal bull of 4th March 1853. This proceeding on the part of the Bishop of Rome raised great excitement among the Protestants of Holland, and a law was made by which this Roman Catholic hierarchical establishment was sanctioned and agreed to only on certain conditions. These conditions are, principally, a modification of the oath usually taken by Roman Catholic bishops at their consecration, a stipulation that none of them shall enter on their functions without the special license of the king, the taking of an oath of allegiance to the national government, and an agreement that the bishops shall reside, not in the cities from which they assumed their titles, but only in such places as are appointed them by the king. Accordingly, they have been all settled, according to the following scheme, in North Brabant and Limburg, where the greater part of the population is Roman Catholic.

Support of the poor.

The Hollanders are very liberal and charitable in their support of the poor. In general, the destitute are cared for by the deacons of the churches to which they belong. The communes give assistance, which is applied principally to those unconnected with any church. Official returns for 1853 make known the existence of 7410 charitable and benevolent administrations, of which 2900 relieve the poor at their own dwellings to the number of 418,318; 494 are hospitals, where the destitute are lodged; 59 are infirmaries; 41 lying-in hospitals; 163 are poor schools—the scholars 56,619: 2262 are schools, where the poor children are taught gratis, along with others who pay for instruction; 138 asylums; 2 institutions for the deaf and dumb; 2 for the blind; 40 institutions for employing poor labourers who can find no occupation; 47 for relieving poor travellers.

There are three great workhouses for the whole kingdom, into which all destitute persons who apply obtain admission—one at Amsterdam, another at Middelburg, and a third at Nieuwe Pekel A, near Groningen. Plain ordinary food, in no great abundance, is supplied to all, with clothing of coarse materials. There are looms and other implements of industry for those who will work, wages are paid to the industrious as means of purchasing such comforts as would improve their diet. The sexes are kept strictly separated. The inmates, while they continue such, are not allowed to go abroad; but they may at any time obtain their discharge on application to the governors. Those discharged on their own application cannot be re-admitted during the first month thereafter. These workhouses are very spacious, and, in times when employment is scarce, as during a severe winter, are resorted to by multitudes of the destitute. There have also been formed, in part by government assistance, but chiefly by voluntary subscriptions, several pauper colonies on waste lands on the borders of the Zuider-Zee. Poor families are settled there at their own request. At first they are provided with dwellings, implements of work, and means of subsistence for a limited period. They are encouraged to establish themselves by their own industry and frugality. A moderate sum, paid by instalments, is accepted as the price of their outfit, and ultimately of their houses and lands, which they are thus enabled to acquire in full property. They may then, if so inclined, dispose of them to new settlers, and return with their realized property into the general community. According to the returns above referred to, 665,000 indigent persons were, in 1853, succoured by the different charitable administrations, being at the rate of 208 for every 1000 of the population. The expense of all these charitable establishments amounted to L.1,125,000. L.694,445 were given to paupers for their subsistence; L.2,500,000 were absorbed in expenses of administration and board of pauper inmates. The expense of the pauper colonies amounted to L.208,334 more. The receipts were L.1,160,618. The sources of this income were—contributions from the communes, L.228,667; donations and collections, L.155,192; individual subscriptions, L.26,147; revenues of hospitals and other establishments, L.3,714,783.

Society for the Promotion of the Public Good.

Among the various benevolent institutions of Holland, special attention is due to the "Society for the Promotion of the Public Good," which originated in 1784 with John Nieuwenhuizen, a humble Baptist minister at Edam, assisted by a few benevolent individuals. It has now 220 branches throughout Holland, supported by 14,000 members, each paying a small yearly contribution. The amount and variety of good effected by this institution cannot be easily calculated. It has promoted the establishment of numberless schools, asylums, and works of public utility. It is feelingly alive to every interest of the population, especially the indigent classes. Pervading the whole country with its cheering influence, its sections hold fortnightly meetings, at which lectures and essays on useful subjects are delivered, questions (neither political nor polemical) of public utility are discussed, and good works of all kinds originated and provided for. As soon as one section has got 500 members, a new section is founded to be formed of those who shall afterwards join. Their meetings are reunions of the various classes in society, and are of great advantage in promoting intercourse and sympathy among all ranks.

Education.

Education is promoted in Holland under the general direction of the minister of the interior, by three universities—Leyden, Utrecht, Groningen, and the Athenæa of Amsterdam and Deventer; then by seminaries of an intermediate class, and special schools; and then by numerous primary schools. The University of Leyden possesses a library which has been greatly enriched of late years by donations from individuals, and by a judicious application of funds dedicated to that object; a botanical garden, to which Professor Reinwardt, who died in 1854, bequeathed his valuable herbarium; an archæological museum, where Javanese and Hindu monuments are found, along with German antiquities; a collection of papyrus and of Egyptian monuments; of Roman and Greek antiquities; a numismatic cabinet, remarkable for its collection of Lusitanian and Iberian coins; and a museum of natural history containing many rare specimens of animals from the far east and the Indian Archipelago. Such, along with the library, are the rich stores of this celebrated university. There are the four faculties of theology, medicine, law, and sciences. The Latin

University of Utrecht.

language is employed in most of the classes of theology, and also in several of the law and medical classes. The principles and the history of Roman law, and of the law of nations, are taught in Latin. Dutch is generally employed in teaching civil and commercial law, the history of diplomacy, and political economy. The law faculty of Leyden aspires to the credit of forming not only lawyers, but men enlightened as to all the interests of modern life. The faculty of medicine employing Dutch in the theoretical instruction, still keeps up the use of Latin for those practical lectures which are given beside the couches of the patients. The courses of scientific lectures are generally given in Dutch. Zoology and comparative anatomy are still taught in Latin. Oriental studies are prosecuted with ardour at Leyden. Professors and students rival each other in the zealous study and investigation of the literary monuments of the East, and especially of Arabia. The University of Utrecht has a library containing most interesting collections of theological writings. Along with the library are an anatomical museum, a chemical laboratory, an observatory in perfect order, and a botanical garden abounding in rare plants. In the instruction of Utrecht the theological is the principal faculty. This university educates numbers of Protestant ministers for the German provinces of the Rhine, where the system followed at Utrecht, which consists of combining classical with theological studies, is greatly approved of. In the other faculties Latin is also employed, side by side with Dutch, as at Leyden. The faculty of law at Utrecht directs the attention of the students not only to the essential elements of the Roman law, but principally to German law and the ancient customs of the country. The number of foreign students increases at Utrecht: in 1854 there were 18 students from the Cape of Good Hope.

The University of Groningen reckons among its principal resources a very good chemical laboratory. The use of Dutch and Latin in the delivery of lectures is regulated pretty much as at Leyden and Utrecht. The Athenæum at Amsterdam has a good library, a museum of natural history, a beautiful mineralogical collection arranged by Professor von Baumhauer, a botanical garden, to which, in the year 1854, 400 new species were added. This Athenæum supplies the means of instruction on a great variety of subjects. The Athenæum at Deventer, while it continues to provide well for instruction in the higher branches of knowledge, also affords the means of a commercial education. The number of professors at Leyden is—in theology, 5; law, 5; medicine, 5; science, 8; and literature, 10—in all 33, and one lecturer. At Utrecht—in theology, 3; in law, 5; medicine, 5; science, 6; and literature, 4—in all 23, and four lecturers. At Groningen—theology, 3; law, 3; medicine, 5; science, 5; literature, 5—in all 21.

The number of students on 31st December 1853 was as follows:—

	Leyden.	Utrecht.	Groningen.	Amsterdam.	Deventer.
Theology......	179	223	80	65	1
Law	270	179	97	44	7
Medicine......	134	66	70	25	...
Science.........	19	7	7	5	4
Literature.....	41	14	10	4	...
Total......	643	489	264	143	12

Total of university students, 1551. Total of degrees conferred in the university, in 1853–54, 149, distributed as follows:—Leyden, 60; Utrecht, 57; Groningen, 32; Amsterdam, 13; Deventer, 0.

Intermediate instruction was given in 1853–54, at 67 establishments (40 Latin schools and 27 gymnasia), training 247 masters and 1826 students. With these seminaries may be classed various special schools, viz.,—the royal academy for the army and navy at Breda. Practice is there combined with theory. The pupils for the navy make a tour of instruction of six weeks on board a brig. They visit the naval establishments of England, and cruise in the Atlantic. The pupils destined for the army form a camp on the heaths of North Brabant. This academy in 1854–55 had 308 students. There were admitted from it into the navy 21, and into the army 38. The royal academy at Delft trains engineers and functionaries for the East India service. In 1853–54 it had 154 students. The public school of military surgery at Utrecht in 1853–54 had 122 students. The clinical schools at Rotterdam, Amsterdam, Hoorn, Alkmaar, and Middelburg, had together 209 students. The veterinary school at Utrecht had only 7 students. In the same year the school of rural economy at Groningen, having a farm connected with it, gave theoretical and practical instruction to 30 pupils. A school for instruction in commerce and industry at Amsterdam, had 30 pupils. Schools of training for the merchant navy occupy a distinguished place among the educational institutions of Holland. The institution at Amsterdam for the merchant navy, had in 1854, 92 pupils—44 within the institution and 48 on a voyage. The technical school at Utrecht ought also to be mentioned, which gives scientific instruction to artisans, and is in a prosperous state. Nor would we omit the military schools, where practical instruction is given by under officers, superintended by lieutenants-adjutant. The pupils in these were 643.

Primary instruction was given in 1853–54 in 3374 schools, of which 2469 were public, and 905 private. The teachers in these were 7027, of whom 6329 were male, and 698 female teachers. The number of pupils was, 1st January 1854, 392,161; of whom 218,723 were boys, and 148,680 girls; on 15th July there were 321,850, of whom 173,170 were boys, and 148,680 girls. Thus the pupils attending the primary schools alone, amounted in winter to one-eighth, and in summer to one-tenth, of the whole population. Allied to these primary schools are others of particular sorts:—Infant schools, 612 in number, with 32,250 children. Boarding schools, 22 for boys and 17 for girls, the former having 594, and the latter 365 pupils. Boarding and day scholars, 196 for boys, and 88 for girls, having 4516, and 2869 pupils respectively. Repetition schools—designed for young persons who have finished the intended course of their education, and being now engaged in trades or otherwise, are encouraged to revise their studies in the evenings—136 in number, with 3199 male, and 1365 female scholars. Sunday schools 114, with 5000 male, and 4861 female pupils. Industrial schools 49, with 349 male, and 4792 female learners. Popular singing schools 129, with 3287 boys, and 2448 girls. Schools in the army for the common soldiers, having 177 teachers, with 2768 scholars. Of those aspiring to the rank of 2d lieutenant, and requiring scientific instruction, 304 additional pupils. Taking all the above numbers of pupils into the account; those studying at universities and the intermediate seminaries, together with the primary schools, and those others which we have noted as allied to them, we have of youths under instruction in Holland in January 1854, 466,100, being about 1 in 7 of the entire population. The primary schools (properly so called) are superintended by local boards, assisted by inspectors, of whom there are 70, or one for each of the school districts into which the kingdom is divided. In the general superintendence of the whole, the minister of the interior is assisted by an inspector-general. No person is allowed to open a school, or to act as an assistant schoolmaster, or even to give private lessons (except without fee or reward), until first he has received a certificate of his ability to teach, granted after examination by a board, consisting of inspectors. There are two normal schools for teachers, one at Groningen for the northern provinces, and the other at Haarlem for the centre and the south. In the primary schools the pupils are admitted without distinction of creeds, and no religious instruction, except a little Bible history, is given by the masters. Religious instruction is communicated to the scholars by ministers and catechists at separate hours, and often not in the schoolrooms, but at the houses of the clergymen.

Literature

In no country of Europe has the proportion of highly learned men to the whole population been so great as in Holland. Among many, including Thomas à Kempis and his pupil Agricola, whose writings exercised the most extensive influence, and who, by the wide diffusion of light, were precursors of the Reformation, Erasmus holds the highest place. He was born at Rotterdam, 1467, where a fine bronze statue of him, erected in 1622, still stands, and is accounted one of the chief ornaments of the city. Subsequently a great impulse to literature was communicated by William I., Prince of Orange, who, in 1575, founded the University of Leyden as a reward to that city for its brave defence against the Spaniards in the preceding year. Men like Scaliger, Lipsius, Heinsius, Gronovius, and Spanheim, in ancient learning; Erpenius and Gollius in Oriental literature; Gomarus, Arminius, Drusius, and Cocceius, in theology, extended their own fame and that of their university throughout the whole of Europe. Soon afterwards the universities of Franeker, of Groningen, and of Utrecht, produced a rivalry highly advantageous to the diffusion of knowledge. In the seventeenth century, Huygens, Leeuwenhoeck, Zwammerdam, and Hartsecker, were highly distinguished as astromers, and as natural historians. In the eighteenth century Albert Schultens, Hemsterhuis, and the celebrated Boerhaave, with many others, extended the study of the Greek and of the Oriental languages, improved their own, and more especially diffused a more correct knowledge of the healing art. The science of the law of nations, as well as of law in general. owes much to eminent Dutch writers; and nowhere has the research into antiquities been more assiduously pursued, or with greater success. The celebrity of Dutch literature, combined with political and polemical reasons to attract able men from other countries; and their works, published in Holland, still farther extended the renown of the Dutch schools. Thus Scaliger and Luzac, men of French origin; Albinus, Vossius, Gronovius, Ruhnken, and Vorstius, were Germans; and Wyttenbach was a native of Switzerland. Most of the works of these earlier Dutch writers were published in Latin for the sake of greater circulation. But a vast number of other writers who published in Dutch, though little known for that reason, beyond the narrow limits of their own country, are well deserving of a European reputation. Vondel, born in 1587, not only merited, but obtained such a reputation in his own time by his dramatic poems, *Palamedes*, *Gysbrecht*, *Van Amstel*, and *Lucifer*, the last of which has been characterized as the precursor of Milton's *Paradise Lost*, which it preceded by fourteen years, and which bears a surprising resemblance to it. Contemporary with him was Jacob Cats, a truly national and popular poet, who has addressed himself to all the best feelings of his countrymen, and whose works are still highly prized by Hollanders of all classes. Elizabeth Hoofman, or, according to her marriage name, Koolaert, born in 1664, was one of the most learned women, not only of her own, but of almost any other age or country. Besides several poems in Latin, she wrote in Dutch the *Schouwburg der Verwoesting*, which has enjoyed a lasting reputation. Van Effen, who was born in 1684, is one to whom the prose literature of Holland is most highly indebted. He has deservedly been called the Dutch Addison, not only as being a distinguished essay writer, but on account of the terseness and elegance of his style. Jan de Marre, born in 1696, contributed to the Dutch stage one of its best and most popular tragedies, viz., *Jacoba van Beyeren*. In 1710 and 1713, were born William and Onno van Haren. The former, author of *The Friso*, a romantic epopœia, possessing varied and distinguished merits. The latter, however, was of superior talents. He was author of *The Geuzen*, a cycle of national poems, celebrating the leading events in the history of the Netherlands. This is the chef-d'œuvre of the Dutch literature in the eighteenth century. In 1738 was born the Baroness Cornelia Juliana de Lannoy, who wrote excellent tragedies. Van Alphen, born in 1746, besides his poetry, has other claims to fame, as a moralist, a philosopher, and a critic. Admirable in themselves, his *Cantatas* have the further merit of being the first productions of the kind in the language, and are still unrivalled in it. P. L. van Kasteele, a friend of Van Alphen, wrote good original poetry, and showed considerable talent by his translations, among others his version of *Ossian* in hexameter verse. Arend Fokke, born 1755, stands without a rival in the language as a humorous and satiric writer. His "*Boertige Reize*" *Comic Journey through Europe;* and his *Ironical Comic Dictionary*, are celebrated. Feith Helmers and Bilderdyk, are writers who lived within our own time, and such as would do honour to any country. Feith, born 1753, is entitled to admiration both as a poet and a critic. His *Grave* is a masterly production. His *Thirza*, *Inez de Castro*, and *Lady Jane Grey*, exhibit his powers as a tragic poet; while his *Letters*, his *Essay on Heroic Poetry*, &c., place him in a high rank as a prose writer. Helmers, a merchant, born 1764, composed poems which breathe the most noble and generous sentiments. Bilderdyk, born 1756, exhibited his varied powers with equal success upon the most opposite subjects. His *Ondergang der eerste Wereld*, is a very fine poem, but unfinished. Helmers and Bilderdyk both died in 1813. Kinker, born in 1764, is another excellent poet, and has produced admirable translations from Schiller. Loots, Loosjes, Tollens, Immerzeel, Van Hall, Da Costa, Van Lennep, Beets, all of them now, or till very lately, living, are writers who do honour to the literature of their country. We will not, however, conclude, without honourable mention of van Kampen, who died in 1839, author of the *Beknopte Geschiedenis der Letteren*, &c., a most interesting work, from which much of the information above given has been derived.

Language. It is matter of great regret, that the above notice of Dutch writers, short and imperfect as it is, will be found longer and more complete than all but a very small minority of our readers will require as a guide in the selection of authors for their own perusal, owing to the almost universal neglect of the Dutch language by our countrymen. On the subject of this neglect of the language of the Hollanders, the writer just quoted expresses himself in terms severe, but scarcely more so than the case demands. The Dutch is a language derived from the same source with the German, and resembles the Anglo-Saxon in its declension. As spoken indeed by the common people, it sounds rather harsh to English ears, but scarcely more so, we believe, than provincial English does to foreigners. As spoken by well educated persons, it is euphonious and agreeable. It is of homogeneous construction, having great power of forming compounds and derivatives from native words, and not requiring, as English, to borrow terms incessantly from foreign tongues. Its plastic elements have also been most carefully wrought up and polished; nor have any people paid greater attention to purity of style and elegance of diction than the Dutch writers of late years. That devotional fervour, and that regard for the hallowing influence of domestic life, together with nobleness and independence of spirit which generally pervade the poetical and imaginative writings of the Hollanders, ought to have gained for them the attention of the British public.

Fine Arts. Amidst their fierce contests, and their eager pursuit of gain, the Hollanders have been munificent patrons of the fine arts, especially painting; and their artists have powerfully, but in a peculiar manner, rivalled those of Flanders and of Italy. The Dutch school of painting has been praised for the truth of its representation of natural objects, for its perfect finishing, its appropriate shading, and the colouring and delicacy of pencil; but it has been censured for its selection of unworthy objects. The founder of the school was Lucas of Leyden, born in 1494. His most eminent followers were, Van Been of Leyden, born in 1586, said to have been an instructor of Rubens; Bloemart of Gorcum, who painted historical pieces, landscapes, and cattle, and died in 1647; Cornelius Poelenburg of Utrecht, born in 1586, and died in 1663, who was peculiarly happy in his landscapes with figures; and his two distinguished pupils, Bertange and Haensberge; also Rembrandt, who, by his exquisite colouring, was enabled to hide all his other faults. Without enumerating their peculiarities, and without extending the list, we insert the following names, most of which are well known to those who have paid any attention to the history of painting and painters;—Zachtleben, Gerhard Terburg, Swanvelt, Asselyn, Gerhard Dow, Peter van Leer, Wouverman, Waterloo, Berghem, Paul Potter, Backhuysen, Mieris, Schalken, Jardin, Ruysdael, Van der Werff, and Van Hulst. To these we might add many even of recent date. Among the painters of the present day, Kruseman and Pieneman are highly celebrated. An extensive collection of modern paintings is kept in the palace called the Pavilion at Haarlem, itself a very beautiful work. Of ancient paintings there is one great national collection at the Hague and another equally celebrated at Amsterdam, containing most beautiful specimens of Dutch painting, but also rich treasures of Italian art. Holland is throughout very rich in paintings. With these not only the halls of palaces are adorned in profusion, but also those of townhouses, hospitals, and other public buildings, and the apartments of private houses even of middle rank. The Dutch have not equally excelled in statuary and architecture. These arts have been much cultivated among them, however, of late years. (J. I—M.)

HOLLAND, Dr Philemon, the "translator-general of his age," as he was called by his contemporaries, was born in 1551 at Chelmsford, in Essex. He was educated at the grammar-school of that town, and afterwards at Trinity College, Cambridge, of which he became a fellow. On being appointed to the rectorship of the free grammar-school of Coventry, he began that long series of translations from the classics which have saved his name from oblivion even to our own times. He also found time to carry on a very considerable practice as a physician. By a proper use and distribution of his time he reconciled his three professions of schoolmaster, doctor, and translator, fulfilling the functions of all three with undiminished vigour and assiduity till his eightieth year. He died in 1636, in the eighty-sixth year of his age. His chief translations are those of *Livy;* Plutarch's *Morals; Suetonius; Ammianus Marcellinus;* and the *Cyropædia* of Xenophon. He also did good service to literature by his edition of Camden's *Britannia*, to which he made some valuable additions.

HOLLAR, Wenceslaus, a celebrated engraver, was born in 1607 at Prague, in Bohemia. His parents, who were in good circumstances, intended him for the law, but they were ruined by the capture of Prague in the course of the Thirty Years' War; and the young Hollar, who had already given evidence of artistic skill, was apprenticed to Matthew Marian, a pupil of Rubens and Vandyck, to learn engraving. He was only eighteen years old when he published his first pieces, consisting of prints of the Virgin, the *Ecce Homo*, and some other pieces. Leaving Prague in his twenty-first year, he began a wandering life through Germany, taking views of the chief towns and of the most striking scenery of the Danube, Rhine, and other streams, which brought him great fame, but no regular employment. Even at this early period of his life his pieces were known for the exquisitely delicate touch and beauty of finish which they displayed. Hollar's fortunes were at a very low ebb, when he fell in with the Earl of Arundel (then on his way through Germany on an embassy to the Emperor Ferdinand II.), who attached him to his service. Soon after reaching England with his patron he was appointed to instruct the Prince of Wales in drawing; and in 1640 published his *Ornatus Muliebris Anglicanus, or the several habits of Englishwomen from the Nobilitie to the Countrywoman, as they are in these times*, a highly valuable and beautiful work. When the Civil War broke out Hollar was once more left to his own resources; and having incurred the suspicions of the parliament, he was thrown into prison. After a short confinement he made his way over to Antwerp, where Lord Arundel was then residing, and where he wrought quietly and assiduously for printsellers and publishers during several years. His pieces never having fetched prices at all proportionate to their merits he was obliged, in order to make a living at all, to put a value on his time. He fixed his tariff at fourpence an hour, which he marked by a sandglass. So exact was he, that when any one, even his employers, came to speak with him about the picture on hand, he always turned down his glass, charging payment only for the time he was actually engaged with his burin. It was in this humble way that he produced his fine engravings after Da Vinci and the great masters of portrait-painting. On returning to England after the Restoration, Hollar worked with the same unflagging industry, and with no more profitable result, than in his younger days. His plates in Dugdale's *Monasticon* and *History of St Paul's* attest his diligence. In 1669 he was commissioned by Charles II. to take plans and perspective drawings of Tangier and its fortifications, which, on his return to England, he engraved. His last known engravings are his unfinished illustrations of Throton's *Antiquities of Nottinghamshire.* These and other works brought the artist to his seventieth year, but without the independence he had struggled for all his life. On his very deathbed an execution was served upon his house. His last words were a petition to be allowed to die in his bed, and that he might not be removed to any other prison but his grave. It is not known whether this prayer was granted. The day of his death was the 28th March 1677. According to Vertue's *Catalogue* Hollar's works amount in all to about 2400 pieces. The best of these possess great spirit, lightness, and freedom of touch, combined with the most scrupulous accuracy. His delineations of still life in particular are admirable, but his figure pieces are generally not very happy.

HOLOCAUST, a sacrifice which is entirely consumed by fire. See Sacrifice.

HOLOGRAPH, a deed or testament written in the testator's own hand.

HOLSTEIN, a duchy of Denmark. See Denmark.

HOLT, Sir John, the celebrated Lord Chief-Justice of the Court of King's Bench in the reign of William, was born at Thame, Oxfordshire, in 1642. His father, Sir Thomas Holt, had been sergeant-at-law, and his eldest son John followed also the profession of law. After having been entered at Oriel College, Oxford, as a gentleman commoner, he became a member of Gray's Inn in 1658. He soon displayed a decided predilection for the study of law, became an able advocate, and well versed in the constitutional law of England. He was made Recorder of London in 1685, which important office he held with ability for a year and a half, when he became unpopular at court. It had been determined to abolish the test act; but the measure was opposed by Holt, and in consequence he had to retire from the office of recorder. Subsequently, however, in 1686, he was made sergeant-at-law. The ability which he displayed in the *Convention Parliament* raised him so high in the estimation of the Prince of Orange, that, upon the accession of the latter to the English throne, Holt was made Lord Chief-Justice of King's Bench. Upon the removal of Somers in 1700 from the chancellorship, William was desirous that Holt should accept the Great Seal, but he declined. He died in 1709, at the age of sixty-seven.

Sir John Holt as a judge was a model of unbending integrity. He persevered in what he knew to be right, irrespective of the opposition of both houses of parliament. For twenty-two years his great acquaintance with common law, and strict sense of justice, were devoted to the preservation of the rights of his countrymen against invasion from whatever quarter. His understanding was sound, and his skill in seizing the main points of a case amid a mass of details, as well as his great clearness in stating the case, were valuable qualities in a judge. His physical as well as his moral courage was at times exhibited. He had been requested to supply a number of police to help the soldiery in quelling a riot. He assured the messenger that if any of the people were shot he would have the soldiers hanged. He went himself, and prevented bloodshed. On another occasion he had declared in favour of the Aylesbury burgesses, who had been committed to Newgate for complaining about the non-registering of their votes. The House of Commons summoned him to appear before them; but as the summons was disregarded they sent the Speaker to him. Holt peremptorily told the Speaker that unless he returned immediately to his chair he would have him sent to Newgate.

Chief-Justice Raymond has given a report of Holt's decisions. Holt's character as a judge is highly spoken of in the *Tatler* (No. 14), under the name of Verus. The following reports were published by him in 1708, folio, with notes:—"A Report of divers cases in Pleas of the Crown, adjudged and determined in the reign of King Charles II., with directions for justices of the peace and others, collected by Sir John Keyling, knight, Lord Chief-Justice of the Court of King's Bench, from the original manuscript under his hand; to which is added the Report of three modern cases—viz., Armstrong and Lisle, the King and Plumer, the Queen and Mawgridge."

HOLT, a municipal and parliamentary borough of North Wales, Denbighshire, on the Dee, which is here crossed by an old bridge of ten arches. Some traces still remain of Holt Castle, which having been garrisoned for Charles I. was taken and dismantled by the parliamentary forces in 1645. Holt is governed by a mayor, two bailiffs, &c., and is a contributory borough to Wrexham. Pop. (1851) 1029.

HOLY ALLIANCE, The, a league formed by the principal sovereigns of Europe after the defeat of Napoleon at Waterloo. The basis of this alliance was drawn up by Alexander of Russia (Sept. 26, 1815), and received the signatures of Francis of Austria and Frederic William of Prussia. Its name, which was dictated in accordance with the popular religious enthusiasm of the time, was fitly expressive of the vague principles of religious charity and peace on which it professed to be based. It gained strength by the accession of England and France, but thenceforward became an alliance simply for the establishment of existing dynasties in Europe, as may be seen from the declaration of November 1819, and from the results of the congresses of Troppau, Laybach, and Verona. After the secession of England and France the holy alliance became practically obsolete.

HOLYHEAD (Welsh, *Caer Gybi, i. e.*, fort of Gybi), a parliamentary borough, seaport, and market-town of North Wales, on an island at the western extremity of the county of Anglesea. It is connected with the main part of the county by a vast embankment, three-quarters of a mile in length, and of an average height of 16 feet, with a bridge near the centre through which the tide rushes with amazing velocity and force. The town, formerly a small fishing village, has acquired importance in consequence of its being the nearest and most convenient place of embarkation for Ireland. It is the point of termination of the great parliamentary roads from London and Chester, and of the Chester and Holyhead railway, in connection with which steam-packets leave the harbour several times a-day for Kingston near Dublin. The vast amount of labour and money expended on public works connected with the harbour has materially contributed to attract and support an active and thriving population. Holyhead has been selected by government for a harbour of refuge. The works when completed will enclose an area of about 316 acres, with a depth of at least 6½ fathoms water. The church, occupying the elevated site of an ancient monastery, is dedicated to St Gybi; and in the south porch is a rude figure of the patron saint, under a canopy. The churchyard is partly surrounded by a very curious and interesting Roman wall. The pier extends nearly 1000 feet, and upon it is an arch of Mona marble commemorative of the visit of George IV. in 1821. At the extremity of the pier is a lighthouse, exhibiting a white light 50 feet above sea-level. On South Stack (Stack), an isolated rock 3 miles W., is another lighthouse connected with the harbour, and of essential service in facilitating the access. The light, which is 212 feet above high-water mark, is produced by 21 lamps with powerful reflectors. The inhabitants are chiefly engaged in the coasting trade and in shipbuilding. The coast is extremely wild and rugged, presenting numerous wave-worn caverns, which form the haunt of innumerable sea-birds. From the summit of Pen-Caer-Gybi, or the Mountain of Holyhead, 700 feet in height, a good view is obtained of the town and harbour. On the sides of the mountain are traces of extensive British fortifications, and at the top are remains of a circular building 10 feet in diameter, which was probably a Roman watch-tower. Market-day, Saturday. The borough is contributory to Beaumaris in returning a member to parliament. Pop. (1851) 5622.

HOLY ISLAND, an island, or rather a peninsula insulated at high water, on the N.E. coast of England, 9 miles S.S.E. of Berwick-on-Tweed. It was by the Britons called Inis Medicante, and also Lindisfarne, from the small rivulet Lindi or Landia, and *fahreen*, a recess. It received its present name from being the site of one of the earliest monasteries established in this country. It is connected with the mainland by sandbanks dry at low water, and affording a passage to vehicles of all kinds. It has an area of 3320 acres, but about one-half of its surface towards the N. is a sandy waste, abounding in rabbit-burrows. The rest of it, however, is very productive. At the S.W. angle of the island is a small village, formerly a town of considerable size. The ruins of its celebrated abbey still exist, and are aptly termed by Sir W. Scott, "a solemn, large, and dark red pile." Pop. (1851) 908.

HOLY-STONE, a large stone used for cleaning ship's decks. It receives its name from the unwillingness of sailors to submit to the drudgery of using it.

HOLYWELL, a municipal and parliamentary borough, and market-town of Flintshire, North Wales, 15 miles N.W. of Chester. It is pleasantly situated on an eminence near the left bank of the estuary of the Dee. The streets are irregular but spacious and well paved, while many of the buildings are substantial and elegant, and give the town an air of prosperity and opulence. Until the commencement of the present century the town was inconsiderable, but owing to the extension of its mines, and the successful establishment of several manufactories, it has become the largest in the county. The church, erected in 1769, but retaining some columns of a more ancient structure, is a plain edifice, with a strong embattled tower, dedicated to Gwenfrewi or St Winefrid. Holywell has manufactures of cottons and galloons, besides smelting houses and foundries. In the vicinity are collieries, and valuable mines of lead, copper, and zinc. It has a station on the Chester and Holyhead railway. It takes its name from the celebrated well of St Winefrid, long reckoned one of the seven wonders of Wales. The spring is estimated by Pennant to discharge 21 tons of water in a minute; and its temperature is at all seasons several degrees higher than the mean temperature of the district. The well is covered by a beautiful Gothic building, said to have been erected by Margaret, Countess of Richmond, mother of Henry VII. It is a contributory borough to Flint in returning a member to parliament. Pop. (1851) 5740.

HOLZMINDEN, a town of Brunswick, on the right bank of the Weser, at the foot of the Sollinger Mountains, 56 miles S.W. of Brunswick. It is a place of great manufacturing activity, producing largely iron and steel wares, hosiery, flannel, linen, paper, leather, &c.; and has an active river trade. It has two churches, a synagogue, gymnasium, and public library. Pop. about 4000.

HOME, Henry, Lord Kames, a celebrated Scottish lawyer and writer, was born in Berwickshire in 1696. He received his early education in languages and mathematics from the family tutor. He studied civil law and municipal jurisprudence at the University of Edinburgh. Finding it necessary, in order to become a finished barrister, to pay special attention to the forms and business of courts, he attended the chamber of a writer to the signet. His ability and great application rendered him a successful advocate, in which capacity he began to practise in 1724. In 1752 his genius, in addition to his other qualities, elevated him to the seat of judge of the Court of Session. This high office he held under the title of Lord Kames, with distinguished reputation for thirty years. In 1763 he was made one of the Lords of Justiciary. He died 27th December 1782, at the advanced age of eighty-six.

Lord Kames applied his vigorous intellect to metaphysics and criticism as well as to law, and occupied no small portion of his long life in promoting trade and in the improvement of agriculture. His publications on subjects relating to law form a numerous catalogue. In 1728 he published

Remarkable Decisions of the Court of Session during the previous Twelve Years, in 1 vol. folio. In 1732 appeared his essays on *Jus tertii*, *Beneficium cedendarum Actionum*, &c., 1 vol. 8vo. These essays were received with admiration. In 1741 appeared his *Decisions of the Court of Session* during its whole existence, abridged and arranged like a dictionary, extremely useful to the practical lawyer, 2 vols. folio. In 1747 appeared his *British Antiquities*, relating to law, such as the introduction of the feudal law into Scotland, &c., in 1 vol. 8vo. In 1757 appeared his abridgment of the *Statute Law of Scotland, with Historical Notes*, in 1 vol. 8vo. In 1759 he published *Historical Law Tracts*, in 2 vols. 8vo. In 1760 appeared his *Principles of Equity*, in 1 vol. folio. In 1766 he gave another volume of *Remarkable Decisions of the Court of Session from* 1730 *to* 1752, 1 vol. folio. In 1777 he published *Elucidations respecting the Common and Statute Law of Scotland*, 1 vol. 8vo. In 1780 appeared his *Select Decisions of the Court of Session from* 1752 *to* 1768, in 1 vol. folio. These numerous publications within his proper sphere of law, display amazing activity and industry extended to the very close of his life.

But we have now to follow Lord Kames into another domain; for useful as were his law publications at the time, and even still, his fame does not mainly rest on them. He had corresponded with Butler, Berkeley, and Clarke, at an early period, and possessed a decided inclination for metaphysical studies. In 1751 appeared *Essays on the Principles of Morality and Natural Religion*, in 1 vol. 8vo, from his pen. This work gave some offence, because the doctrine of philosophical necessity, as stated by him, was considered as coming into collision with the interests of religion. He altered some of the obnoxious expressions, but adhered to his doctrine in the main.

He refused to reduce all the springs of human action to one principle, and to undervalue reason to the extent to which incautious theologians are sometimes disposed to do. It is said that a Dissenting professor, mistaking the "necessity" of the philosopher for the "predestination" of Calvin, had the hardihood to recommend the treatise to his students. In 1761 Lord Kames published his *Introduction to the Art of Thinking*, 1 vol. 12mo. In 1762 appeared his *Elements of Criticism*, upon which his fame is chiefly founded. This work quickly took precedence of such as had been in more general use before it. Lord Kames, in this able and original work endeavours to analyze the sublime and beautiful. Whatever comes under the one or the other of these denominations must be considered partly as it is in itself, and partly as to the means which we have of receiving the impression, *i. e.*, our faculties. But not only so, the object is to be considered not simply as to itself, but also as to the circumstances and associations connected with it. He encounters and freely admits the difficulty which occurs in the fact, that a pleasurable emotion should be the result of two things so different as the sublime and beautiful. His analysis of the sublime is more successful than that of the beautiful; the latter he sometimes decides from a merely utilitarian point of view.

In addition to all the foregoing labours, Lord Kames was a zealous promoter of the agricultural and commercial interests of Scotland. He had the chief management of numerous boards of fisheries and manufactures, and was one of the first patrons of the Physical and Literary Society—afterwards the Royal Society of Edinburgh. In 1772 he published a work on agriculture, entitled, *The Gentleman Farmer, being an Attempt to improve Agriculture, by subjecting it to the Test of Rational Principles.* His work, *Sketches of the History of Man*, appeared in the following year, but was less accurate than entertaining. His last work was *Loose Hints upon Education*, 1781, 1 vol. 8vo. In this work, written in his 85th year, he earnestly inculcates the importance of training up youth in virtue and industry. He attended the Court of Session to within a short time of his decease. A few days before he died he addressed each of the judges separately, and took an affectionate farewell. He was of an extremely lively disposition, and warm in his friendships. His abiding sense of an intelligent Providence continually led him to trace out evidences of wisdom in nature. For his life, see *Woodhouselee's Account*, in 2 vols. 4to, 1807.

Home, *John*, the author of the well-known tragedy of *Douglas*, was born in 1722 at Leith, of which place his father was town-clerk. He was educated at the grammar school of his native town, and afterwards at the University of Edinburgh. Admitted into the church in 1745, he was in the following year appointed to succeed Robert Blair, author of *The Grave*, as minister of the parish of Athelstaneford. Here he composed that play which has hitherto kept his name from oblivion; and which, when rejected by Garrick, was acted with splendid success on the Edinburgh stage. It is hard for the strictest purists to discover anything in this tragedy that is not perfectly consistent with the most rigid code of morals. Its appearance on the stage, however, raised a storm in the Church; and one clergyman was suspended from his office for having gone to the theatre to see it played. Home was himself threatened with deposition; and many of his friends were loaded with abuse. By the following Assembly, however, he was treated with greater lenity; and though he resigned his charge on the June following, and retired to England, it was without the stigma of ecclesiastical censure. The drama itself is not altogether that piece of empty and sonorous bombast that it is sometimes alleged to be. Its moral tone and purport are high; its plot, if not wrought out with the highest tragic skill, is at least interesting; and the diction is chaste and polished, sometimes even elegant. Home's subsequent plays of *Agis*, *The Siege of Aquileia*, *The Fatal Discovery*, *Alonzo*, and *Alfred*, did not enjoy even a temporary success; and his only historical work, *The History of the Rebellion in Scotland in* 1745-6, was hardly more fortunate. In 1762, the year in which Samuel Johnson was pensioned, Home was similarly rewarded, and to the same amount (L.300 a-year), through the influence of Lord Bute. For ten years after his retirement from the church, Home lived chiefly in London. In 1767 he returned to Scotland, where he spent the remainder of his days, varying the ordinary routine of his life by annual visits to London. He died at Merchiston, near Edinburgh, in 1808, in his 86th year. The character of his only successful play has been already indicated. It only remains to add that in private life he was one of the most amiable men of his age. Though fond of the society of the great, he courted rather than shunned that of his humble friends, and it was one of his chief duties and pleasures to bring forward and encourage rising talent. Many a youth who afterwards rose to wealth and fame owed his first step in life to the good offices of the author of *Douglas*.

Home, *Sir Everard*, an eminent surgeon, was born about the year 1755. He was of Scottish extraction, and his connection with the Hunters brought him into notice at an early period of life. At one time he was held in high estimation as a surgical practitioner. He was one of the surgeons to St George's Hospital; and this circumstance, added to the publication of various works which attained a considerable share of celebrity, contributed to extend his reputation, the advantages of which he lived nearly half a century to enjoy. In 1813 he was created a baronet, and was also appointed serjeant-surgeon to the king. He died August 31, 1832, in the 77th year of his age. He was the author of *Practical Observations on Stricture; Lectures on Comparative Anatomy;* and of various papers in the *Philosophical Transactions.*

HOMER, the greatest epic poet of Greece, and a name of the highest significance, not with regard to Greece only, but to Europe generally, and to the history of the human race. For in Homer we have to do not merely with a poet of the first class, holding the same place in literature that Aristotle and Newton do in science, but with the oldest records, after the books of Moses, that have exercised a permanent influence on the civilization of the west. It is but reasonable, therefore, that we should give a more full and minute consideration to the Homeric poems, than even the high position of their author on the topmost peak of the Hellenic Parnassus would justify.

The life of Homer did not fall within the strictly historical epoch of Greek literature; nor were there any diligent biographers in his day who made it a business to collect and to make public the notable sayings and doings of men of extraordinary genius. The existing literary testimonies for the facts connected with the life of the poet, do not carry us further back than the age of Pindar (B.C. 500); that is to say, to a period more than three hundred years posterior to the age of the great poet, taken at the latest of the various dates to which it is assigned. What we know of Homer, therefore, we know only through the channel of national tradition, uncertain and vague as that must always be in an age when writing was either unknown or little practised, and criticism of literary documents never dreamt of. We shall not, therefore, be surprised to hear that even the birthplace of their great national poet was unknown to the Greeks, and that the period in which he flourished was a puzzle to their ablest chronologers. We are not, however, to suppose that on this interesting subject we know absolutely nothing. However vague popular traditions may be, and however discrepant in minor details, they will generally be found to contain a nucleus of truth which a practised eye can readily distinguish from the fabulous accretions of idle or impudent imaginations; and if the general substance of such traditions regarding the life of a great poet, is not contradicted, or is rather confirmed, by the internal evidence of his reputed works, a reasonable man may take his stand upon them as confidently as he does upon any other conclusion, resting upon evidence which may reach the highest degree of probability, but can in no case partake of absolute scientific certainty.

The authorship of the *Lives* of Homer, printed in Barnes', and other editions, and in Westermann's collection (Βιογράφοι, Brunswick, 1845), is unknown; but their value as literary documents depends not on what the authors say in their own name, which is utterly worthless, but on the ancient authorities and special popular traditions which they quote. From them we know what was the account given by Aristotle of the birthplace of Homer, what Ephorus said was the local tradition of the people of Cumæ, and what Homeric monuments were shown by the islanders of Ios. A very slight consideration of these ancient testimonies thus analysed will suffice to show the vanity of the claims put forth by various Greek cities as having given birth to Homer. Of these, seven is the number commonly mentioned in a well-known distich (*Aul. Gell.*, iii., 11); but the reader who chooses to turn up Suidas will find at least half a dozen more; and to increase learning in this matter will only be to increase scepticism, unless a man carries with him the sound maxim of the lawyers, *ponderanda sunt testimonia non numeranda.* The claims of Athens, for instance, rest, according to a distinct testimony (*Lives* δ and ϵ in Westermann), on the mere fact that the Ionians of Smyrna were a colony from Attica, and that if Homer was a Smyrniote, he might reasonably be called an Athenian, just as a person born in Sydney may say he is a Londoner, because his father or his grandfather, or his great-grandfather was so. In a similar loose fashion the claims of Salamis in Cyprus, are found to be explained by the fact that Stasinus, one of the poets of the *Epic Cycle,* was a native of that island, and that the epic poem called Cypria, written by him, was by some attributed to Homer, from whom Stasinus is said to have received it as a marriage gift with the daughter of the great poet (Ælian, V. H. ix., 15). Colophon, in a similar way, claimed to have produced the poet of the *Iliad,* because of a famous humorous poem called the Margites, of which Homer was generally supposed to be the author (Welcker, *Epic Cycle,* i., 184). But the same critical inspection which enables us to expose the flimsy pretensions of these places, reveals the remarkable fact that those other cities which have most to say for themselves as being the native country of Homer, unite, by the peculiar form of their traditions, in giving to Smyrna at least some share in his birth,—a plain admission that at the time when these traditions were framed, the claims of Smyrna were considered so strong that they could not possibly be ignored. Thus the most detailed and best known *Life,* that attributed to Herodotus, which was for a long time received as authentic, deduces the parentage of Homer from Magnesia, in Thessaly; thence Melanopus is said to have crossed the Ægean, and settled in Cumæ, the principal city of the Æolians, in Asia Minor; here he married a lady of Cumæ, by whom he had a daughter called Critheis; and this maiden having, unknown to her guardians, formed a connection with some unknown individual of the male sex, was, to avoid exposure, sent to Smyrna, where, on the banks of the River Meles, she brought forth Homer, thence called Melesigenes. We have already said that such local traditions are not history; but when we find another of the seven cities, namely, Ios, framing a local legend, which, while differing from that of Cumæ in every other point, agrees with it in bringing the immortal minstrel to the banks of the Meles to be born, we must be altogether blind to the spirit in which local legends are composed, if we do not see here the strongest proof that the real country of Homer was that which is distinctly allowed in the legends of those very cities which are most interested in denying its claims. We say, therefore, that according to all human probability, Homer was born at Smyrna; and when we say, with equal probability, that he died at Ios,—one of the Cyclades in the Archipelago,—for on this point the various accounts also agree,—we have stated all that can be said to be known with regard to the father of epic poetry in Greece. The other events of his life, as given in the longer biographies, are fictions invented, many of them, with the plain purpose of giving a historical existence to certain of the characters mentioned in the *Iliad* and *Odyssey;* or they are mere blunders of which the source is innocent and obvious. That, like all minstrels, Homer was given to wander about from place to place in the exercise of his vocation is probable enough without any voucher, and appears quite certain from the extensive and accurate geographical information displayed in his works; but the details of his travels would be curiously retained in no man's memory; and what we have for them bears all the marks of a vulgar forgery. The much-bespoken circumstance of his being blind, noticed in all the ancient *Lives,* if implying a mere superinduced misfortune, and not a congenital defect, might, as a matter of popular tradition, be probable enough, were the origin of the story not too plain in the double fact that a blind poet is introduced in the *Odyssey* (viii. 64), and in the famous hymn to Apollo, which Thucydides (iii. 104) and other ancients accepted as the productions of the genuine Homer. This hymn, indeed, must be regarded as the main authority of those who claimed Homer as a Sciote: for the lines run expressly—

Τυφλὸς ἀνὴρ, ὀικεῖ δε Χίῳ ἔνι παιπαλοέσσῃ.
The blind old man who dwells in Chios' rocky isle;

and there is certainly no evidence so strong in favour of Smyrna, provided only it could be proved—what no scholar now dreams—that these lines were really so said and sung by the veritable singer of the *Iliad* and *Odyssey*. But after this line is rejected, there remains no ground for the claims of Chios, save that weak one expressly mentioned by Strabo (xiv., p. 645), that in this city there flourished the famous guild or brotherhood of minstrels (of whom more anon), known by the name of the Homeridæ; a fact of no more power, when critically examined, to prove that Homer himself was a Chiote, than the fact of Calvinistic theology being very dominant in Scotland would prove that the author of the doctrine was born in Edinburgh.

The age of Homer is a matter about which less that is satisfactory can be stated, than with regard to his country. That if not a Smyrniote he was at least a native of that part of Asia Minor, is proved not merely by the traditional evidence just adduced, but by the internal evidence of the poems themselves—by their rich tone, colour, and style, and also by many well-known facts relative to the early rise and growth of poetic literature among the Greeks. But chronology is, in the nature of the thing, a matter with which popular tradition has nothing to do: and the internal evidence of the poems themselves on this head, though strong enough, perhaps, to exclude certain extreme suppositions, affords a pretty wide range to a merely conjectural chronology. Herodotus, in a well-known passage (ii., 53), places Homer about four hundred years older than himself; that is, in the year 850 B.C., or thereabout; Aristotle, in the account given by him of the legend of Ios, makes the birth of Homer contemporary with the great Ionic migration (1044 B.C.); while Dionysius of Samos, the cyclographer, threw him back as far as the Trojan War, which he describes. To determine exactly between these contending dates, and at least a dozen more given in a very full scheme by Lauer (*Homerische Poesie*, p. 124), is of course hopeless; but the circumstances of the case warrant us in refusing to allow any date for Homer, so early as that assumed by the cyclographer, or later than that given by Herodotus. For such an extensive collection of myths as that connected with the Trojan War requires time to grow; and Homer manifestly talks of the heroes of the *Iliad* as belonging to some age not altogether identical with his own. The mingled elements, also, of Ionian and Æolic Hellenism, which appear in the Homeric poems, did not exist in Asia Minor at the early date supposed by Dionysius, or those who come near to him. As little, on the other hand, can we go beyond Herodotus, in bringing Homer nearer to the date of the Olympiads than the year 850, for the very uncertainty in which the wisest Greeks were as to the age of the poet, proves that he lived at a period considerably more ancient than the first year (776 B.C.) of their recognised national chronology.

Perhaps some reader may have been content that we should allude to these disputed points in a manner even more perfunctory than we have done; but in these days of rampant historical scepticism, imported wholesale from Germany, it is absolutely necessary to make some attempt to mark distinctly where the cloud-architecture of mere imagination ends, and the mainland of actual tradition, hazy and yet indubitable, commences. In reference to these sceptical views of the Germans, we cannot avoid noticing here that some of them have even gone so far as to deny the existence of such a man as Homer altogether; and, what is of more consequence to us, the language, which some of the more wild of that sect are still in the habit of using, has been adopted by some of our own scholars whose name is sufficient to make even their incidental errors dangerous. Mr Grote, for instance, uses the following language:—"The name of Homer—*for I disallow his historical personality*—means the *Iliad* and the *Odyssey*, and nothing else;" and again, "Homer is no individual man, but the divine or heroic father of the Gentile Homerids" (vol. ii., p. 179); that is to say, while the whole of the Greek nation believed they had once had a great epic poet to whose extraordinary genius, as to a natural and adequate cause, they attributed their two great epic poems (just as the ordered world finds the best explanation of its existence in a God); we, the learned of modern times, are bound to doubt whether that poet had any existence, and to treat these poems as if they were not productions of a great poetic genius at all, but the creation of some half dozen or a score of second-rate rhymers, whose names no person ever cared to know, but who were cunning enough to raise themselves into a fictitious historical consequence by the creation of a symbolical head of their corporation called Homer, whom the silly world has, for nearly 3000 years, been willing to take for a substantial reality! Now, it ought at once to be granted to Mr Grote, and those Germans whose nebulous notions he has in this matter imported, that there was a tendency in the earliest times of the Greeks, as perhaps of all highly imaginative nations, to represent in the historical form certain favourite ideas and theories, theological and ethnological; which allegorical or mythical narratives, a modern reader of a prosaic temper may be apt to mistake for realities. Of the religious myth in particular, the historic was the generally accredited form, to such an extent that the original physico-theological ideas which these narratives were invented to convey, are now but dimly discernible behind the motley company of human incarnations by which they are impersonated. Nay, more, it may even be true in some cases, according to a favourite notion of the Germans (Uschold and others), that the religious symbols of one century became the anthropomorphic gods of another, and dwindled down to the merely human heroes of a third. Further, it is not to be denied that beyond the sphere of religion the practice seems to have prevailed among the Greeks to a certain extent of inventing names of characters, apparently historical, to symbolize the origin and the connection of certain notable races of men. Thus Hellen, in whose personality the most critical of ancients believed (see Thucyd. I. 3), is taken by almost all modern writers, even by Clinton, for a mere name invented as a symbol of the common nationality of the people whom he represented. But even with regard to national genealogies, we are in nowise entitled to assume that because they are peculiarly liable to forgery, therefore no national genealogy is in any case to be accepted as true. Much less are we to make a general rule of evaporating all the most deeply-rooted local traditions of a country into mere misty imaginations and unsubstantial symbols, and to assume that the "manufacture of fictitious personalities" (Grote), was the only or the main function of the popular intellect of any people, at any stage of their civilization. Man is a real creature, and he deals with realities; and of all realities, those which he is least disposed to lose hold of are the great men whose energy fathers any extraordinary product of the national life, and whose name marks any great national epoch. In conformity with this real tendency of human nature we find that in all popular poetry the actions of famous men—the national heroes—form a much more prominent element than symbolized religious or physical philosophy (see some admirable remarks in Lauer, p. 131–174); and the periods of intellectual and political advancement marked by such names as Homer and Theseus are precisely those in which a great reality would be more powerful to seize the minds of men than the most significant symbol. Extraordinary and even miraculous stories in the life of a historical personage ought not in the very least to shake our credit in his fundamental reality; for it is precisely because his reality was so striking and so overpowering that these miraculous stories were invented, and naturally found credit. The Israelites carried back the genealogy of their nation to the son of Isaac, from whom they sprung. Had the books of Moses, with all their circumstantial details and life-like reality never been written, a German philologer might have said that Jacob was merely a symbol. In the same way the Athenians ascribed certain great political changes in their country to the son of Ægeus, of whom various wonderful and superhuman stories are told; but these stories no more justify us in throwing him into the limbo of symbols, than the ridiculous lies about Abraham and the other patriarchs, current in the Koran and other Eastern books, would entitle us to disallow the historical reality of the father of the faithful. In the same way—though there are some things of a plainly mythical nature in the traditional legends of Homer—to conclude from these that Homer himself is a myth, is to argue with the precipitation of a whim-intoxicated German, not with the deliberation of a sober-minded and judicious Englishman. Indeed, it is only doing the Germans justice to state that the "disallowance of the personality of Homer," to use Mr Grote's phrase, is by no means so common among them now as in the first fever of intemperate Wolfian enthusiasm it might have been without offence. William Müller, the most popular champion of Wolfian ideas, says distinctly, in his *Vorschule* (p. 51), that "we are not called upon to question the personal existence of Homer;" and Professor Welcker (to whose learned labours all students of Homer are so much indebted), Nitsch, C. O. Müller, Dr Ihne (in Smith's *Dictionary*), Baümlein, Lauer, and others who have written recently on the subject, show a moderation of temper, and a soundness of historical judgment, very far removed from what we are accustomed to designate as "German extravagance." It is becoming evident to a thoughtful observer that even among that most speculative, sceptical, and, intellectually speaking, most anarchical nation of Europe, the conflict of extreme views is beginning to produce its natural result in the recognition of the great human realities which lie at the bottom of the strong though unpurified historical convictions of the masses.

So much for the poet. The next question that presents itself in connection with the name of Homer is that of the authenticity of the works which go under his name. What security have we that the poems we now read with such delight and instruction are the identical works which Aristotle analysed, which Plato denounced, which Thucydides and Strabo quoted as the best authority for some of the earliest and most important facts in Greek history and topography? What guarantee, further, that the works which the great writers of the classic age of Greece, received as genuine works of the great Ionian bard, actually were so; and how far they might not have been made subject to various interpolations and mutilations in the three or four centuries that elapsed between the heroic age, when they were composed, and the historic age, when we find them made the subject of literary study and criticism? The importance of these questions will appear the more strongly when we bear in mind that the celebrity of Homer naturally led to the national practice of stamping with his name many poetical works of a popular character, in which the stern tests applied by a severe criticism refuse to find any marks of so illustrious a paternity. Prominent among these are the Homeric hymns, treated as authentic by Thucydides, and published as undoubted works of the great bard in the *Editio Princeps* and other notable editions by modern scholars. Of the same kind are the *Cypria* already mentioned, of the contents of which a short account is given by Proclus the grammarian. To Homer also was very generally attributed by the ancients the Colopherian poem called *Margites*; and the *Battle of the Frogs and Mice* is an example of one of the many *πάιγνια*, or humorous popular pieces, with the composition of which the singer of the wrath of Achilles is supposed to have amused his mighty mind in his hours of relaxation. With regard to all these it may be sufficient to state that the ancients themselves were very far from exhibiting a serious agreement as to their authorship; and their being attributed to Homer must be viewed as rather a favourite floating popular belief than a strong national conviction. Such being their character, it could not be expected that they should stand muster before the scrutinizing glance of modern criticism, and the sceptical analysis of the Germans. In talking of the Homeric poems we must therefore remove these minor works altogether from our view; but the fact of their having been for a long period so generally received as genuine works of the poet, leads us to treat with the greater consideration the caution of those who demand the severest proof for the real authorship of the *Iliad* and the *Odyssey*. Now, with regard to these two great works, there is, in the first place, not the slightest reason to doubt that we possess and use them, so far as the contents and the text are concerned, exactly as they were possessed and used by the Greeks of the classic ages; and with regard to their authorship the faith which we have that these identical works were the genuine works of the great Ionian epopœist was the general faith of the whole ancient world, both Greek and Roman; and in the case of the *Iliad* at least (for there were some difficulties started by a few curious inquirers with regard to the *Odyssey*), a faith for centuries unshaken by a single breath of contradiction. That the *Iliad*, which we now read, is substantially the *Iliad* of Pindar and of Plato, can be proved to the satisfaction of any sane man, exactly in the same way that the Christian Scriptures read now in the Christian churches are proved to be substantially the same as those expounded by the earliest bishops, and sanctioned by the most authoritative councils of the Church. To the Greeks Homer was in fact a bible, and guarded with all the care and all the piety that belongs to such a book; a fact which at once explains the extravagant, and, to our feeling, illiberal zeal with which Plato denounces it in his ideal polity, and at the same time puts into our hands a guarantee of the surest and most sacred kind for the general authenticity of the poems as we now read them. No person who is even superficially read in the Greek classics can fail to have observed how constantly all writers of note, from the severe and stern Aristotle to the light and sportive Lucian, refer to Homer as to a writer of whom a universal knowledge might be presupposed in all their readers, and to whom a universal respect was paid. The consequence of this frequent reference is, that there is no writer of antiquity of whom we are more sure that we possess his genuine words as current in the mouths of the ancients, than we are with regard to the author of the *Iliad* and the *Odyssey*. But more than this. In the time of the Ptolemies, and when the productive power of Greek literature had begun to faint and die away, there was a special band of learned critics and commentators, who made it their business to collate the various recensions of the Homeric epics, and to transmit their text to us with as much conscientious fidelity as was possible. Prominent among these were Aristarchus and Zenodotus, of whom the first has transmitted his name to modern times as a popular appellative for the literary man who exercises the higher sort of documental criticism as a vocation; and not only do we know that such men existed, and exercised their philologic care on the great national treasure of the Homeric text, but we have in the Venetian scholia, first published from the St Mark's library by Villoison (1788), a series of notices of their method of critical procedure, and a list of their asterisks and obelisks, sufficient to dispel all doubts as to the unadulterated transmission of the *Iliad* and *Odyssey*, at least from the period when letters began to be a study and an occupation in Greece. But when did this period begin? and what have we to say for the nature of the guarantees of authenticity, whatever they were, that existed before this period? These are the really serious questions, the answers to which have raised difficulties that have made wise men pause and foolish men stumble, not without observation. On all hands it is allowed that Pisistratus, the well-known Athenian tyrant (B.C. 560), was the first, so far at least as Athens is concerned, to collect together the various books or rhapsodies of the Homeric epics, which were generally sung or recited separately, and to arrange and publish them—to use a modern phrase—in the form in which they now exist. Pisistratus, therefore, or rather his literary coadjutors, among whom Onomacritus is prominently named, must be regarded as our first historical guarantee for the text of the *Iliad* and *Odyssey* as we now possess it; but the details of his literary labours are unfortunately not in the least known to us; so from this point backward we are left to conjecture, to historical probabilities and internal evidence, and to the hundred and one small sceptical doubts and sceptical solutions of those doubts, which will never cease to exercise the wits of those who are born to torment themselves in this way. The question whether the *Iliad* as arranged by Pisistratus was, both in point of matter and arrangement, exactly the same as the *Iliad*, of which Homer was then the reputed author, is a question that in the nature of the case admits of no perfectly satisfactory answer. *Absolutely* the same of course in the nature of human things it cannot be; for even the Christian Scriptures, guarded as they have been by the double sanction of individual and corporate authority, have not been transmitted through eighteen centuries of literary record without being made subject to several very notable interpolations: nor can it even be said that any man at the present day can feel the same degree of certainty with regard to the text of Homer that he does with regard to that of Milton, Tasso, Dante, or even Virgil. Why? Not only because of the greater lapse of time; for in a question of documentary criticism this is often a point of comparatively small moment; but because of the different conditions under which these works were composed, and the different medium through which, in their earliest stage, they were transmitted. We read of no Pisistratus that first collected the scattered books of the *Æneid;* the very MS. which Dante gloried in, or something as good, is no doubt lying in the Grand Duke's library in Florence at the present hour. In the case of these poets people may be vexed with various readings and doubtful lines—such questions as curious editors will raise even with regard to modern Scotts and Byrons; but there is no talk about cutting out whole books, and the strange process with which learned Germans are so familiar, of restoring a great poem to its integrity by depriving it of some of its most beautiful parts. Let us endeavour then to fix a steady eye on the real state of the Homeric text at the time when it was collected by Pisistratus. What reason have we to suppose that it was then to any considerable extent interpolated, or changed in any way from its original condition as it came from the mouth of Homer? The answer to this question depends upon another. Who were the conservators of that trust previous to the time of Pisistratus; and what safeguards were they provided with against those invasions of spurious matter to which all works of extensive circulation, and general popularity, are especially subject? The conservators of the trust are, in the first place, the national ἀοιδοὶ, minstrels or bards, who, like Homer himself, made a profession of singing songs and epic poems for the amusement of the people; and, when these had begun to wane, they were succeeded by the rhapsodists or popular reciters, who performed the same functions, but with less original genius and less social dignity in an age when historians, and orators, and philosophers, and rhetoricians, had usurped many of the functions that had originally been exercised by the ἀοιδὸς. Now it is of immense importance in the criticism of Homer to ascertain clearly if possible what was the moral position of the original minstrels' profession with regard to the great poet: for on this depends the likelihood of their either loosely interpolating or conscientiously respecting the integrity of his works. That they cannot have felt the same religious sort of respect for him that arose in the Greeks of a later age, seems pretty evident; they were minstrels by trade as well as he, and could only look upon him in the exercise of their profession as *primus inter pares.* Nevertheless, they did respect him very much; of which we have ample evidence in the existence of the famous guild or institution of poets in Chios, known by the name of the *Homeridæ*, or sons of Homer, concerning whom we have the most distinct testimony in Harpocration. Whether any of the actual descendants of the poet formed the original nucleus of this fraternity we cannot tell; but its existence under that designation is ample proof of the extraordinary respect in which Homer continued to be held in the parts of Asia nearest to his birthplace, and affords a sufficient practical guarantee that the professional minstrels who were incorporated under this name would not, from mere rash conceit, be inclined to tamper with the tradition of the Smyrnæan muse of which they were the select depositaries. On the other hand, it must not be forgotten that a poem like the *Iliad*, made not to be read as a continuous book, but to be sung in separate parts for the public amusement, was peculiarly liable to have such additions made to it or variations as the occasion might require. Of this our own ballads (see Chambers' *Songs and Ballads of Scotland*, p. 106, note) supply everywhere abundant proof, the existing version of which is often pieced together from a variety of different texts, presenting all sorts of deficiencies and redundancies. That something of this kind should not have taken place with regard to the Homeric poems in general circulation through the scattered tribes of the Greeks, would have been positively miraculous; and we must suppose that the principal business of Pisistratus, in collecting these poems, was not, as some have strangely supposed, to create an order which never existed, but to fix an order which was in danger of being lost. Whether in doing so he had the advantage of any complete correct text derived from the Homeridæ of Chios, with which to compose and correct the scattered rhapsodies in popular currency, we cannot say; but it is not at all unlikely;—at any rate he would have little difficulty in restoring the original arrangement of the books, partly because that order in the generality of cases shines out manifestly from the inherent character of the plot, and the progress of the story, partly because there could not fail to exist among the more literate and accomplished of the rhapsodists some one who could recite by memory not merely single books, but the whole concatenation of books, as the Homeridæ of Chios had received them from their great father. Most assuredly, as has been insisted on both by Baümlein and Grote, he never could have set himself seriously to make extensive modern interpolations in poems, the contents of which were well known over the whole of Greece, and had in Athens been made the subject of a special public regulation by their great lawgiver, Solon. (See *Diog. Laert.* in Solon 9.)

In the view here given of the respective functions of the Homeridæ, and of Pisistratus, in the transmission of the Homeric poems, we have said nothing about the famous question, *whether the art of writing was known in Homer's time?* because a little reflection will show that this question has really very little bearing on the genuineness of the poems as we now possess them, and besides is a question that does not admit of a satisfactory answer. At the first blush, indeed, when a modern who is the slave of pen and ink, hears it stated that in all likelihood the great bard of the *Iliad* could neither read nor write, he is apt to feel very much as if the whole foundation for his critical faith in the poet was removed from beneath his feet, and there was no longer any ground for him to stand on. How many an eloquent modern speaker might be struck dumb if pen, ink, and paper were suddenly removed from the category of things that be! But they managed these matters differently on Parnassus and Helicon in the days when Memory was the mother of the Muses, and the Muses could sing sweetly without help from a goose quill. We have the most distinct testimony of Julius Cæsar (B. C. vi. 14), to the effect "that the pupils of the Druids learn by heart a great number of verses; and some continue twenty years in a course of instruction. *Nor do they think it right to commit their doctrines to writing, though in other matters they use the Greek alphabet. This they appear to me to do for two reasons; first, that they may not make their religious mysteries too common and profane by general publication, and again, that they may not weaken the power of memory in their scholars by teaching them to trust to written notes; for nothing is more common than that the abundance of literary helps teaches persons to remit their exertions in committing their knowledge to memory.*" This remarkable passage reveals to us in the most striking manner the real secret of the transmission of the Homeric poems without the help of written manuscripts; the memory of the minstrels was not more uncertain, but more true and trustworthy for this very reason, that they were not accustomed to depend for the faithful recollection of the poems which they recited, upon a leaf of papyrus or a library itself. In estimating the memorial powers of these men we must never forget not only that they exercised their art under intellectual conditions exactly the reverse of those which now exist, but also that they had no other business or interests by which to distract their attention, and so could perform certain feats with ease, that bear the same relation to our common exercises of memory, that tumbling and rope-dancing do to common walking. It is always in our power, by exclusive and persevering exercise of a favourite faculty in a favourite sphere, to perform apparent prodigies. We shall therefore readily disabuse ourselves of the superficial modern notion that written memoranda are necessary to the faithfulness of versified tradition; the "wonder," as it has been called by Grote, of the "preservation" of such long poems from such early ages will become part of the common intellectual drill of an age eloquent without paper, and poetical without ink; and the question will only remain, as a matter of legitimate curiosity with regard to the *Iliad* and *Odyssey*, whether their author was acquainted with those useful arts of literary conservation, the knowledge of which is in our days justly accounted a necessary element in the lowest stages of popular education. Now with regard to the use of letters in Greece, the general voice of Hellenic antiquity pointed to Cadmus as having imported these cunning symbols from Phœnicia at a period far antecedent to the age of Homer, or even the supposed date of the Trojan War; and this tradition is consistent not only with the philological analysis of their letters of the alphabet, but with the then general state of the civilization, and the admitted intercourse between Asia and the West as having taken place in various forms at a very early period of the history of the world. There is every probability, therefore, in favour of the belief that letters, in some shape or other, were known in Greece, at whatever date, between the Trojan War and the year 850, which may be assumed as most convenient for the age of Homer. But from this probable belief with regard to the epoch of the knowledge of letters in Greece, the distance to a reasonable conviction, with regard to the practice of Homer himself in composing and preserving his poems, is very great, and not lightly to be overlooked. That letters, when first introduced, were used only in great public matters, and for inscriptions in wood, stone, lead, and other heavy materials, not for writing a long concatenation of poetic rhapsodies, is conformable to the nature of the thing, and to every testimony that we have on the subject. According to the usual slow progress of human affairs, three centuries at least may well have been required to transfer letters from the rare service of temple-porticoes and monumental pillars, to the common use of literary conservation; so that, even assuming the use of letters for public purposes in the days of Homer, the probability may be considered very small that they were actually used by the poet or his immediate successors for any merely literary purpose. This probability becomes even less, when we consider that there is not a single allusion in the whole forty-eight books of the two poems to writing or books as a part of the civilization which they describe (the *σήματα λυγρὰ*, in *Iliad*, vi. 168, being ambiguous); and though this in itself were no conclusive argument, as any poet who uses pen and ink is not even in these days obliged to make his heroes do so, yet taken in connection with the general character of the poems, and the circumstances of the time, as ascertained by historical analogy, it is in nowise to be looked on as an altogether indifferent circumstance.

So far we have confined our remarks to the external aids and authorities, by means of which the poet and his works are in the first place commended to our attention. It now remains from this general basis of outward historical probabilities and presumptions, to direct our inquiry into the character and genius of the poems themselves, and from this investigation either to transmute our probabilities into certainties, or throw them aside as unsupported, or contradicted by a higher, and the highest sort of evidence. For no mere array of authorities, however venerable, can in the long run support an incoherent tradition that carries its own contradiction in its face. This eternal superiority of immanent and inherent, to merely accredited evidence, has, since Bentley's famous dissection of the epistles of Phalaris, banished from the shelves of authentic classical tradition, many a hoary tome that had long held an honoured place there, along with the most venerated worthies of the Greek and Roman pantheon. How stands the case with regard to the *Iliad* and *Odyssey?* Are these works what they have for nearly three thousand years been reputed to be—the great poems of a great old Ionian poet—or do they bear the trick of forgery on their face, and show the patch-work of a bungling fabricator on the phylacteries of their outer garment?

The severe ordeal which the Homeric poems, in the way of internal analysis, have undergone, takes its rise in modern times from the publication of a famous edition, by F. A. Wolf, a German professor of extraordinary talent, in the year 1795. This scholar, partly following the bent of his own genius, partly no doubt carried along by the general revolutionary tendencies of the age, did, in the Prolegomena prefixed to his edition, set forth an extremely sceptical doctrine with regard to Homer and his poetry, with such rare learning, vigour, and taste, that it was impossible for German minds to resist him; and though the whole tendency and tone of English scholarship runs in a directly contrary direction,[1] as the great work of Clinton sufficiently testifies, it cannot be denied that beyond the pale of mere Oxonians the Wolfian views have exercised no small influence in forming the critical opinions of some of the best educated minds in England. The critical spirit of the age, the sceptical researches of Niebuhr with regard to Roman history, and the increasing action of German scholarship on the learning of this country, have all tended to produce this result. The theory of Wolf, founded not merely on a minute critical analysis of the poems, but, as he imagined also, on satisfactory external evidence, was to the effect, that whether a great poet called Homer ever existed or not, the two great poems generally attributed to him are no homogeneous works created by the plastic power of a presiding genius, but mere aggregates of various origin, gathered together from the great floating element of popular poetry in Greece, and cunningly licked into shape by certain expert literary artizans in the days of Pisistratus. Now, with regard to the external evidence on which this paradox is founded, it seems at this hour generally agreed, even among the Germans, that the authorities relied on by Wolf do in no wise support his extreme conclusion—do not in fact go beyond the historical statement of the matter which we have just made, a statement perfectly consistent both with the personal existence of one great poet, and the organizing action of his presiding spirit on the two great poems that go by his name. The advocates of the Wolfian theory, therefore, are now driven to confine themselves to a series of arguments drawn from the minute critical examination of the text of the poems, by means of which they think they have evolved such an imposing array of inconsistencies, as is utterly incompatible with the belief in the presiding control of one great mind. Among those who have distinguished themselves in this field of what we may call Homeric histology, is Carl Lachmann, lately deceased, a Berlin professor of great erudition and subtilty, as attested by well-known works in various departments of philological investigation. It behoves us, therefore, to inquire, on what presumptions and on what principles the analytic criticism of this school is founded; and when we have shown that these presumptions require to be inverted, and that these principles are either altogether false or altogether misapplied, we may spare our readers the trouble of a minute and curious refutation of the individual objections. Those who wish to pursue the question into its details may consult the little tract of Lachmann (*Betrachtungen über Homer's Ilias*, Berlin, 1847), or the English work of Colonel Mure (*A Critical History of the Language and Literature of Ancient Greece*, 2d edition, London 1854, vols. i. and ii.)—a book replete with the best German learning, and, what is of greater consequence, animated throughout with a spirit of good sense, and a fine poetical appreciation, which very few Germans can boast of.

---

[1] It is remarkable that the germs of the Wolfian theory travelled from this country over to Germany; and Wolf, in his *Prolegomena*, honestly recognizes Wood and Bentley as valuable pioneers of the doctrine which he so eloquently enforces. Bentley's well known utterance with regard to Homer is found in his *Remarks on a late Discourse on Freethinking*, by Phileleutherus Lipsiensis (*Works* by Dyce, iii., 304). "To prove Homer's universal knowledge, our author says, '*he designed his poem for eternity to please and instruct mankind;*' but take my word for it, poor Homer, in those circumstances and early times, had never such aspiring thoughts. *He wrote a sequel of songs and rhapsodies to be sung by himself for small earnings and good cheer, at festivals and other days of merriment;* the *Iliad* he made for the men, and the *Odyssey* for the other sex;" from which passage, thrown out incidentally, however, be it remembered, and not deliberately

In an investigation of this kind the presumptions with which a man starts, though not always distinctly set forth, are of the utmost consequence in determining his procedure. The false historical presumptions from which Wolf proceeded, naturally led him to seek for flaws in the texture of the Homeric poems; and it is manifest that even Mr Grote, who justly considers the extreme Wolfian theory as quite untenable, in propounding his wild scheme of resolving the *Iliad* into two distinct parts, has been influenced, partly by his desire to mitigate what he calls "the wonder" of the creation, and the preservation of two such long continuous poems, bearing the stamp of one mind, in an age when writing was altogether unknown. That there are no external historical presumptions of this kind we have already attempted to show; a presumption of a different kind we shall now state. It is not to be presumed that Homer would be anxiously accurate about the mere articulation or joint-work of his epic poems, for several reasons. *First*, because he was a poet, and aimed, as all true poets do, mainly at producing an effect on the feelings and imaginations of his hearers, not on their mere cognitive capacity. Small mistakes in incidental matters taken cognizance of by the curious understanding only, might, without offence, be committed by a great singer of poetry, as they would certainly not be observed by a healthy-minded hearer; and that mistakes of this kind actually have been made, and are even now daily made by poets and novelists of the highest order, has been shown by Colonel Mure in the most effective manner. *Second*, because he was a popular poet, a wandering minstrel with a lyre in his hand, as he is truly represented in all the old biographies, and not a learned Southey sitting in a library, with books, and desk, and pen and ink, printers' proof sheets, publishers' quarterly reviews, and every sort of literary apparatus of the newest and most approved description. In judging of the *Iliad* as a whole, we must never forget, though it seems to be very generally forgotten, that it was not, could not be, Homer's immediate object to compose a great whole, for the plain and simple reason that he had comparatively few opportunities of using such a whole. His art, therefore, was to concatenate a series of parts, which, while they might be used with effect on a few great festive occasions as a whole, were meant to produce their general and most appreciable effect, in the shape of parts either absolutely complete in themselves, or admitting of being easily supplemented by the indwelling traditional lore, which the poet could legitimately presuppose in the minds of his hearers. Something analagous to this we have in the great historical plays of Shakspeare, consisting of several parts, in any of which if there happened to be some small inconsistencies with the other parts, none but a curious person making a business of criticism would ever notice it, as the parts, though connected in conception, are so constructed as to give the impression of completeness, when they are represented as separate wholes. If this point be duly considered, and there is nothing more certain or more duly attested in the history of these poems, the weakness of a great number of the objections made by Lachmann and Grote to the concatenation of the *Iliad* will instantly appear. The tenth book, for instance—that in which the midnight expedition of Diomedes and Ulysses is described,—has, it is said, no necessary connection with the parts of the poem that precede or follow, and might be cut out without injury. Of course; because it was the object of the poet so to string together a number of little wholes, originally independent, that they might still remain little wholes, and yet become parts of a great whole—an exquisite trick of art plainly, and which, as the whole history of popular poetry teaches, it required precisely a mighty genius like Homer to perform. And this brings us to the third presumption, with which we must start in judging of the alleged inconsistencies of the *Iliad*. We must bear in mind that Homer did not make his materials, but received them; the little wholes which he had to recast and organize into a great whole, already existed in the minds and in the mouths of the people whom he addressed, just as the Romaic ballads that arose out of the war of independence in 1821–7, exist in the minds and mouths of the Hellenes of the present day, waiting for some second Homer, it may be, to fuse them into a great epos of Messolonghi, when the day may

---

measured in every word, one thing seems plain, that by using the word "Sequel," the great critic gives us plainly to understand that he held there was an essential unity of plan going through both works, which puts him plainly out of the roll of thorough-going Wolfians, and advocates of what Nitsch calls the "Klein-lieder-theorie." Among other notable anticipators of Wolf's theory, the case of the Neapolitan philosopher Vico has often been mentioned. See *Scienza nuova libro terzo; della discoverta del vero Omero,* first published in the year 1725, and repeatedly reprinted.

at length have come for that reconstruction of that Byzantine empire which the late Czar of Russia said he would on no account tolerate. In the same way, an epic poem of Caledonian loyalty, were the times favourable, might be made out of the materials contained in the Scottish jacobite songs; and a grander epos still, called "The Fall of Napoleon," might be constructed containing many finely dramatic materials from the war songs composed by Körner and others in the great German rising of 1813. Now, if the rich materials of popular traditionary song, out of which Homer constructed the *Iliad* (and no person who knows anything about such matters will think it more probable that he made it out of nothing), contained, as they could not but contain, certain elements that would be incongruous, when the different parts were worked up into a new whole; and if Homer did not care—as the practice of his art did not require him to be particularly curious—whether every line or phrase that marked the original independence of these parts, was nicely obliterated, it is manifest that the small flaws in the concatenation which may here and there be visible to the curious eye, prove, not, as Lachmann imagines, that one poet did not organize the whole, but that Homer gave himself no concern to disguise the fact, that the several parts of his poem, both in the popular tradition and in the actual practice of his art, had a complete and independent existence apart from the magnificent whole into which his genius had organized them.

These considerations will enable the student of Homer to make short work, not only with the hypercritical captiousness and the peeping anatomy of Lachmann's *Betrachtungen*, but also with the more large and philosophical analysis of Mr Grote. We must not start in our inquiry into the unity of the *Iliad*, with the strong inclination to magnify the importance of small inconsistencies, but with the most charitable desire possible to overlook them. This poet, as compared with Virgil, Dante, or Milton, demands the special indulgence of the critic; and yet it does rather seem that from Wolf down to Grote, the whole army of objectors are keenly set upon being particularly severe, in many cases positively ill-natured, and, from a poetic point of view, as Colonel Mure has triumphantly shown, positively unjust. For not only do they pay no regard to those kindly considerations which we have stated, arising out of the peculiar position of the poet, and the nature of his materials, but with a perverse ingenuity pardonable scarcely in Germans, they insist on judging poetry by rules applicable only to works composed with a strictly practical, or a purely scientific view. If an experienced soldier like Napoleon could criticise with such a cutting eloquence the description of the taking of Troy by the polished and learned Virgil, which yet speaks admirably to the imagination—(see *Classical Museum*, vol. i., p. 205),—how strange and how unreasonable that a gentleman of Mr Grote's discernment should urge as a strong proof against the authenticity of the seventh book of the *Iliad*, the circumstance that it represents a ditch or dyke, as having been made in the ninth year of the war, which, according to all principles of military tactics, should have been made, as Thucydides (I. 11.) seems to have taken the liberty of supposing it was made, in the first year! The answer to all such very scientific cavils is this, that Homer was neither a soldier nor a critic, but a poet; and that when composing the seventh book of the *Iliad*, he had before his mind's eye not a future Vegetius or a Grote, but only the wrath of Achilles, and the place which that occupied in the popular traditions of Æolia. If critical spectacles were not used when popular poems were composed, their correct appreciation can allow no place to scientific microscopes. Many things may be discovered by scientific eyes,—wonders in the white rock, and wonders in the blue cheese,—but the character and effect of popular poetry does not come within the laws of that particular kind of vision. Even Mr Grote, who has so ably exposed the absurdity of the Wolfian "small song theory" (*Klein-lieder-theorie*), which resolves the *Iliad* into an aggregate of separate ballads, implying no common authorship on the ground of alleged inconsistencies, has, in attempting to resolve the same great work into two separate works, the *Achilleid* and the *Iliad*, adopted a principle of criticism, which every man who has any practical knowledge of poets and poetry, must feel to be quite out of place. "The last two books of the poem," he says, "were probably additions to the original *Achilleid;* for the *death of Hector satisfies the exigencies of a coherent scheme*, and we are not entitled to extend the oldest poem beyond the limits which such necessity prescribes." And in the spirit of this criticism, he cuts out the whole books, from the 2d to the 7th inclusive, because the coherent scheme of an *Achilleid* is sufficiently satisfied without them, and there is no necessity for extending the oldest poem beyond the limits which such exigency requires. But a great poet is not influenced in the selection or the arrangement of his material by any exigency of this kind; that nude coherency of scheme which satisfies a mere logical mind, may omit precisely those elements which work most powerfully on his own mind, and that of his hearers; not imaginative meagreness and parsimony, but luxuriance and exuberance is his law. On the whole, the candid student of Lachmann and Grote, if he be a person of native poetical appreciation, will have no difficulty in coming to the conclusion, that the great mass of the recent sceptical objections against the organic unity of the *Iliad*, proceed on essentially perverse and oblique principles, and that the brave old minstrel has assuredly fallen on evil days, when men are eager to judge him for whose judgment he never wrote, and by canons which he never acknowledged.

The current of these remarks by no means implies that there are no interpolations in the received text of Homer. They are merely to the effect, that the sharpest scrutiny of modern criticism and hypercriticism has failed to point out any such gross incongruities in the component parts of the poem, as would distinctly indicate the separate authorship of those parts. In other words, the positive impression of an organic unity which the unlearned reader receives from the perusal of these poems, can in no wise be considered to have been nullified by the multiform endeavours of learned men to prove, that these famous poems are, to any considerable extent, an aggregation of independent and unharmonized integers. That those integers once existed in that crude state, may be assumed as most certainly true; but the poems, as we now have them, prove, in the face of the most cruel analysis, that these crude elements did, in the earliest ages of Greek culture, come under the fusing and formative influence of a great poet-mind so completely, that any attempt to resolve them into their primitive elements by the method of mere analysis must prove a failure. With this understanding, every reasonable man must be willing to admit that there are, and must in the nature of the case be, not a few extraneous additions to a work, which was a sort of public property in every body's hands for several hundred years before it was finally fixed down to the literary form in which we now have it. Some of these interpolations, of course, may be pointed out, with more or less success, according to the general laws by which incongruities in literary documents are exposed; but in addition to the presumptions for leniency of treatment already stated, the critical reviser of the Homeric text must bear in mind, that there prevails in the popular poetry of all countries a certain current tone, and common property in thought and in expression, which makes it extremely difficult, from mere internal evidence, to distinguish the original work of the great master-mind from the additions made by a skilful interpolator. Under these extremely delicate and dubious conditions, it does appear extremely strange, that Lachmann and so many other learned Germans, should talk with as much dogmatic decision about the original constituent elements of the *Iliad*, as if they had been present at their creation, and personally superintended their manufacture; and a plain man can only conclude with regard to the whole matter, that in philology, as in metaphysics, these minute investigators have, by an intense special devotion, worked themselves into a sort of chronic insanity, from which only time and the gradual operation of certain potent political and social causes may ultimately achieve their redemption.

Before we leave this part of the subject a few words may be allowed to the famous question, Whether, assuming Homer's authorship of the *Iliad*, there be not reasonable grounds for assigning the *Odyssey* to the plastic powers of a different and less mighty minstrel? Now, if this were altogether an open question, and there were no distinct and intelligible Hellenic traditions as to the common authorship of these two wonderful poems, not a few things might be urged in favour of a separate authorship which might have weight with a reasonable critic. There is a certain more mild and subdued tone in the *Odyssey*, which, along with certain points of difference in incidental matters, might be sufficient, were there no contrary evidence, to authorize the supposition of a different intellectual origin. But the great error of those who, in modern times, take upon themselves to assert the separate authorship of these works, is the groundless assumption that the general voice and tradition of Hellenic antiquity is to be taken as an element of no weight soever, in the critical estimate of such a matter. On this point we differ *toto cœlo* from the Germans, and are nothing ashamed to believe, with our learned countryman Colonel Mure, that Aristotle, Plato, and the overwhelming majority of the highest intellects in Greece, had very sufficient reasons for placing a wide gulph between the two epic poems which they agreed to stamp with the name of Homer, and the very inferior works of a cognate character, known afterwards under the name of the *Epic Cycle*. Nature did not produce twin Homers in those old Greek days, we may depend on it, any more than she has produced in these days twin Dantes or twin Shakspeares.[1] If there had been a second Homer of genius large enough to produce a counterpoise to such a work as the *Iliad*, no doubt the Homeridæ of some second Chios would have been equally eager to stereotype his memory in their composition, and to immortalize themselves with his name. But precisely, we imagine, because there was only one Homer, was there only one guild of gentile Homeridæ, and one uniform undisputed authorship of the *Iliad* and the *Odyssey* among the Greeks, till some pragmatical grammarians in meagre Alexandria (among whom a certain Xenon and Hellanicus are specialized), the prototypes of our modern Wolfians, began to nibble at imagined incongruities, and to moot the question of separate authorship. Such being the historical conditions under which the question is raised, it is manifest that the presumptions, as in the question about the unity of the *Iliad*, are all against the disintegrators; and a detailed examination of their array of minute and microscopic objections to the common authorship will, in all likelihood, bring the intelligent student, as it has brought Colonel Mure, to a distinct verdict of *not proven*. One may, indeed, urge the same objection against all the objections of the Separatists—Χωρίζοντες as they were called—that Mr Grote has urged against Lachmann and the minute dissectors of the *Iliad*. "The Wolfian theory," says that eminent scholar, "explains the gaps and contradictions throughout the narrative, but it explains nothing else." In like manner, we may say the theory of the Separatists explains the small incongruities between the *Iliad* and the *Odyssey*, but it leaves out of account altogether a more difficult matter to explain—the very remarkable congruity that exists between the whole style, tone, colour, and materials of these poems. This congruity has been pointed out with great skill and effect by Colonel Mure, also by a recent French writer, Alexis Pierron (*Littérature Grecque*, Paris, 1850), whose words, after so much heavy discussion with the Germans, the English reader will doubtless accept as a welcome relief:—

> "Mais le style, les tours de phrase, l'ordre et le mouvement des pensées! mais la versification! mais les formules consacrées! mais les épithètes traditionelles! c'est là ce que les chorizontes nègligent de comparer dans les deux poemes. Je n'hèsite pas à dire, que cent vers pris au hazard dans l'un ne ressemblent pas moins à cent vers pris dans l'autre, et pour la facture, et pour la tournure, et pour le mouvement général, que ceux-ci ne ressemblent à tous les vers qui les précèdent et les suivent. Si le style est l'homme même, comme dit Buffon, le même style c'est le même homme. Il n'y a qu'un Homère. Le style ne s'enlève pas: et, malgré tous les efforts, on ne prend pas le tour d'esprit d'un autre: on n'écrit qu'avec soi-même, mieux qu'autrui ou plus mal, aussi bien peut-être, mais toujours autrement. Sans doute c'est une grande merveille, que le même homme qui a composé l'Iliade soit aussi l'auteur de l'Odyssée. Mais le phénomène de ressemblance admis par le chorizontes est bien plus inouï encore. Le vieux Pythagoricien, Ennius, disoit que l'âme d'Homère avoit passé dans la sienne; et l'on sait quel Homère c'étoit qu'Ennius. C'est bien une autre métempsycose qu'il nous faudrait admettre, pour donner raison à ces Pythagoriciens nouveaux. Il y a une chose cent fois plus extraordinaire que l'existence d'un Homère unique, c'est l'existence de deux Homères."

After having cleared our way through this dreary accumulation of critical briars and brambles, it only remains that we state shortly what is the real character and worth of the Homeric poems, as we have them, and what is their proper and enduring place in the poetical literature of the world. And here we must start with a grateful recognition of the point of view on which our judgment of the Homeric poems has been placed by the labours of Wolf and his followers. Their error did not lie in their blindness to the true character of these productions, but in their attributing to a dozen or a score of Homers a phenomenon which finds a more obvious and satisfactory explanation in the time-honoured recognition of one. But the genuine character of the *Iliad* and the *Odyssey* as the poetry of the people, composed to be sung, not the poetry of the individual, written to be read, though previously discovered by Bentley, Vico, and Wood,[2] was never generally acknowledged and felt till it was brought forward by Wolf, and scattered over Europe by the host of enthusiastic disciples whom his genius roused into a new and vivid consciousness of a great truth. All the errors of that school, in fact, which we have been obliged to criticise in severe language, were but exaggerations and caricatures of the great truth which Wolf propounded in his *Prolegomena* of the essential generic difference between *Paradise Lost*, the epos of the scholarly man Milton, and Homer's *Iliad*, the epos of the rude Greek people. Homer lived in an age when the individual poet had not yet commenced to separate himself from the general culture of his people, after such a strange fashion as we see in the Shelleys, the Byrons, the Wordsworths, and the Tennysons of modern times. The poetry of Homer, therefore, represents the age of Homer more completely than the most popular of our highly cultivated modern poetry represents the age to which the poet belongs. The reason of this plainly is, that in the earliest ages of society, the minstrel was the only and the universal exponent of the highest moral and intellectual life of his age, and had an existence only as expressing this culture in a popular and effective way. Whereas, in later times, the man of genius rose into an independent existence, and often expressed merely his own culture, and that of a select body—more or less numerous—of literary sympathizers and admirers whom he might have the power to attach. The intimate relation that existed between the heroic ἀοιδὸς and his hearers may perhaps be best understood by comparing that sort of action and reaction which exists between the writers of leading articles in a newspaper like the *Times* and the public to whom their daily appeals are addressed. A similar case occurs in the weekly addresses of a popular preacher to a religious people like the Scotch, whose faith has not degenerated into decent formalism or unmeaning ceremonial. Herein, therefore, lies the invaluable excellence of the Homeric poems, which Wolf profoundly felt, and which made him careless about the mere personality of their reputed author—in the fact that, whether these poems be the composition of one, or of half-a-hundred minstrels, they are equally inspired by the breath of a great poetic soul, and that soul the highest life of the Greek people, at one of the most poetic periods of its existence. Recognizing this fundamental truth, the great German critic could readily let loose from his grasp a great many much-bespoken excellencies of the mere man Homer, apart from the Greek people, which were either quite imaginary, or not at all necessary to the main fact of the essentially popular and national character of the poems. In room of a great mass of foolish indiscriminate eulogy heaped up by various famous critics both ancient and modern, Wolf enunciated the peculiar excellence of the great king of Hellenic ballad-singers in the following simple and significant words:—"*Hæc carmina paullo diligentius cognita admirandam ostendant vim naturæ atque ingenii minorem artis, nullam reconditæ doctrinæ et exquisitæ*" (*Prolegom.* 12). The first great excellence of Homer's poetry, as here expressed, undoubtedly lies in its complete naturalness, simplicity, and healthiness, with an entire absence of all those faults which are the natural product of over-stimulated art in a high stage of intellectual culture. In thought, Homer exhibits nothing strained, far-fetched, or affected; in sentiment, no morbid groping, no curious over-nice sensibility in particular favourite directions; in moral tone, neither prudery nor wantonness; no uncomfortable strife between the real and the ideal, between poetry and life, between rhyme and reason. With the bard of the *Iliad*, as indeed to a great extent with all the Greek poets in the best ages, the ideal is only the highest step in the ladder of the real. In style again, we find in Homer, as in the Old Testament, nothing that smacks of the artist; there is no forced and studied concentration as in Thucydides and Tacitus; no stringing together of brilliant antitheses as in Velleius Paterculus; much less any theatrical turgidity and prepared pomp of words as in Lucan, and not a few of the later classics, both Greek and Roman, who flourished at a period when language had lost its native modesty and become vitiated, as a conceited beauty does by an assiduous contemplation of her own perfections. Closely connected with this complete naturalness of Homer, is his remarkable objectiveness, as the German critics call it—that is to say, the extraordinary clearness, breadth, accuracy, and vigour of his impressions of the external world; or, as an artist would say, his fine eye both for minute delicacy of detail and grandeur of general effect in his pictures. The reason of this lies in the fact that Homer lived in a perfectly natural state of society, when all men, and especially poets, were constantly called upon to use their eyes, not upon grey parchment and spotted paper, but upon the fresh and ever-changing variety of those soul-seizing pictures which nature and life are continually pouring in upon those whose eyes are quick and open to her fulness. In Homer there is found not the least trace of the anxiously subtle thought, the loose-floating sentiment, the cloudy imaginations, the dim speculations, the grey intangible abstractions that never fail to characterize the poetry of a later age, when the particular mental character of the poet assumes an undue prominence, and the writer wastes himself in a painful struggle to find adequate expressions for certain infinite longings and indefinite desires that have no counterpart in the external world, or in the bosom of any healthy-minded reader. Not a less remarkable consequence of the nice harmony between Homer and his audience was the honest faith and unaffected religiousness that breathes through every page of his two great works. Poets, indeed, are naturally a religious race, and, except under peculiar, harsh influences, readily harmonize with the theological belief of the country to whose highest human aspirations it is their high mission to give utterance. But in ages of high intellectual culture, when the individual often runs aside into strange tracks of private speculation, the leading minds of the day, including poets, often find themselves forced into a state of strange and uncomfortable protest against the religious convictions of the masses whom they are destined to lead; and in this way strange phenomena become visible in the literary heaven—as in the case of Euripides, Lucretius, Lucan, Lucian, Goethe, Byron, Burns, Shelley, and many more. With difficulties of this kind, which always interfere to a great extent with a poet's popular influence, Homer had nothing to do. The theology of his day was no doubt full of puerilities, and not free from contradictions; but philosophy yet unborn had not brought these puerilities and inconsistencies into a distinctly felt collision with the higher sentiments of a healthy piety in the mind of the great minstrel. Homer's piety is accordingly thoroughly serious, but withal playfully cheerful. Calvinistic readers might think him jesting sometimes; and grave German critics have been offended at the tone of the love affair of Ares and Aphrodite in *Odyssey* viii., which they confidently pronounce an interpolation;[1] but they are mistaken—Lucian did not live till 1000 years afterwards, and he wrote many clever comic sketches indeed, but not an *Iliad*. The epic poet, or great popular minstrel of a heroic age, is always a believer.[2]

---

[1] "Some people believe in twenty Homers; we in one. Nature is not so prodigal of her poets." (John Wilson, in *Blackwood's Magazine*, April 1831.)

[2] An Essay *On the Original Genius and Writings of Homer*, by R. Wood, Esq., London, 1770.

The extraordinary excellence of the *Iliad* and *Odyssey* as pattern specimens of the popular epos, may be most readily discerned by comparing them with the Niebelungen-lay of the Germans, a poem composed in a similar stage of society, and so much under the same circumstances that Lachmann actually set himself to analyse it after the Wolfian fashion, and resolve it into what he considered its constituent "small songs." In this Teutonic epos the unprejudiced reader will, along with many quiet beauties, discover an utter want of that equestrian vigour, manfulness, and fire, which never remit in the sinewy and bracing course of the *Iliad*. Homer sometimes seems to take his subject easily,—either sleeps himself, no doubt, or some interpolated Homerid is sleeping in his chair,—but he is never flat, never thin, never weak. Of the Niebelungen-lay, on the other hand, we may say that breadth, dilution, and weakness, are the characteristics; it is a German *Iliad*, and a *very* German *Iliad* indeed, as Coleridge said of the *Messiah* of Klopstock—an *Iliad* composed by an old German in his easy chair, enveloping his ungirt muse in a loose-floating atmosphere of tobacco smoke;—Homer in his slippers. But besides vigour, the Greek asserts his proud pre-eminence over the German by the healthy hilarity, and the rich sunny luxuriance of his fine Ionic temperament. One feels that these poems were written in a clime where, next to Olympian Jove, the shining Apollo was the great object of local worship. His variety and many-sidedness have been equally praised; for, though it is certainly true that there is, for our modern tastes, a very considerable superfluity of mere fighting in the *Iliad*, we must bear in mind that Homer wrote in an age when the soldier was the only hero, and for a people to whom the recital of the military exploits of their ancestors was as full of moral significance, as the trials of the Apostle Paul are to a modern Christian. Not less admirable, finally, than his vigour, his sunniness, and his luxuriant variety, are the sobriety, sense, and moderation—the truly Greek *σωφροσύνη*—that everywhere regulate, and keep within chaste limits, the billowy enthusiasm of the old minstrel. Occasionally, perhaps, when a patriotic feeling interferes, there may be discerned a little ludicrous exaggeration—as, for example, in the manner in which Hector is made to comport himself before the might of Achilles, in the 22d book; but, generally speaking, the poet's thorough naturalness and truth, keep him by a safe instinct within the nicest limits of good taste. In the Niebelungen-lay, on the other hand, as in Klopstock's *Messiah*, there is a plentiful exhibition, in the author's way, of the most appalling exaggeration. The catastrophe of the *Odyssey*, no doubt, is sufficiently bloody; but this is the divine retributive vengeance of a goddess for a long series of offences of a very gross and wanton description; and, besides, it may well be called sober and moderate when contrasted with that gigantic Cyclopean architecture of terrors cemented with streaming blood, and wrapt in flames of portentous conflagration, which forms such a grim catastrophe to the grim epos of the Niebelungen.

---

[1] On this point, and on the subject of Homeric interpolation generally, see some admirable remarks in a paper by W. Watkins Lloyd. *Classical Museum*, vol. vi., p. 387.

[2] On the interesting subject of the *Theology of Homer*, see Nägelsbach's *Homerische Theologie*, Nürnberg, 1840; and *Classical Museum*, vol. vii., p. 414. The work of Granville Penn—"*An Examination of the Primary Argument of the Iliad*, London, 1821—contains some ideas on this subject that must be regarded as high-flown and hyperbolical, and remote from the simple truth.

The works of Homer have been translated into all the notable languages of the west; seldom, however, or never, it is to be feared, with the pervading perception of his true character as a great popular minstrel, the general understanding of which great truth, as we have stated, dates in Europe only from the publication of Wolf's *Prolegomena* about 60 years ago. The best Italian translations are by Cesarotti and Monti; French, by Dacier, de Rochefort, Bitaubé, and Dugas-Montbel; German, by Stolberg and Voss; English, by Chapman, Hobbes, Pope, Cowper, Sotheby, and Newman. The principal editions are that of Florence, 1488, *curâ Demetrii Chalcondylæ;* the *Editio Princeps*, a rare and beautiful book in 2 vols. folio, of which there is a copy in the Advocates' Library, Edinburgh, and about 60 copies altogether dispersed in various parts of England; Francini, Venice, 1537; H. Stephani, Paris, 1566; Barnes, Cantab., 1711; Clarkii, London, 1729; Foulis, Glasgow, 1756-8; Ernesti, 1759; Alter Vindob, 1789; Villoison, 1788; Wofilus, Hal., 1794; Heyne, 1802; Payne Knight, London, 1820; Spitzner, Gotha, 1836; Bekker, Berlin, 1843; Baümlein, Leipzig, 1854.

For other details with regard to Homeric literature, which forms a library in itself, the student, besides Colonel Mure's great work, may consult Bernhardy's *Griechische Literatur*, Halle, 1845; Lauer's *Homerische Poesie*, Berlin, 1851, and Dr Ihne's article in Smith's *Dictionary*. (J.S.B.)

HOMER, or *Omer*, the largest dry measure amongst the Hebrews. It was in later times replaced by the *Cor*, and is estimated at 7,398,000 Paris grains. See CORUS.

HOMICIDE, the killing of a human being, is accidental, culpable, or justifiable.

Accidental, in law, implies not merely the absence of intention but of fault. A man employed at some lawful operation, and taking due care, is not responsible for unforeseen fatal consequences—as, if a gun burst; a child unexpectedly runs in the way of a carriage; or two friends wrestle for amusement, and death ensues. Such death is excusable. It is sometimes termed a misadventure. In judging, after the event, of the degree of caution which should have been used, it would be unreasonable, in every case, to require the very utmost that was possible. If two men are felling a tree, which unexpectedly falls, and one of them is killed, or if a man lays aside his unloaded fowling-piece, and, in ignorance of its being reloaded, handles it and kills his friend, it may be easy to say what would have averted the calamity; but the law is not so exacting, seeing that, in the language of an English judge, "accidents of this lamentable kind may fall to the lot of the wisest and best of men." If, however, the neglect or inattention amounts in any degree to what a jury regard as reprehensible, the case becomes

Culpable homicide, or manslaughter, meaning not accidental, and yet not amounting to murder. Cases of this kind vary from the faintest degree of culpability deserving only of nominal punishment, to guilt of the deepest dye. In them there is the absence of the intention to kill, and yet the party is amenable to punishment on account either of carelessness or wrong doing. To administer wrong medicine, neglect a fence, leave a horse on the streets unattended, or to inflict bodily injury, may happen without any intention to kill; but, if death ensue, the obvious culpability, high or low as it may be, cannot, on account of the interests of the public, be allowed to go unpunished. The last of these cases approximates to murder. If a man go a step farther, intending to inflict some severe injury, reckless of the consequences, such as beating with the declared intention of just sparing the life, or giving violent medicine to a woman to procure abortion, and death ensues, it is murder.

Murder consists in acts committed with the intention of killing, or at least of inflicting some grievous bodily injury which obviously puts life in hazard, followed by death; as, if a man strike another on the head with a hatchet, or treat him with such cruelty as denotes utter indifference whether he die or not, and he die. To chastise an infant excessively, regardless of his cries and the remonstrances of bye-standers; to shoot, intending to kill one person, and hit another; to fire a loaded gun along a street on which people are passing, though aiming at no one in particular; to cut the rope of a scaffold, by which a man is precipitated from a great height; and many such cases, where life is lost—have been found to amount to murder, as they show a determination either to kill or to do a serious wrong at the hazard of all consequences. The nature of the weapons, or means employed, such as a knife, a gun, or poison, are often conclusive; and when such is the case, jurors should, according to their oaths, do their duty to the law and to their country. Where the crime is proved, it is not sufficient to say that the manslayer was excited to frenzy by some fancied wrong or inadequate cause, and acted with little premeditation, because he was bound to maintain the mastery of his passions,—though no doubt his moral guilt is exceeded by that of the assassin, who, for hire or revenge, waylays and stabs his victim. On the other hand, if it appear that a man acted under a sudden impulse, occasioned by some intolerable wrong, he will not be held guilty. On the contrary, the killing will be regarded either as culpable or justifiable homicide, according to its circumstances. For example, if a man be unwarrantably assaulted with violence and indignity, as, by a horse whip, pulling his nose, or the like, and he inflict, in the sudden transport of passion so excited, a mortal wound on his assailant, the killing will be attributed to human frailty, rather than to recklessness or malice, and may be regarded merely as culpable homicide; but he will not be allowed after the assault is over to take satisfaction at his own hand, and kill his assailant. To do so is to commit murder. In no case will the law, after almost the briefest lapse of time, permit the indulgence of revenge. An adulterer, detected by the husband in the act, may be killed; but if he escape, and be afterwards met and killed by the husband, such killing is murder. The shortest interval, after any provocation, destroys such a defence; as, if a man, injured even to the effusion of blood, should search for a gun, and follow and shoot the party who had assaulted him; because the interval afforded an opportunity for the exercise of reason, and the law could have been appealed to. An English judge expressed what is the law both of England and Scotland when he said, "in all possible cases homicide, upon a principle of revenge, is murder." One thing is quite fixed, that as contumelious words will not justify blows, so neither will blows with the hand justify the use of a knife, or other lethal weapon. Wherever the use of a lethal weapon is not justified by dire necessity, in order to preserve a man's own life, killing by its use is murder. Accordingly, the law both of England and Scotland agree in this, that no attempt to steal or to trespass will justify a man whose life is not in imminent hazard, in the taking of life. On a similar principle, to kill a poacher, or to place a spring-gun to protect a garden, and it kills, is murder. It would, indeed, be strange if the law permitted a private party to take the life of another, for an offence which, on conviction after a legal trial, it would not punish with a penalty so dreadful.

To warrant a conviction, it is necessary that death result directly from the injury, or from its natural, and not remote or merely probable consequences. If a wounded man die from grossly erroneous treatment, or from unnecessarily exposing a wound, so as to irritate it into a mortal complaint, it would be hard to visit his assailant with the penalty of murder. On the other hand, if the wound be the direct cause of death, though if a surgeon could have been got on the instant, the life would probably have been spared, the assailant must take the consequences, because he had no right to put life in hazard; and, on the same principle, it is murder to kill a man apparently dying from some mortal disease, because no man has a right to abridge the life of another even by a moment, or to cut off the feeblest chance of recovery.

It is not necessary, in order to warrant a conviction, that a man perpetrate murder with his own hand. If he hire or assist another to commit it, or if he furnish the means, or watch for the protection of the murderer while the crime is being committed, he is, both in law and in reason, accessory to the commission of the crime, and is most righteously amenable to punishment as a murderer.

The appropriate punishment of murder is death. Long before the moral law was given from Sinai, the Divine Being declared that "whoso sheddeth man's blood, by man shall his blood be shed;" and we think that the natural dictate of the well-regulated mind is to repel the sophistries by which this solemn declaration is sometimes sought to be evaded. So repulsive is murder to the Great Author of life, that, under the law which He gave to Moses, He allowed no sacrifice to be provided, nor ransom to be taken, for the life of a murderer—and even the accidental manslayer was compelled, for the safety of his own life, to remain within one of the cities of refuge while the high priest of the time was alive. It is sometimes questioned whether capital punishment should take place publicly, or within the precincts of the prison, in presence of a number of witnesses provided to attest its execution. The latter opinion is approved by some, as having a less hardening tendency on the minds of the populace. To remove the felon from the bar of earthly judgment, to immure him within the walls of the prison, from which he is not to return alive, and to detain him till the determinate moment at which he shall find himself at the bar of the Judge of all the earth, may produce in the minds of the thoughtless something more fearfully solemn than the parade of a public execution, during which, in our sympathy for the sufferer, his crimes may be forgotten. But however that question may be settled, and so long as the declaration of the Divine Being, "I will put my laws into their mind, and write them on their hearts," is respected by his creatures, we believe that the punishment of death for the most fearful of all crimes cannot be relaxed without multiplying the number of victims hurried into eternity, without even the murderer's privilege of time to prepare for their final account.

The punishment for manslaughter or culpable homicide is, fine, imprisonment, or transportation, in the discretion of the judge according to the degree of guilt; and the offender is further left to the issue of an action of law for civil reparation at the instance of the widow and next of kin of the person whom he has killed.

Homicide is *justifiable* when it is occasioned by unavoidable necessity. Illustrations of this are daily afforded by soldiers and sailors in battle, or in the necessary defence, when on duty, of their post or their arms—judges pronouncing, and inferior officers executing legal sentences of death—and magistrates or other officers killing when such is the only mean of suppressing a riot or breach of the peace. In the case of private individuals also, the infliction of death becomes justifiable when no other means of defence remain against highway robbery, housebreaking under night, or assaults involving danger of life, or in the case of a woman as a last resource in defence of her chastity. The justification, however, will only avail when matters have come to an extremity—and certainly not either before the danger has reached that point, or after it has passed away. If the danger be over, killing becomes revenge, and is justly regarded as murder. Even the clearest necessity of killing in defence will be unavailing, if it was brought about by a man's own criminality, as by his culpably irritating and rousing another by wanton and unwarrantable provocation or cruelty to attack him. It becomes, therefore, always of importance to ascertain all the circumstances connected with the beginning and progress of an assault, and by whom the first blow was given.

Very delicate questions have arisen in the cases of officers of the law bound on behalf of the public to execute a legal warrant. Their position is different from that of private individuals, in this respect, that they incur responsibility if they fail to do their duty. Of course, if in the discharge of their duty their lives are brought into peril, they are justified, like any private individual, in killing; but they differ from private individuals in this, that they may be required to do the very thing, under the sanction of law, that puts their lives in danger. If persons in a smuggling vessel do not desist from attempting to escape when hailed by a known revenue cutter, it is lawful to enforce compliance by firing, for in such a case the fleeing to defraud the revenue is just that resistance which it is the duty of the officers of the law to overcome by the only means in their power. But if, on coming in contact with those whom they are required to apprehend, they be the first to resort to lethal weapons, or if, under any circumstances, they use them unnecessarily, they will be liable for the consequences. It is murder for an officer to kill a person flying from the execution of a civil process, or even of a criminal warrant for an offence not capital, or for an assault not at the time known to involve danger of life. It is only the deep interest which the public has in the punishment of those who commit the highest crimes, that justifies an officer armed with a criminal warrant (if indeed the law of Scotland will justify him) in killing such a criminal when fleeing, who might otherwise altogether escape. The requirements of military law are necessarily more strict, but these may be noticed in another place.

In the preceding remarks we have abstained from taking any notice of the absurd and criminal practice of duelling, that subject having been already fully treated. See DUEL.

(M. L.)

Homily || Homœopathy.

HOMILY (ὁμιλια, an assembly), a plain and homely discourse upon some point of religious faith or duty. This term was adopted in the church to indicate the practical nature of Christian discourses as contrasted with the speculative and purely ostentatious harangues of the philosophic schools.

All the homilies of the Greek and Latin fathers are from the pens of bishops, because, in the first ages, they alone were permitted to preach. The privilege was not ordinarily allowed to priests till towards the fifth century. St Chrysostom was the first presbyter who preached regularly. Origen and St Augustin also preached, but it was by a peculiar license or privilege.

Photius distinguishes a *homily* from a *sermon* in this, that the homily was delivered in a more familiar manner, the prelate interrogating and talking to the people, and they in their turn answering and interrogating him, so that it was properly a conversation; whilst the sermon was spoken continuously in the pulpit, after the manner of the orators.

The practice of compiling homilies, which were to be committed to memory, and recited by ignorant or indolent priests, commenced towards the close of the eighth century, when Charlemagne ordered Paulus Diaconus and Alcuin to form homilies or discourses upon the Gospels and Epistles, from the ancient doctors of the church. This gave rise to the famous collection entitled the *Homilarium of Charlemagne*, which, being followed as a model in many productions of the same kind, composed by private persons, contributed much to nourish the indolence, and to perpetuate the ignorance, of a worthless clergy.

The English book of homilies is a collection of plain sermons on the doctrines of the gospel, especially with a view to illustrate the principles of the Reformation. The first part was published by Cranmer during the reign of Edward VI.; and the second was added by order of Convocation during the reign of Elizabeth.

HOMŒOPATHY, a system of medical practice, introduced by Samuel Hahnemann into Germany in the end of last century, and having, in the present day, adherents in most European countries. The homœopathic system was reduced by its founder to a very simple expression, or elementary therapeutical law, *similia similibus curentur—i.e.*, let like things be treated by like. In other words, it is asserted that a disease, having certain external manifestations or symptoms, is to be treated by the administration of a remedy, or a succession of remedies, which have the power of originating similar symptoms in the healthy body. The name *Homœopathy* (from the two Greek words ὁμοῖος, *like*, and πάθος, *a morbid state*, or perhaps from the compound word ὁμοιοπάθεια, *a similarity of feeling*), is expressive of this relation between the effects of the remedy and those of the disease for which it is presumed to be a cure. Hahnemann was fond of contrasting the simplicity of the homœopathic system with the complexity of the prevailing medical doctrines, which, he alleged, instead of following the indications of nature by regarding disease as a collection of symptoms, was engaged in a fruitless search into its proximate or essential causes; remedies being administered, not from their bearing any relation to the evident symptoms, but from a presumed power over the hidden causes of disease. The system so characterized, Hahnemann termed allœopathy, or allopathy (from ἀλλοῖος, *different*, and πάθος). He admitted also another possible therapeutical system, viz., *Antipathy* (from ἀντὶ, *opposed to*, and πάθος), comprising those cases in which a remedy was selected on account of its producing in the healthy body symptoms of a kind opposed to those of the disease. Of this method, Hahnemann professed to find numerous examples in the practice of medicine in all ages. He even found it laid down as a rule (*contraria contrariis curentur*) in some of the Hippocratic writings, and constantly refers to it as an established method against which he protested as fallacious, ineffective, or, at best, only palliative. Homœopathy, according to Hahnemann, is not merely a more certain or more effective method of cure than either of these competing systems; it is, on the contrary, the only method by which disease ever has been, or ever can be, truly eradicated by art. It is in theory a universal as well as an exclusive method; and all the other principles on which medical men have from time immemorial been accustomed to act in the treatment of disease stand condemned by its acceptance.

It would be easy to show that with Hahnemann himself the homœopathic theory was expressly set forth as waging an internecine war with all previous medical doctrine. The vilification of ancient and contemporary medicine as a system or a science, and the almost equally unlimited condemnation of its results as an art, form in fact the key to his doctrine, the corner-stone of his system. Medicine is to him a "fatal art," which has never, except by accident, rendered a service to suffering humanity. It can be continuously practised only by those whose conscience is seared, and whose mental discrimination is destroyed by long-continued persistence in mischief; in all others, it reduces itself to the administration of *placebos* without efficacy, and of which the best that can be said is that they do little harm. But it was inconsistent with the justice and mercy of Divine Providence to leave mankind in this miserable plight. The discovery of a sure and simple way of treating all diseases must be possible, if God is a beneficent being, and not a ruthless tyrant. Now, there are only three possible ways of using remedies. For, *firstly*, all that we know of diseases, and of remedial agents, is founded on a knowledge of their palpable effects or symptoms; and, *secondly*, the symptoms of the remedy (its effects upon the sound body) must be either similar to (*similia similibus*), or opposite to (*contraria contrariis*), or different altogether from, those of the disease. Of the systems founded on these data, the last two alone have been hitherto tried; and multiplied experience having proved that allopathy and antipathy are equally erroneous and equally destructive, homœopathy follows as an inevitable consequence; and was thus, in fact, as Dr Henderson says, reasoned out by Hahnemann "before a single testing experiment had been tried."

We carefully avoid exaggerating, though undoubtedly we greatly condense, the argument of Hahnemann, as it appears in several of his works, when we thus state it. Were we to enter on what might be called the metaphysics of his system, we should greatly exceed our limits; still more so were we to devote any space to the consideration of individual instances, or to the quotation of individual passages. It must be apparent to any intelligent reader, that the system blocked out above is that of a fanatic, not of a severe inquirer into nature; that it begins and ends in assumptions, of which it is difficult to say whether the first or the last be the more extravagant. It is surely not too much to suppose, in opposition to Hahnemann, that an art which has existed, and has been accumulating the elements, at least, of science, in the experience of several thousand years; which has laboured assiduously wherever there has been sickness and suffering, with certainly not less of disinterested feeling, and certainly not more of wickedness or of stupidity among its professors, than falls to the common lot of humanity in almost all professions and callings—that such an art may have had some little foundation in truth, some glimpses of principle, some insight into the laws which regulate the human frame in health and disease. Equally certain is it that these principles and laws have not been asserted (like those from which Hahnemann endeavours to deduce his philosophy) to be final and universal. If the choice be only between "allopathy" or "antipathy" and "homœopathy," as Hahnemann asserts, we feel little disposition to pronounce any comparative opinion; but we place ourselves

Homœopathy.

readily on the side of limited but reasonable knowledge, and experience tried by ages, against extravagant credulity and bombastic self-assertion.

The writings of Hahnemann are, for the most part, violent and outrageous polemics, not always without plausibility, against the systems which he caricatures under the names of allopathy and antipathy, followed or accompanied by statements of an equally extravagant kind in favour of the law "similia similibus curentur," which he everywhere treats as a pure and unadulterated truth, admitting neither of qualification nor of question. The practitioners who act upon an uncertain or imperfect apprehension of this truth, and who attempt, in any degree, to reconcile their practice with the traditional doctrines of the art, Hahnemann treats with a contempt and dislike to which even his dislike of allopathy itself is obliged to yield. This "bastard homœopathy" is, in his view, as discreditable as it is dangerous. Those who practise it are in no sense homœopathists, and are deserving of the strongest condemnation. It is a crime against homœopathy to give even the semblance of an allopathic remedy; and Hahnemann does not hesitate to confess that he has on this account given up the use of some of those simple palliatives, whose value he had attested by his own experience before he embraced homœopathy, but whose use he considered as being at once superseded by the new system, and inconsistent with its principles.

A system like this must of course be tried as a whole. It must stand or fall by its own tests. If true, it demands nothing less than that all previous systems shall give way to it. But, on the other hand, if it errs in one point, it is guilty of all. Hence the question between the homœopathists and their opponents cannot be settled by an array of instances on the one hand, or an array of authorities on the other. A thousand instances of like curing like will not prove the law universal in the face of half a dozen opposing facts. But all the authorities in the world will not disprove homœopathy, unless they can succeed in establishing a system or a fact which is at variance with it.

Tried by this simple issue, the strength and the weakness of homœopathy (or at least of Hahnemann's homœopathy) are at once apparent. Its strength lies in the confessed inability of ordinary medicine to oppose to it any system as simple, and apparently as complete, as its own; its weakness, in the total insufficiency of its alleged instances to support the enormity of the postulate. To the mind which must at all hazards have a complete and universal system, it may be conceded that homœopathy is no worse than any other, and, in connection with its ordinary practice of infinitesimal doses, less hurtful than many systems. But to the mind which regards all systems as subject to the rigid criticism of facts homœopathy must ever appear one of the most unfounded and monstrous of delusions.

In saying that "like cures like" Hahnemann uses a form of expression which (especially in Latin) bears a very respectable resemblance to the enunciation of a great natural law. But examine that expression, and, still better, try it by instances. What is "like," and what unlike? Polonius thought that Hamlet's cloud was like a camel, a weasel, and a whale, in turn; it was probably as like the one as the other. One man sees a likeness between certain members of a family; another cannot see it; a third sees it at one time, and fails at another. In one sense all men are more or less alike; in another infinitely varied and dissimilar. In the region of ideas, the poet and the wit equally see resemblances which duller minds fail to appreciate. The naturalist discovers likeness in those objects which to the ordinary sense are the most dissimilar; while flowers and minerals, birds and fishes—so like that the common eye cannot distinguish them from each other, or can distinguish them only with effort and by dint of instruction—are found to be placed far apart among the genera and species of the careful and analytic observer. In short, no feature of objects is more liable to be differently appreciated from different points of view, and by different minds, than precisely this one of external resemblance.

The force of this argument, in its application to the homœopathic law, is all the greater that Hahnemann does not admit *identity* between the symptoms of the disease and the effects of the remedy as constituting a reason for its therapeutical employment. On the contrary, identity is destructive of the alleged homœopathic action, which is found to exist only in connection with great similarity. But it may well be asked if absolute identity be not, in such a case, merely the greatest possible amount of similarity.

It is well known to the man of science that nothing is so apt to mislead the mind as the tracing of analogies. Yet the whole basis of the law, *similia similibus curentur*, is nothing but a series of analogies so vague, and sometimes so preposterous, that in any department of natural history they would be rejected as unworthy the name of science. The truth of this assertion will be admitted by almost any man (not being a professed homœopathist), who will examine the assertions recorded in regard to only a few articles of the homœopathic materia medica. But as our limits forbid this inquiry, it may suffice for the present to mention that a large proportion of Hahnemann's instances of the homœopathic law are adduced from the writings of physicians who not only were unaware of the resemblance between the symptoms of the remedy and those of the disease, but, according to Hahnemann, prescribed those very remedies upon the antipathic or allopathic principle. Were it true (as it is not) that ordinary medical practice was founded on either of these alleged principles, there would be little or no difficulty in defending one or both of them by a reference to the very same remedies and the very same diseases as are adduced by Hahnemann to prove the homœopathic law. But in placing his so-called therapeutical law upon a basis of mere analogy, Hahnemann has scarcely betrayed a greater misconception of true science than he has of medical history, in ascribing to his opponents a practice founded on "allopathy" or "antipathy,"—names as entirely unknown to medical science as "homœopathy" itself.

It may safely be alleged that the favour shown to homœopathy as a system by a certain portion of the public depends much more on the supposed success of its practice than upon the validity of the evidence adduced in support of its law. Homœopathy is embraced, not as a philosophical truth, but as a method of dealing with the minor ills which flesh is heir to, certainly much more agreeable, and presumed to be not less safe, than that of ordinary physic.

This idea is not entirely without foundation, if ordinary physic be conceived to be nothing else but a succession of bleedings, purgings, and blisterings. That medical resources have often been abused, and that a large amount of suffering and inconvenience, if not of disease and death, have sprung from the too active use of remedies having acknowledged power both for good and for evil, no one will be disposed to deny. The employment of infinitesimal or very minute doses by the homœopathist has undoubtedly tended to make that system the natural refuge of those who have suffered from the *nimia diligentia medici*. And as a very considerable portion of diseases require little else than dietetic and hygienic means for their cure, when cure is possible, even the pure homœopathist does not always fail so notoriously as to discredit his system. Many diseases, besides, are well known to be self-curative; as the most ancient and celebrated of the Greeks has expressed it, "Our natures are the physicians of our diseases." And in those cases which plainly require the assistance of active remedies there are now-a-days few homœopathists who are not found willing to cast aside their system so far as to employ at least the simpler and safer varieties of active drugs after a

Homœopathy.

fashion confessedly not homœopathic. With such practitioners, homœopathy, with its infinitesimal doses, qualified by the administration of active drugs in cases of emergency, becomes merely ordinary practice reduced to the minimum of activity; and, as such, may be a much better practice than the opposite extreme. But, on the other hand, such "bastard homœopathy" would, as we have seen above, have been most severely condemned by Hahnemann. It is, in fact, homœopathy in nothing but the name.

The doctrine, or rather the practice, of infinitesimal doses, is undoubtedly one of the most curious aspects of homœopathy, as it is one of the most singular phases of human opinion in matters medical. The ordinary and universal persuasion that remedial substances act upon the system in something like a direct proportion to the quantity in which they are introduced into it, is not indeed opposed by Hahnemann, so far as the physiological effects of these substances are concerned. It is not denied that one hundred grains of arsenic, for instance, are more likely to kill than the hundredth part of one grain. But it is maintained that the powers of remedies over disease are so distinct from all their physiological, and, indeed, all their material properties, as not to be subject to the same conditions of increase and diminution. The curative property of a remedy is, according to Hahnemann, developed in a much higher degree by an inconceivably minute than by a palpable dose. The latter, indeed, interferes directly with the cure; because the *symptoms* developed by the remedy, being similar to those of the disease, invariably tend to its aggravation in a degree corresponding with the amount of the dose and its homœopathicity. It was, indeed, this constant aggravation of the disease under homœopathic remedies which first led Hahnemann to reduce his doses to impalpable quantities as an indispensable condition of safety in their use. So bigoted was he to his system that he did not see even in this contradictory result of his own experience an argument against his alleged universal law!

The extent of these infinitesimal dilutions is such as to be inconceivable by the human intellect; they can only be expressed in the technical abbreviations of the arithmetician, and even then are with difficulty carried in the memory. Thus in the thirtieth dilution one grain of the resulting liquid contains one decillionth of a grain of the remedy, or 1,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000,000th part of the whole. If one entire grain of medicine were thus diluted, it may be shown, by accurate mathematical computation, that the quantity of fluid required for the purpose would form an ocean *one hundred and forty billion times as large as our whole planetary system;* or if a solid substance were used, so that a single globule might contain a decillionth of a grain of the remedy, the original grain thus diluted with inert matter would be equal in weight to "*one hundred and forty billion spherical masses extending from limit to limit of Neptune's orbit*," or to "*many hundred spheres, each with a semidiameter or radius extending from the earth to the nearest fixed star.*" With which calculations from Dr Simpson's work on homœopathy, revised and corrected as they are by Professor Kelland, we trust our readers will be satisfied. Yet the homœopathic dilutions recommended by some of the more modern homœopathists far exceed the thirtieth in minuteness; and Hahnemann himself often recommended the simple smelling (olfaction) of a globule diluted as above!

Hahnemann was born in 1755, at Meissen, on the Elbe, near Dresden. His father was a painter on porcelain; and his early education, as well as his medical studies, were pursued under considerable pecuniary pressure. He began thus early the occupation which for a long time afterwards was one of his chief sources of emolument, viz., translating from the English. He graduated at Erlangen in 1779, and soon after this he commenced practice and married. He did not at first succeed in gaining public confidence; and indeed, for a good many years before the great arcanum was discovered he had almost no actual practice, and occupied himself chiefly with translations, and with chemistry, of which latter science he made some useful and profitable applications. He himself said, years afterwards, that he had retired from practice from conscientious motives, finding that he could not reconcile the responsibilities of medicine with his scepticism as to the remedies in use. It is rather inconsistent with this view of the matter, however, that he was busily engaged in propagating with his pen those very therapeutical doctrines which he thought it a sin to apply in practice. He was still translating very largely, and in 1790 was engaged on Cullen's *Materia Medica*, which had appeared in England the previous year. During that previous year, too, he had written his original work *On Syphilis, and on the Mercurius Solubilis Hahnemanni*, a work which presents no trace of scepticism, but, on the contrary, an all-devouring faith in the drugs then in use. It was from Cullen's *Materia Medica* that he obtained the suggestion as to the homœopathic use of Peruvian bark. After some temporary engagements he removed to Königslutter to begin practice in 1795. He continued as before to be a copious writer, and in 1796 produced his first attempt to expound the homœopathic law. In 1799 his practice of dispensing his own medicines brought him into collision with the apothecaries of the place, who managed to bring the laws to bear on a method of practice so much opposed to their vested interests as tradesmen. The consequence was that Hahnemann left Königslutter, and that the unjust restrictions to which his practice had been subjected produced the usual fruit of persecution—sympathy and notoriety, both for the man and for the doctrines, which he now began to put forward with a bolder front than hitherto. From Königslutter he went to several places in succession, and ended by settling in Leipzig in 1810. In this year he published the *Organon der Heil-Kunst;* and in the next a volume on *Materia Medica*, containing numerous "provings" of drugs on himself and on others. The completion of this work occupied him till 1821. He became at Leipzig a successful practitioner, and left it only in consequence of a persecution like that to which he was subjected at Königslutter. He next went to Anhalt-Coethen, where the reigning prince was one of his warm partizans. He remained here, occupied with practice and with his pen, till 1835, when, at the age of eighty, he married a second time, or rather was married and carried off to Paris by an enthusiastic young lady, Mlle. Mélanie d'Hervilly, who was anxious to secure for the French capital the benefits of homœopathy and the person of its founder. He died at Paris on the 2d July 1843, having engaged in a large practice during the eight years he resided there, in which he was assisted by his wife and daughter. Madame Hahnemann continued to practise homœopathy after the death of her husband, notwithstanding an attempt in the French courts of law to restrain her as an unlicensed practitioner; on which occasion she received the powerful support, in the Chamber of Deputies, of M. Montalembert, who argued, in a speech of great eloquence and power, against restrictions on medical practice. (W. T. G.)

Homonyms || Hondekoeter.

HOMONYMS, words agreeing in sound, but differing in signification.

HOMOOUSIANS, a name applied to the orthodox, indicating that they held the Father and Son in the Trinity to be of the same nature, thus distinguishing them from the Arian party, who were called Homoiousians, and who held only a similarity of nature to subsist between them.

HONDEKOETER, Melchior, a distinguished Dutch animal-painter, was born at Utrecht in 1636. His father and grandfather had both made for themselves a considerable name in that walk of art, but their fame was soon totally eclipsed by his. Though he painted most kinds of animals, his favourite subjects were cocks, hens, ducks, and peacocks, which he delineated with wonderful correctness and truth to nature. It is said that he trained a cock to stand in whatever attitude he desired, and to remain in that posture for several hours at a time without moving a muscle. The landscapes which he introduced as back-grounds to his pictures were like them wonderfully true to nature, and finished with a delicate lightness and transparency of touch that harmonized admirably with the subject of the piece. In his walk he has never been rivalled, and his genuine pictures, of which the best are in English collections, often fetch high prices. Connoisseurs have less difficulty in detecting copies or forgeries of his pieces than of any other of the old masters. Hondekoeter died in 1695 at the age of fifty-nine.

HONDURAS, British, *Belize* or *Balize*, a British settlement on the east coast of Central America, between N. Lat. 15. 54. and 18. 30., and W. Long. 88. and 89. 30. It is bounded on the N. by Yucatan, W. and S. by Guatemala, and E. by the Bay of Honduras. It has a coast line of about 200 miles between the mouths of the Hondo and Sarstan, and is about 100 miles in breadth.

This coast was discovered by Columbus in the year 1502, but little that can be relied upon is known of its early settlement. The abundance and fine quality of the wood, particularly mahogany and logwood, seem first to have drawn attention to it; and at a pretty early period it was occasionally resorted to by wood-cutters. But the first permanent establishment of British wood-cutters was made at Cape Catoche by some adventurers from Jamaica, whose numbers increasing they extended as far S. as the River Belize, and as far W. as the neighbourhood of Campeachy. The Spaniards, however, did not quietly submit to this usurpation of their territorial dominion. Several expeditions were fitted out against the settlers, but they were uniformly unsuccessful; and on two occasions, in 1659 and 1678, so complete was their discomfiture, that the town of Campeachy itself was taken by the logwood-cutters, with only the assistance of the seamen engaged in the trade. This last repulse occurred eight years after a treaty had been concluded with Spain, by which the territorial right of Britain to the occupancy of Honduras was generally, although not specifically, embraced. The successes of the settlers aroused the jealousy of the Spaniards, and led to a renewed discussion of their right to the territory which they occupied. This would appear to have been again generally admitted; but the Spaniards finally succeeded in driving the woodmen from the Campeachy shore, and confining them to the limits of the present settlement. An attempt was again made in 1718 to dispossess the British of the territory on the River Belize; but the firmness of the woodcutters deterred the Castilians from effecting anything, except the erection of a fortification, which in a few years they abandoned. In 1754 an expedition was undertaken to exterminate the colony; but by a treaty of peace concluded in the year 1763, the Spaniards were compelled to admit the right of occupancy to the British colonists, which, however, they subsequently attempted to annul. In 1779 the Spaniards again attacked the settlement, and after destroying property to a considerable amount, they took a number of the colonists prisoners, and marched them off in irons to Merida, whence they were shipped to the Havannah, and there confined till 1782. In 1784 Britain obtained from Spain a specific grant of "the lands allotted for the cutting of logwood;" and in 1790 an act of parliament conferred on Belize all the privileges of a British colony. The last attack on the settlement was made during the war in 1798, but the expedition, which consisted of 3000 men, was gallantly repulsed; and since that period the colony has remained undisturbed by foreign aggression.

The coast of the Bay of Honduras is low, and the shore is studded with a number of low islands or keys, which, however, are verdant. As we recede from the coast, the land rises into a bold and lofty country, interspersed with rivers and lagoons, and covered with gigantic forests. The lagoons or sheets of water, and the falls and rapids of the rivers, constitute sublime and beautiful features in the general aspect of the country. The Hondo River, which forms the northern boundary, is a fine stream. A few miles S. of it is the New River, which has its source in an extensive lagoon. The Belize has a N.E. by E. course of above 200 miles, and discharges itself into the Bay of Honduras by two mouths about 3½ miles apart, the southern branch dividing the town of Belize into two parts. The river and lagoon of Manatee, which is situated 10 leagues S. of Belize, is considered as extremely grand. At about a mile from the mouth of the river is the lagoon, a magnificent sheet of water, extending for several leagues in a northerly direction. In many places lofty hills ascend from its margin, overtopping large valleys and wood ranges of great extent, where the jaguar, capybara, armadillo, large weasel, opossum, racoon, and several species of deer, abound. Amongst the feathered tribes there are numbers of quails, plovers, pigeons, pheasants, and wild turkeys. The deficiency of streams amongst the mountain ridges is supplied by the presence of large marshy spots or shallow ponds, the banks of which are frequented by almost every species of water game. Fish abound during a great part of the year in these ponds, but the latter dry up in the season of drought, and then vast flocks of sea-fowl congregate around them to prey upon the fish which have been left dry by the evaporation of the waters. The alligator is also a frequent visitor; and, to partake of this repast thus yearly provided for him, he has been known to traverse trackless wilds, and make long journeys into the interior. The rapids of the Manatee commence about 8 or 10 miles from the lagoon, and the high rocky banks of the river assume a romantic and beautiful appearance. Further on there is a rapid of about a quarter of a mile in length, and of considerable acclivity. A cluster of beautiful caves, through which the river winds its way, and beneath which the traveller must pass, is next reached. They have been described as equally singular and grand. "These magnificent natural excavations of the mountains are semicircular at the entrance, and about five yards in diameter. Within the cave the arch rises to the height of 100 feet, and leads to another low arch, which being passed, a second cavern of large size opens, beyond which is a third with a circular orifice, through which the river enters. During the floods the mouths of the caverns are filled with water, which boils up with prodigious fury, and thus detains travellers many days before they can pass through the caves or tunnels. In the rainy season, as the water increases on the upper or inland sides of the mountains, the river forces its passage through the interstices and openings in its sides with tremendous noise, forming an indescribably grand cascade of from 40 to 50 feet high, issuing from an hundred orifices." Of the other rivers of Honduras little is known.

The country is technically divided into the Pine and the Cahoun ridges. The soil of the former has a substratum of loose reddish sand, and its indigenous products consist of those varieties of vegetation the assimilative powers of which are strong and perennial. Extensive prairies expand over this soil, and the pine, from which it derives its name, is extremely abundant. The soil of the Cahoun ridge consists of a deep loam, capable of growing every species of European as well as of tropical aliment. Its fertility occasions the growth of much brushwood, and it is covered with the wild cotton tree and other giants of the forest.

Fruits, spontaneously produced, are exceedingly abundant, and consist of oranges of excellent quality, shaddocks, limes, mangoes, melons, pine-apples, water-melons, avocato pears, cashew, cocoa-nuts, and many others. They are all found in the neighbourhood of Belize, but are sometimes brought in large quantities from more elevated plantations. The mahogany and logwood trees are at present the staples of Honduras. The former is found best in elevated situations; and growing generally solitary, it is discernible at a great distance from the yellow hue of its foliage. It is cut down at about 12 feet from the ground, and when felled the logs are dragged to the banks of the streams and floated down in rafts. The boughs and limbs are said to afford the finest wood, but it is the size that is principally looked to in Britain. The logwood is found in low swampy grounds, growing contiguous to fresh-water creeks and lakes, on the edges of which the roots, the most valuable part of the wood, ramify. They are felled during the dry season, and carried off when the wet season has laid the ground under water. There is another valuable tree called the *Pinus occidentalis*, which grows to the height of 60 feet, and covers many thousand acres of country. The pine-wood contains an immense quantity of tar and turpentine, and is consequently highly inflammable. In this respect it is very valuable to the poor, who make torches of it. It likewise powerfully resists decay, and is in consequence much used by builders. The cahoun or cohoon tree yields a valuable oil, which, when unadulterated, is almost colourless, destitute of any disagreeable taste, and when burned as a lamp oil it emits a beautiful palish flame without smoke or smell. There are various other kinds of wood of beautiful vein and close texture, such as iron-wood, clay-wood, rose-wood, palmaletta, and the like. Amongst minerals, strata of fine marble and formations of alabaster are known to exist. Several valuable specimens of crystals have been found, and gold has occasionally been detected in some of the streams. Labouring Creek, which lies on the Belize, about 100 miles inland, is remarkable for the petrifying properties possessed by its waters. They have also a powerful cathartic effect on strangers, and when applied externally to an ulcer have a healing property.

The country abounds with all kinds of animals fit for the food of man. Except in very rough weather, the supply of salt-water fish of excellent quality is abundant. The common green turtle, when in a healthy condition, is a staple commodity in the market. The hawksbill turtle is often five feet long, and weighs from 200 to 250 lbs.

Belize, the capital of the settlement, stands on a low flat shore immediately open to the sea, and guarded by numerous small islands, densely covered with trees and shrubs, and so similar as to render the navigation extremely difficult. It is farther divided into two parts by the river, which is crossed by a substantial wooden bridge of 220 feet span and 20 feet in length. The part of the town which is situated upon the S. or right bank of the river, along the eastern edge of a point of land, is completely insulated by a canal on its western side, which runs across from a small arm of the sea, and bounds the town on its S. side. The houses are about 500 in number, and are in general well built, spacious, and even elegant. They are for the most part constructed of wood, and raised 10 feet from the ground on pillars of mahogany. The streets are regular, and cross each other at right angles. The main one runs in a north-easterly direction to the bridge from the government-house, which is situated on the S.E. point or angle of the island on the right bank of the river, and bounded on the S. and E. by the sea. Behind the government-house is the church, on the E. side of the main street. The whole town is embowered in groves and avenues of the cocoa-nut and tamarind trees. Fort-George is situated about half a mile from the river, on a small low islet.

In the neighbourhood of Belize the natural heat of the climate is tempered by the sea breezes that prevail during nine months in the year, so that, even in the hottest season, the thermometer seldom rises above 83° Fahr., and during the wet season it sinks to 60°. In June, July, August, and September, heavy and frequent rains fall, and these are the most unhealthy months of the year, from the decomposition of animal and vegetable matter in the adjacent lowlands and swamps.

There are various classes of society in this settlement, including Europeans, coloured people, Indians, and Mosquito men. The blacks of Honduras are distinct from the aborigines of the country, being of African descent. In general they are inclined to indulge those low propensities which are exhibited in a state of barbarism. Having been derived from various regions, they still retain all their national peculiarities, and keep themselves distinct from every other tribe. The blacks, as a body, have upon the whole little intelligence, and their dulness of comprehension is remarkable. It is asserted, however, that some of them exhibit an originality of talent and a degree of mental activity little inferior to their European brethren. They are much attached to their country, and with a native of his own land a Honduras black will share his last plantain. The *coloured* population has resulted from the intercourse of Europeans with Africans or Indians. They of course, morally speaking, assume a medium status, and partake more or less of the qualities of black and white, according to their distance from either. The *Mosquito Indians* abound in the colony. They are remarkable for a fine muscular formation of body, but in their countenances they exhibit an utter destitution of intelligence, and their habits are most barbarous. They acknowledge the existence of a good and evil spirit; and the little power of thought which they possess is displayed in their conduct towards their deities. The good spirit is neglected, because, say they, his goodness is so great that nothing is to be feared from his wrath, whilst, on the other hand, the evil spirit is propitiated, in order to deprecate his malevolence. The whole wealth of a Mosquito man consists in his canoe, paddle, and harpoon. With these he satisfies the cravings of nature, and his grovelling nature asks for no more. The *Indians*, the real aborigines of the place, are a timid, inoffensive race, apparently more under the influence of instinct than of reason. They perform the most astonishing journeys through woods, as trackless as the sea, and impervious to all but themselves with infallible correctness of direction and amazing rapidity. Although free from vindictive or malicious propensities, they are addicted to drunkenness to an excessive degree. The population of the colony is estimated at about 12,000.

The present constitution of Honduras is based upon an act passed in 1853. By this act the legislature consists of the superintendent and a legislative assembly of twenty-one members, eighteen of whom are elected, and three appointed by the government. Members are required to be of full age, of native birth, or naturalized, and in the possession of personal property within the settlement to the amount of L.400. Electors must be owners or occupiers of real property to the amount of L.7 per annum. The assembly lasts for four years, subject to prorogation or dissolution. The superintendent has also the assistance of an executive council of six members, three of whom are designated official, and three are appointed by the superintendent, with the approbation of the crown. The superintendent of Honduras is under the control of the governor of Jamaica, from whom he receives his commission. In religious matters, too, Honduras forms part of the bishopric of Jamaica. There are two parish churches in Belize, a free Scotch church, and chapels for Wesleyans and Baptists. There is also a grammar school, founded in 1846, and having, in 1847, 175 pupils. Petty larceny and misdemeanours resulting from intemperance frequently occur, but atrocious crimes are happily seldom perpetrated. In the mechanical arts the blacks display little or no ingenuity, but the coloured people are considerably above the negroes in this respect.

The exports consist chiefly of mahogany, logwood, rosewood, hides, tortoise-shell, fustic, cochineal, indigo, sarsaparilla, and cocoa-nuts; the imports chiefly of manufactured goods from Britain. Much of the exports are brought hither from the neighbouring states in small coasters. The total value of exports in 1851 was L.411,443; in 1852, L.399,223; in 1853, L.345,377; and in 1854, L.452,313. The imports in 1854 amounted to L.2,417,642. (Martin's *British Colonies, Parliamentary Reports*, &c.; Capt. Henderson's *Honduras.*)

Honduras, one of the republican states of Central America, lying between W. Long. 83. 20. and 89. 30., and N. Lat. 13. 10. and 16.; and bounded on the N. and N.E. by the Bay of Honduras and the Caribbean Sea, S.E. by Nicaragua, S. by the Gulf of Fonseca and San Salvador, and W. by Guatemala. On the N. it has a coast-line of about 400 miles from the mouth of the Rio Tinto, in W. Long. 88. 30., to Cape Gracias á Dios, at the mouth of the Rio Wanks or Segovia, in Long. 83. 11. The boundary line follows the Wanks for about two-thirds of its length, and thence deflects in a south-westerly direction to the sources of the Rio Negro, which there forms its boundary to the Gulf of Fonseca, along which it has a coast-line of about 60 miles, to the mouth of the Rio Goascoran. It follows the course of that river, due N., for about 30 miles to the mouth of one of its affluents from the N.W., called Rio Pescado. From the head of this stream it strikes a branch of the Rio Torola, along which it continues to the mouth of the latter, in the Rio Lempa. The Lempa, and subsequently its affluent the Rio Lumpul, constitute its boundary to a point near the source of the latter, where its waters approach those of the Rio Paza. From this point it runs nearly N.E., along the mountain chain of Merendon and Grita to the head waters of the Rio Tinto.

The general aspect of Honduras is mountainous. Ranges of mountains and hills radiate towards the N. and E. from the common base of the Cordilleras. This great chain does not in Honduras approach within 50 or 60 miles of the Pacific, and on that side presents the general appearance of a great natural wall. A lower range of mountains, relieved by volcanic peaks of wonderful regularity of outline, intervenes between it and the ocean. It seems as if the waters of the Pacific had at one time washed the foot of this great mountain barrier, and the now intervening coast range had resulted from subsequent volcanic forces. The great chain of the Cordilleras does not throughout maintain its general character of an unbroken range, but occasionally forms interior basins or valleys, within which are collected the head waters of the large streams that traverse the country in the direction of the Atlantic. The northern and eastern coast of Honduras presents several bold groups of mountains, the terminations of ranges radiating from the Cordilleras. From the high plateaux of Guatemala the great range of the Cordilleras pursues a nearly eastern course to the frontier of Honduras, where it is deflected to the S.E., while a higher range, not inferior in height to the main chain, runs off E. by N. to the Bay of Honduras. At the point of separation this range is called the mountains of Merendon, afterwards Grita, and nearer the coast, Espiritu Santo. On the coast, where it attains the great height of 7000 or 8000 feet, it takes the name of Omoa. The main chain, at the distance of a few leagues from the mountains of Merendon, forms a mass or group known as the mountains of Selaque; and intermediately lies the great valley or plain of Sensenti, which is about 30 miles in length by from 10 to 20 in breadth. It is almost wholly enclosed by mountains, the only outlet being the narrow valley or gorge through which flows the Rio Higuito or Talgua, subsequently the Rio Santiago. The mountains of Selaque constitute one of the principal centres of elevation in Honduras, rising to the height of 8000 or 10,000 feet. The Rio Mejicote or Rio Grande de Gracias, a branch of the Santiago, separates them on the E. from the mountains of Paca with their lofty peak, and from the terraced mountains of Opalaca or Intibucat with their truncated summits and elevated plains. The valley of the Rio Sta Barbara, one of the principal affluents of the Santiago, intervenes between the mountains of Opalaca and the group of the Montecillos. This group is formed by the true range of the Cordilleras, which turns abruptly from its previous course, E. by S., to a direction due N., and finally loses itself in diverging ranges toward the coast. The divergences form another mountain-bound valley, in the centre of which lies the Lake of Yojoa. At the eastern base of the Montecillos range, where the interruption of the Cordilleras is complete, lies the plain of Comayagua, about 1900 feet above the sea, from which, extending due N. to the Atlantic, is the valley of the Rio Humuya, and due S. to the Pacific is the valley of the Rio Goascoran—thus constituting a great transverse valley reaching from sea to sea. The plain of Comayagua is probably about 40 miles in length from N. to S., with a general width of from 5 to 15 miles. It slopes almost imperceptibly toward the N., where a range of low hills separate it from the plain of Espino. These two plains, both of great beauty and fertility, occupy nearly one-third of the distance between the Bay of Honduras and that of Fonseca. Beyond the plain of Comayagua the Cordilleras again form a great group or mass of high mountains, the northern part being known as the mountains of Comayagua, the southern as the mountains of Lepaterique. They extend about 80 miles from N. to S., and near the centre send off a high range known as the mountains of Ule. Nearly to the westward of the mountains of Comayagua, and separated from them by the valley and river of the Sulaco, is the Sulaco group, standing almost in the centre of the state, and forming the nucleus of several extensive ranges little inferior to itself in elevation. That which extends to the N.E. is called the mountains of Misoco; that to the N. the mountains of Pija, terminating its numerous spurs in the high peaks of Congrehoy, which frown over the Bay of Honduras; while that called the mountains of Chili pursues a tortuous south-western course, and finally skirts the northern border of the transverse valley of the Nicaraguan lakes. At the base, and to the E. and N.E. of the mountains of Sulaco, are the broad and elevated plains or terraces of the Olancho and Yoro, celebrated for the number and excellence of their cattle. Most of that wide region between the Sulaco mountains and the Atlantic, comprising nearly one-half of the territory of the state, is uninhabited except by detached Indian tribes, and is but little known, except that it is very diversified and rich in the nature of its soil and the variety of its minerals. The northern coast of Honduras presents a diversified surface. A portion is flat, and covered with vast growths of timber. In other places the mountains extend to or very near the coast. Those of Omoa overshadow the Bay of Amatique, and those of Congrehoy and Poyos form conspicuous landmarks from the ocean, which breaks almost at their feet. Honduras thus presents the greatest diversity of surface; fertile valleys, wide and elevated plains, and mountains terraced to their summits, affording almost every variety of soil, climate, and production.

The rivers of Honduras are numerous, and some of them of great size. The principal are the Chamelicon, Ulua, Aguan or Roman, Tinto or Black River, Patuca, and Wanks or Segovia, flowing into the Atlantic; and the Choluteca, Nacaome, and Goascoran, flowing into the Bay of Fonseca. The Chamelicon rises in the mountains of Merendon, and pursues a generally N.E. course to the Atlantic. It is of great length and rapid, but as it drains only a small section of country, its body of water is small. The Ulua, on the other hand, drains a vast expanse of territory, comprehending nearly one-third of the entire state, and is the largest river in Central America, the Wanks perhaps excepted. The principal tributaries are the Santiago, Sta Barbara, Blanco, Humuya, and Sulaco. It has a bar at the mouth with only 9 feet of water, but steamers of light draught may ascend to the mouth of the Humuya. The Rio Aguan or Roman River is a large stream rising in the mountains of Sulaco, and falling into the sea a little to the E. of Truxillo, after a course of about 120 miles. The Rio Tinto or Black River, which at a short distance from the coast takes the name of Poyer or Poyas, is a considerable stream, said to have a course of about 120 miles. The Patook or Patuca River is the largest on this coast, between the Ulua and the Wanks. It takes its rise in the department of Olancho, in the vicinity of the town of Juticalpa. The principal streams which unite to form the Patuca are the Jalan, Tinto de Olancho, Guyape, and Guallambre. The principal mouth of the Patuca is obstructed by a shifting bar, on which there is generally from 8 to 10 feet of water. An arm of the Patuca, called Toomtoom Creek, diverging from the main stream at a short distance from its mouth, connects it with Brus or Brewer's Lagoon, which communicates with the sea by a wide mouth, but only accessible to vessels of six or seven feet draught. Eastward from the mouth of the Patuca is the Carataska or Cartago Lagoon, about 36 miles in length by about 12 in breadth, and varying in depth from 6 to 12 or 18 feet. The Rio Wanks or Segovia is certainly the longest if not also the largest river in Central America. It rises in the department of Nueva Segovia, in the extreme N.W. corner of Nicaragua, within 50 miles of the Bay of Fonseca, and flows N.E. into the Caribbean Sea at Cape Gracias á Dios. Its length is estimated at not less than 350 miles. The three principal rivers flowing into the Pacific are the Goascoran, Nacaome, and Choluteca, of which the last named is the largest. It rises in the Lepaterique Mountains, at the head of the plain of Comayagua, flows eastward until it reaches the meridian of Tegucigalpa, then turns abruptly N., passes that city, and after describing a circuitous route, runs nearly S. into the Gulf of Fonseca, having a total length of 150 miles. The Rio Nacaome collects its waters on the S. side of the Lepaterique Mountains, while the Choluteca drains their northern slope. It is not a long stream, but is very rapid, and carries along a considerable body of water. The River Goascoran rises among the low hills which lie at the head of the great plain of Comayagua, and has a course due S. of 70 or 80 miles. During the rainy season it is of considerable size, but in the dry season it is fordable without difficulty at any point. The only lake of importance is that of Yojoa or Taulebé. It is closely shut in by mountains, and is probably about 25 miles in length, by from 3 to 8 in breadth. The River Blanco, a narrow but deep stream, flows from its northern extremity into the Ulua. The Bay of Fonseca, the greater portion of which belongs to Honduras, is upwards of 50 miles in length, by about 30 in average breadth, with an entrance 18 miles wide, between the volcanoes of Conchagua (3800 feet in height) and Coseguina (3000 feet in height). Across this entrance lie the two islands of Conchaguita and Mianguera, and a collection of high rocks called *Los Farellones*, forming four distinct channels, each having sufficient depth of water to admit the largest vessels. On the island of Tigre, near the centre of the bay, is the free port of Amapala, belonging to Honduras. The largest island in the bay is the Sacate Grande, 7 miles in length, by 4 in breadth, and of great fertility, in some parts densely wooded with cedar, mahogany, and other valuable trees; in others covered with luxuriant pasture.

The principal ports of Honduras on the Atlantic are Puerto Caballo, Omoa, and Truxillo. Puerto Caballo, the first port established by the Spaniards on the northern coast, is in N. Lat. 15. 49, W. Long. 87. 57. Cortez, in his expedition into Honduras, founded a settlement here for the purpose of making it the grand entrepôt of New Spain. For upwards of two centuries it was the principal establishment on the coast; but during the time of the buccaneers it was removed to Omoa, because of the large size of the bay, which could not be properly defended. This bay is not less than 9 miles in circumference, of ample depth—two-thirds of it being from 6 to 12 fathoms—and has secure holding ground. It is perfectly protected from the N.N.E. and N.W. winds, which are those that prevail on this coast. The port of Omoa, in N. Lat. 15. 47., W. Long. 88. 3., is small but secure, and is defended by a strong fort, called El Castillo de San Fernando. The anchorage is good, in from 2 to 6 fathoms. The town stands about a quarter of a mile from the shore, and contains about 2000 inhabitants. Truxillo is situated on the western shore of a noble bay, in N. Lat. 15. 55., W. Long. 86. Young estimated the population in 1842 at 2500, of whom 1000 were whites and Ladinos, and 1500 Caribs. The latter are described as tall, athletic, hardy, and industrious.

The coast alluvions of Honduras are generally densely wooded, the elevated valleys of the interior spread out in broad savannahs, and the mountain plateaux are covered with forests of scattered pines, relieved by occasional clumps of oak. Upon the northern coast, in the broad plain through which the Ulua and Chamelicon flow, the country is so low as to be occasionally overflowed for considerable distances. Here grow immense forests of cedar, mahogany, caiba, India-rubber, and other large and valuable trees, thickly interspersed with palms. Farther to the eastward on the same coast the heavy forests are confined chiefly to the river valleys, and give place at short distances inland to sandy savannahs, covered with coarse grass and clumps of pines and acacias. The alluvions of the Pacific coast are also densely wooded, but not extensive. At short distances inland they give place to numerous savannahs, studded with clumps of acacias, and covered with grass; but the pine does not appear here except upon the slopes of the hills at an altitude of about 1200 feet. The valleys of the rivers on both coasts are thickly wooded; but as they ascend towards the interior, vegetation diminishes, and is reduced to a narrow fringe of trees and bushes upon their immediate banks. These valleys in the high interior country often expand into broad and beautiful plains—half savannah, half woodland—where the palm and the pine flourish side by side. The mountains which rise around these valleys are ascended by terraces crowned with forests of pines and oaks, and covered with grass. The summits of the mountains sometimes rise in peaks, but generally constitute broad table-lands, more or less undulating, and often spreading out in savannahs, traversed with long ridges of verdure and green belts of trees.

Of the vegetable productions of Honduras the mahogany tree stands first in importance, and, from its vast size and magnificent foliage, is deservedly entitled "king of the forest." It is to be found in nearly all parts of Honduras, in the valleys of the various streams. It is, however, most abundant upon the lower valleys of the rivers flowing into the Bay of Honduras, where the *cortes* (cuttings) are chiefly carried on by the Spaniards. A fixed sum is paid to the government for each tree cut down. Rosewood is common on the northern coast, where it is beginning to form an article of commerce. Lignum vitæ abounds in the valley of the Ulua, on the river banks in the plain of Comayagua, and in other parts. Among the numerous dyewoods for which Honduras is celebrated, may be mentioned fustic, Brazil wood, yellow sanders, dragon's-blood tree, Nicaragua wood (a variety of Brazil wood), and the anotta. Among the gum and medicinal trees, are the gum-arabic tree, copaiba tree, copal tree, liquid amber, castor oil, ipecacuanha, and the *Hevea elastica*. Among the more common of the others are the long-leaved or pitch pine, cedar, *ceiba* or silk-cotton tree, live oak, mangrove, iron-wood, calabash, various kinds of oak and palm, lime, lemon, orange, cocoa, pimento, citron, tamarind, and guava. Sarsaparilla is obtained in great abundance, and of superior quality. The sugar-cane grows luxuriantly on the plains and among the mountains, at elevations of 3000 to 4000 feet. Coffee, indigo, tobacco, maize, wheat, rice, and potatoes are also grown.

The domestic animals are the horse, ass, ox, sheep, goat, hog, dog, and cat. The wild animals comprise the deer, tapir, racoon, opossum, squirrel, ant-eater, armadillo, and various species of monkey; also the jaguar, black tiger, tiger-cat, and the cougar. Numerous varieties of parrot abound everywhere; and the macaw and toucan are common on both coasts. Among the birds of prey are hawks, vultures, owls, and sea-eagles. The crow, blackbird, Mexican jay, rice-bird, swallow, rain-bird, and numerous varieties of humming-bird are common. Of water birds the pelican, Muscovy duck, black duck, curlew, plover, spoonbill, teal, darter, heron, ibis, and crane, are abundant on the banks of the lagoons and rivers. The *Crax alector*, *Crax rubra*, *Pauxi galeata*, Guan, Mexican partridge, quail, snipe, and several varieties of wood-pigeon are most numerous in the interior. Alligators are common in the lagoons and rivers of both coasts. Of the lizard tribe there are numerous varieties; the most remarkable is the iguana. Serpents of several kinds are common on the coasts, but they are mostly harmless. The tortoise and turtle are numerous, and of several kinds.

Honduras, in point of mineral resources, ranks first among the states of Central America. Silver, the most abundant and valuable of the ores existing in the state, is found in various combinations—with iron, lead, copper, and in some instances with antimony. Chlorides of silver are not uncommon. The silver ores are chiefly found upon the Pacific ranges or groups of mountains, while the gold washings, if not the gold mines proper, are most numerous on the Atlantic slope. The mineral district of Yuscuran, in the department Tegucigalpa, is noted for the number and value of its mines. The ores are for the most part an argentiferous galena yielding from 63 to 1410 oz. per ton. The mines throughout this department and that of Choluntica yield a similar ore, generally occurring in a matrix of quartz with varying proportions of brown blende, and sulphurets of zinc and iron, and oxides of iron. The mines of the department of Gracias are equally celebrated with those of Tegucigalpa. Gold mines are not uncommon in Honduras; but, with the exception of those of San Andres in the department of Gracias, and those in the vicinity of San Juan Cantaranas in Tegucigalpa, they are no longer worked. The principal supplies of this metal are drawn from the gold-washings of Olancho, which are exceedingly productive. The River Guyape has always enjoyed great celebrity for the amount of gold contained in its sands; but since the early period of Spanish occupancy washing has not been carried on, except on a very small scale by the Indians, and even with them the process is generally left to the women and children. There are also very valuable mines of copper; the ores containing also considerable proportions of silver. Those of Coloal in Gracias contain about 58 per cent. of copper, besides about 80 oz. of silver to the ton. The mine of Guanacaste, in Olancho, gives upwards of 80 per cent. of pure copper, besides about 2·9 per cent. of silver. Iron-ore is common, but no mines of it are worked except those of Agalteca in Tegucigalpa. Platina is said to exist in the departments of Choluteca and Gracias; but the mines have never been worked. Cinnabar has also been found in several places, but probably not in sufficient quantities to admit of being reduced with profit. Zinc, antimony, and tin also exist. The opal mines of Gracias are worked to a large extent, and have been very productive; and beds of coal have been discovered in several localities. An abundance of fine white, blue, and veined limestone is scattered throughout every department of the state; while the hills and mountains at the back of Omoa have exhaustless quarries of a fine compact white marble, well adapted for statuary and ornamental use.

The N. and E. coast of Honduras has unquestionably a higher temperature than any other portion of the state. It diminishes, however, rapidly as we proceed inland, the modifying influence of the neighbouring mountains being felt even before the increase of altitude becomes perceptible. The table-lands have of course a climate varying with their elevation and their exposure to the prevailing winds. The climate at the mouth of the Rio Tinto, or Black River, in N. Lat. 16., W. Long. 85., is said to be pretty equable, varying only throughout the year from 62° to 86° Fahr. The heats are tempered during the greater part of the year by the grateful sea-breeze, and sometimes by the invigorating dry N. wind.

Honduras has an area of 39,600 square miles, and its population in 1855 was estimated at 350,000, exclusive of the Indian tribes. It is divided into seven departments as follows:—

Departments.	Estimated pop. in 1855.
Comayagua	70,000
Tegucigalpa	60,000
Choluteca	50,000
Santa Barbara	50,000
Gracias	55,000
Yoro	20,000
Olancho	45,000
	350,000

The department of Comayagua occupies the centre of the state. Tegucigalpa, the smallest and most populous, may be described as occupying a great interior basin or plateau, bounded on the N. and W. by the mountains of Sulaco and Comayagua, and on the S. and E. by those of Ule and Chili. Choluteca occupies the extreme S. fronting on the Bay of Fonseca. Santa Barbara lies northward of Gracias and Comayagua, between these departments and the Bay of Honduras. Gracias lies in the N.E. angle of the state touching upon Guatemala and San Salvador. Yoro comprehends all the northern portion lying E. of Ulua. Olancho lies immediately E. of Tegucigalpa.

The Indian or aboriginal population predominates in Honduras, as in Central America generally. In the eastern portion of the state, within the district which lies between the Rio Roman and the Segovia River, an area of not less than 15,000 square miles, the country is almost exclusively occupied by native tribes, known under the general names of Xicaques and Payas. Portions of these tribes have accepted the Catholic religion, and live in good understanding with the white population. The large town of Catacamas, and some others of less note in the vicinity of Juticalpa, in Olancho, are exclusively inhabited by Christianized Payas and Xicaque Indians. Apart from these, there are considerable numbers who live among the mountains, and who follow more closely their original modes of life, but who are also friendly in their intercourse with the Spaniards. They tacitly recognize the authority of the government, but it does not interfere with their modes of life. The names Xicaques and Payas may be regarded as general designations. The *Toacas* or *Towkas*, some of whom live on the banks of the Rio Patuca, and the *Secos*, found on the Rio Tinto or Black River, probably belong to the Payas. They are described by Young as having "long black hair hanging over their shoulders, very broad faces, small eyes, with a peculiar expression of sadness and docility, which prepossesses the beholder in their favour." "They are short, but remarkably strong, and capable of carrying heavy burdens over the rocky passes of their steep mountains without appearing to suffer much fatigue. Their character for faith and honesty stands high." The coast around Carataska Lagoon, and westward as far as Brewer's Lagoon, was for many years occupied by Sambos or Mosquitos, a mixed race of Negroes and Indians; but the Caribs spreading rapidly eastward from Truxillo and Black River, have now nearly displaced them, and driven them to the southward of Cape Gracias á Dios into the Mosquito territory. The Caribs are peaceable, active, and industrious, and are much employed by the mahogany cutters on the coast. The government of Honduras is popular and representative, all power emanating from the people, and all public functionaries being held responsible to the people for the faithful discharge of their duties. The executive power is vested in a president, who must be thirty-two years of age, a native of Central America, a citizen of the state for five years, and proprietor of real estate to the value of L.1000. He holds office for four years, and is incapable of being elected to serve for two consecutive terms. The legislative body is composed of fourteen deputies, half of whom retire annually. A deputy must be twenty-five years of age, a citizen of the department which he represents, and a proprietor to the value of L.100, or in the exercise of a profession or art yielding that annual return. The senators, seven in number, must be thirty years of age, proprietors each to the value of L.200, or licentiates in some of the liberal professions. The legislature imposes taxes; nominates, in joint session, the magistrates of the supreme court of justice; grants the annual appropriations; fixes the military contingent; controls the educational system; makes war or peace; ratifies treaties; and has the power of impeaching and trying the executive officers of the state. The supreme court of justice is divided into two sections of three members each, one of which is established in the city of Comayagua, and the other in that of Tegucigalpa. They must be advocates of established reputation, of at least twenty-five years of age, and proprietors to the value of L.200. Each department is presided over by a chief officer, named by the executive, who must be twenty-five years of age, and a proprietor in the department over which he is appointed. All persons born in the state, or in any of the other states of Central America, and resident in Honduras, are recognized as citizens; and foreigners may acquire the rights of citizenship by legislative act. The right of suffrage belongs to all citizens above twenty-one years of age, "but after 1870 it shall be limited to such only as may then be able to read and write." The press is free; and capital punishment is abolished. The established religion is Roman Catholic. There are two universities, one at Comayagua, the other at Tegucigalpa, with professorships of law, medicine, and theology.

Comayagua, formerly Valladolid, the capital of the state, is situated on the southern border of the plain of the same name, in N. Lat. 14. 28., W. Long. 87. 39. It was founded by Alonzo Caceres in 1540. In 1827 it was taken and burned by the monarchical faction of Guatemala. It then contained about 18,000 inhabitants, and was embellished with fountains and monuments; but has never since wholly recovered. It is the seat of a bishopric, and has a large and elegant cathedral, and a university. The trade of the city is small. Pop. about 8000. Tegucigalpa, the largest and finest city in the state, stands on the right bank of the Rio Choluteca, which is here crossed by a fine stone bridge of ten arches, connecting the town with the suburb of Comayaguita. The town is substantially and regularly built, and contains six large churches, one of which is scarcely inferior in size to the cathedral of Comayagua. Its trade was formerly chiefly carried on through Omoa and Truxillo, but since the establishment of the free port of Amapala, it has taken that direction. Pop. about 12,000.

The coast of Honduras was discovered by Columbus in 1502. It subsequently formed part of the Spanish kingdom of Guatemala, which comprised the provinces of Guatemala, Honduras, San Salvador, Nicaragua, and Costa Rica. These threw off their allegiance to Spain in 1821, and assuming the rank of sovereign states soon after united in a confederacy called the "Republic of Central America." This union, in consequence of internal dissensions, became practically dissolved in 1839, and since that time Honduras has continued to be an independent republic. (See *Notes on Central America*, by E. G. Squier. New York, 1855.) An American work having been chiefly followed in the preparation of this article, it is necessary to explain that a considerable portion of country described under Honduras is claimed by the English for the king of Mosquito; but otherwise the work quoted is the principal authority on the subject.

HONE, or Hone-Slate. These are various slaty-stones wrought into the form of straight slabs, and used for whetting or sharpening the edges of tools after they have been ground. They consist chiefly of the following:—1. *Norway rag-stone*, the coarsest variety of the hone-slates; it gives a finer edge than the sandstones. 2. *Charnley Forest stone*, which is used as a substitute for Turkey oil-stone. 3. *Ayr stone*, *Scotch stone*, or *slate stone*, used for polishing marble, and copper plates, but the harder kinds for whetstones. 4. *Idwall*, or *Welsh oil-stone*, used for small articles of cutlery. 5. *Devonshire oil-stone*, for sharpening thin-edged broad tools. 6. *Cutlers' green-stone*, from Snowdon, which is very hard and close, and is used for giving the last edge to lancets, &c. 7. *German razor-hone*, used almost entirely for razors. It is obtained from the slate mountains near Ratisbon, where it forms a yellow vein in the blue slate. It is sawn into thin slabs, and cemented to a slab of slate which serves as a support. 8. *Blue polishing stone*, a dark slate of uniform texture, used by workers in silver and some other metals, for polishing off the work. 9. *Gray polishing-stone*, somewhat coarser than the blue. 10. *Welsh clearing-stone*, a soft variety of hone-slate used by curriers for giving a fine edge to their broad knives. 11. *Peruvian hone*, for sharpening large tools. 12. *Arkanzas stone*, from North America. 13. *Bohemian stones*—used by jewellers.

Turkey oil-stone is superior to every other substance as a whetstone; it will abrade the hardest steel, and is sufficiently compact to resist the pressure required for sharpening a graver. The black variety is somewhat harder than the white. These stones are imported from Turkey in irregular masses, seldom exceeding three inches square, and ten inches long, and are cut up by means of the lapidary's splitting-mill, and diamond powder, then rubbed smooth with sand or emery on an iron plate, inlaid in wood, and secured by glazier's putty. Sperm or neat's foot oil, or some oil which does not readily thicken, should be used with them. Oil-stone powder is used for grinding together the brass or gun-metal fittings of mathematical instruments, and also instead of pumice-stone for polishing superior brass-work.

The following analyses throw an interesting light on the nature of polishing stones:—

	Alumina.	Silica.	Lime.	Iron.	Water.	Magnesia.	Carbonic Acid.
Polishing slate	4·0	83·5	8·5	1·6	9·0	...	...
Do. do.	7·0	66·5	1·25	2·5	19·0	1·5	...
Bohemian stone	1·0	79·0	1·0	4·0	14·0	...	...
Turkey hone...	3·33	72·0	13·33	...	...	...	10·33

(C. T.)

HONE, William, the author of the *Year Book*, *Every-Day Book*, &c., was the son of a dissenting minister of Bath, where he was born in 1780. Abandoning the law, to which he was originally trained, he began business as a bookseller and publisher, and acquired a great name by his vindication of popular rights in a newspaper which he edited under the title of the *Reformist Register*. His popularity was greatly extended by his famous series of political satires called *The Political House that Jack built*, which ran through upwards of fifty editions, and contributed greatly to bring into disrepute the government of the day. Encouraged by his success, he next published a series of parodies of the liturgy, also directed against the ruling powers, who determined to prosecute him for blasphemy. His defence, which lasted for three days, was conducted by himself with a courage, temper, and ability that recalled the days of Horne Tooke, and resulted in a triumphant acquittal. His subsequent publications of the *Every-Day Book*, &c., forming a kind of calendar of popular English amusements, sports, pastimes, ceremonies, manners, customs, and events incident to every day in the year, though they rendered good service to an important department of literature, involved him in debt, and at last landed him in jail, where he remained for some time. Released by the kindness of some friends, he opened the Grasshopper Coffee-house; and to eke out his scanty means, published his *Year-Book*, which was equally unfortunate with its predecessor. Towards the close of his life a complete change took place in his religious views; and from having been a scoffer, and as nearly an atheist as a man can be, he became a humble and anxious Christian. One result of this change was his appointment to the sub-editorship of the *Patriot* newspaper, which office he held till his death in 1842. After his death his collection of pamphlets, believed to be the best private collection then extant in England, was sold and dispersed. An interesting account of his conversion was published in London in 1853.

HONFLEUR, a seaport-town of France, department of Calvados, and arrondissement of Port l'Evêque, on the southern shore of the estuary of the Seine, 8 miles S.E. of Havre, with which it has regular steam communication. The town is old and ill built. The harbour is accessible only at high water, and is chiefly frequented by fishing or small coasting craft. The herring, mackerel, and whiting fisheries are actively prosecuted; and numerous vessels sail annually for the cod, whale, and seal fisheries. Honfleur sends weekly to England about 7000 dozens of eggs, besides butter, fruit, &c. Its commerce, formerly considerable, has been almost entirely absorbed by Havre. The chief manufactures are hosiery, lace, chemical products, and hardware. There are also shipbuilding yards, ropewalks, and saw-mills. The chapel of Notre Dame de Grace, on the hill above the town, is much frequented by sailors, and filled with their votive offerings. Pop. 9580.

HONG KONG, a small island, now a British colony, lying off the coast of China, at the mouth of the Canton River, about 40 miles E. of Macao, in N. Lat. 22. 16. 30, E. Long. 114. 14. 45. It is about 9 miles in length by 8 in breadth, and is separated from the mainland by a narrow strait varying from less than a mile to 4 or 5 miles in width. The appearance of the island is barren and unprepossessing. It consists for the most part of ranges of rocky hills, rising sometimes to the height of 1700 or 1800 feet above the sea. The highest peak is 1825 feet in height. There are no trees of any size on the island, and few valleys of any extent. The rocks of Hong Kong consist of granite intermixed with quartz, mica, and felspar, affording excellent materials for building. Among the vegetable productions of the island are mango, lichee, longan, orange, pear, rice, sweet potatoes, and yams. A small quantity of flax is grown, and prepared for household uses by the villagers. Since the occupation of the island by the English the potato of Europe and the fruits of Canton and Macao have been introduced, and lately many European seeds have been sent out. The land tortoise, a few small deer, and armadillos, and several kinds of snakes, are found on the island.

The climate of Hong Kong, like that of Macao, is not generally unhealthy, though from the numerous deaths that occurred in 1842 and 1843, this was supposed to be the case. Subsequent years, however, have shown that the climate here is no more prejudicial to health than that of any of our other eastern tropical possessions.

Hong Kong was first ceded to Britain in January 1841, and again by the treaty of Nanking in August 1842. The government is administered by a governor, aided by an executive council of three members, including the commander of the troops. There is also a legislative council, presided over by the governor. The government offices are at Victoria. The following table exhibits the progress of Hong Kong from 1848 to 1853, inclusive:—

	Pop. exclusive of Troops.	Revenue.	Parliamentary Grant.	Expenditure.
1848	21,514	L.25,091	L.25,000	L.62,658
1849	29,507	23,617	25,000	38,286
1850	33,292	23,526	20,000	34,314
1851	32,983	23,721	15,500	34,115
1852	37,058	21,331	12,000	34,765
1853	39,017	24,700	9,200	36,418

With reference to these six years the governor remarks "that the call on the home government for parliamentary grant has been reduced from L.25,000 to L.8500 (L.9200?) for the current year; that the expenditure has been reduced from L.62,658 to L.36,418; that the number of square-rigged vessels frequenting the port has increased from 700 to 1103, while their tonnage is nearly double; and that the population has in like manner advanced 82 per cent. during the past six years. In conclusion, I have no hesitation in saying that were this colony taxed in the same way as are the settlements in the straits under the government of the East India Company, it could in a year or two be made to pay its own expenses without the efficiency of the government being impaired."

In 1844 the total population (consisting of Chinese) was 19,463; while on 31st December 1853, the Chinese population was 37,536; Europeans and Americans, 476; other races, 1005. In 1853, 1103 square-rigged vessels, carrying in all 447,053 tons, arrived in Victoria harbour. Of these vessels 201 imported, and 154 exported goods into and from the colony, being an increase over 1852 of 74 and 79 vessels respectively; while the total tonnage of vessels arrived as compared with the preceding year shows an increase of 13,670 tons.

HONITON, a municipal and parliamentary borough and market-town of England, county of Devon, near the left bank of the Otter, 16 miles N.E. of Exeter. It consists of one wide and well-paved street, along which runs a small stream, supplying the town with water. The houses have generally a neat and respectable appearance, having been mostly built since the destructive fires of 1745 and 1765. The parish church, about half-a-mile from the town, was built by Courtenay, Bishop of Exeter, about 1482, and is remarkable for a curiously carved screen. A modern Gothic church stands in the centre of the town. It has a free grammar school, national school, hospital, and several charities. The serge manufacture was formerly extensively carried on here, but now its chief manufacture is "Honiton lace." Honiton is governed by a port-reeve, and returns two members to parliament. Pop. (1851) 3427.

HONOLULU, or Honoruru, the principal town of the Sandwich Islands, and the residence of the king, is situated on the S. side of the island of Woahoo, in N. Lat. 21. 18. 12., W. Long. 157. 55. It forms an entrepôt for European and Indian goods, whence they are re-shipped to America. It is also a general rendezvous of whaling vessels,—and sometimes 80 sail of them, each from 300 to 500 tons, are at anchor here together. In 1851, 446 merchant ships arrived at the port; in 1852, 235; and in 1853, 194. The imports in 1853 amounted to L.256,400, and the exports to L.56,320. Pop. about 7000.

HONORIUS, Flavius, son of Theodosius the Great, was born, probably at Constantinople, A.D. 384. His elder brother Arcadius was Emperor of the East, and in A.D. 395 Honorius himself came into possession of the West. Being only in his eleventh year, Stilicho, an able and ambitious general, was made guardian to the young prince. He fought the battles of the empire against the countless hordes of barbarians who now poured down from the north. In A.D. 398 Stilicho's daughter Maria was married to Honorius, but they were both mere children. The close of the century was marked by the efforts to destroy paganism within the empire. All temples, altars, and property of any kind, used in the service of paganism were ordered to be demolished. During the first years of the fifth century Stilicho was occupied in driving back the hordes of Alaric. The latter was routed on the Tanaro, and driven across the Alps. About A.D. 404 the cruel exhibitions of gladiators were suppressed in Rome. The frequent ravages committed by the Goths, Huns, Alans, and other tribes, induced Honorius to change the seat of government from Milan to the strong fortress of Ravenna. He had scarcely done so when Rhadagaisus appeared in Italy with several hundred thousand barbarians, ravaging all before them. They were ably met, however, and defeated by Stilicho at Fesulæ. Gaul was next ravaged by the barbarians, including Vandals, Sueves, and Alans; and Stilicho is suspected of having been concerned in instigating them to this step. Meanwhile great confusion was created in Britain. The troops revolted, and appointed successively three emperors. The last of these, named Constantine, passed into Gaul, and defeated the forces sent against him. Honorius now became suspicious of Stilicho. The emperor wished to marry Thermantea, Stilicho's other daughter (Maria being dead), but Stilicho objected. Moreover the empire of the East had devolved upon a child, and it was thought that Stilicho wished to get the guardianship of the East as he had had of the West. He and several other officers were seized and put to death. Whether Stilicho cherished any traitorous designs or not, it is certain that his death was an irreparable loss to the empire. Alaric now came and besieged Rome itself, A.D. 408. In the following year he took it, and appointed Attalus emperor. Shortly after Rome was plundered by Alaric. Constantine, the usurper, having surrendered on condition of having his life spared, Honorius broke faith, and had him put to death. Ataulphus, the successor of Alaric, married Placidia, the sister of Honorius, and made a treaty with Honorius. After the death of Ataulphus, Placidia was married to Constantine, the colleague of Honorius in the consulship. Honorius was thirteen times consul. He died of dropsy, A.D. 423, in the twenty-ninth year of his reign, at the age of thirty-nine.

Honorius I., the successor of Boniface V. to the see of Rome, was born in Campania, raised to the pontificate in A.D. 626, and died A.D. 638. The beginning of his pontificate was marked by the disturbances of the Welsh clergy, who resisted both the pretensions of the Bishop of Rome, and the erection of Canterbury and York into archbishoprics. Honorius has been accused of inclining towards the heresy of the Monothelites. The justice of the allegation has been denied by Baronius and others. Still the opinion that Honorius held on the subject was pronounced heresy in the 6th Council of Constantinople, A.D. 680. The existing letters of Honorius to Sergius, the patriarch of Constantinople, indicate a leaning towards Monothelism—*i.e.*, the doctrine that our Lord had only a single will; yet Honorius was not disposed to press the question so as to raise discussion.

Honorius II. was born in the county of Bologna, and raised to the see of Rome A.D. 1124. He had been elected Bishop of Ostia by Pope Pascal. His name was Lambert de Fagnan. His elevation was opposed by the partizans of Tebald, who had been elected and invested with the pontifical robes. Tebald, however, withdrew when he saw a tumult arising. Honorius in effect, did the same, but was again invested by the cardinals. A dispute arose between Honorius and Roger Count of Sicily; and Robert Prince of Capua was induced by Honorius to oppose him, but Roger came off victorious. Honorius was no more successful in his interference with the Bishop of Paris. The bishop, wishing to introduce some reform, was opposed by the clergy and the king, Louis VI. The bishop put the royal lands under interdict. At first Honorius annulled the acts of the bishop; but owing to the powerful assistance of St Bernard, who supported the bishop, Honorius withdrew his opposition. He died A.D. 1130.

Honorius III., successor to Innocent III., was elected Pope A.D. 1216. His name was Cencio Savelli. He began at once to take part in the affairs of the East and the West. He assured the king of Jerusalem of his willingness to support the crusades. He wrote to the French bishops to kindle the ardour of the pilgrims, and promised the Emperor of the East his co-operation in subduing schism. He took part in the election of Peter of Courtenay, and crowned him Emperor of the West. Honorius was very anxious to organize a crusade to the Holy Land. Frederick II. was crowned for the express purpose of undertaking one, and promised, upon oath, to be ready in two years. But great difficulties were encountered, owing to the disturbed state of Europe. Spain and Portugal were devastated by the Moors, as well as by the wars of succession between the Houses of Castille and Leon. In the south of France there was already a crusade against the Albigenses; and differences existed between the House of Montfort and the Counts of Toulouse. Honorius died A.D. 1227, in the eleventh year of his pontificate, and without accomplishing anything important.

Honorius IV. succeeded Martin IV. in the Papal chair in A.D. 1285. His name was Giacomo Savelli. Having the gout both in his hands and feet, he is said to have required the help of instruments in celebrating mass. He induced Philippe-le-Hardi to wage war against Pedro of Aragon, who held Charles II. of Sicily in prison, but without succeeding. He died A.D. 1287.

HONOUR, Legion of, an order instituted (3d June 1802) by Napoleon I., when first consul, for civil and military merit. See France, § xiii.

HONOURABLE, a title conferred on the younger sons of earls, and on all the children of viscounts and barons. It is also conferred on persons holding certain situations of trust and dignity, such as the maids of honour to the Queen, &c., and to members of certain public bodies, as the House of Commons, East India Company, &c. The title of Right Honourable is given to all peers and peeresses of the United Kingdom; to the eldest sons and all the daughters of peers above the rank of viscount; to all privy councillors; and to various civic functionaries in the different capitals of the kingdom.

HOOD, Robin, a celebrated outlaw, who lived in the reign of Richard I., about the close of the twelfth and beginning of the thirteenth century. He dwelt principally in Sherwood Forest, in Nottinghamshire. At the period during which Robin Hood performed his exploits the forest laws were enforced with great rigour by the Norman kings; and, as a consequence, numbers fled to solitudes and natural strongholds. Having a common interest, they banded together; and by their acquaintance with unfrequented localities they were able to elude the vigilance of pursuers, as well as at times to present a bold front even to a numerous enemy. Stow mentions that Robin Hood had a hundred companions, able-bodied men, and skilful archers, who were so formidable that four hundred would not attack them. But Robin pursued a certain system in his robberies. He

Hood, Samuel.

spared the poor, and plundered the rich. Stow says, "He suffered no woman to be oppressed, violated, or otherwise molested. Poor men's goods he spared, *abundantly relieving them with that which by theft he got from abbeys and rich old carles.*" Hence it is not wonderful that Robin became a very great favourite with the lower classes of people. His exploits have been celebrated from early times in great numbers of popular ballads, setting forth his courage, strength, skill in deer-hunting, chivalry towards the fair sex, and humanity towards his poorer neighbours. The poems, songs, and ballads relating to him have been brought together in Ritson's *Robin Hood Collection*, 8vo, 1795, London. Not much can be gathered regarding Robin Hood's real history from these poems, many of them being written long after his time. He appears to have been a yeoman, though Ritson gives some credit to the epitaph at Kirklees in Yorkshire, which represented him as an earl of Huntingdon. As to the MS. in the *Sloane Collection*, which speaks of Robin as an earl, the question is at once raised regarding the antiquity and value of the MS., which probably belongs to a period long subsequent to Robin Hood. Of his companions Little John and Friar Tuck, his chaplain, were the most notable. Robin is said to have been bled to death by a nun, near Kirklees, A.D. 1247. See Ritson's *Robin Hood Collection*, and Percy's *Reliques of Ancient English Poetry.*

Hood, *Samuel*, better known as *Viscount Hood*, belonged to a family of which several members have earned a lasting name in the naval annals of England. He was born in 1724 at Butley, in Somersetshire, of which parish his father was rector. Entering the navy at an early age, he passed rapidly through the inferior grades, and in 1757 was made captain of the Antelope, a 50-gun ship, with which he captured a French ship of equal size. After serving in the Mediterranean and on the American coast with such distinction as to earn a baronetcy, he was sent in 1780 to the West Indies to co-operate with Sir George Rodney, and while there fought some indecisive actions with the Comte de Grasse. In the course of the American War he again engaged that commander off the mouth of the Chesapeak, and with a similar result. In the actions of the 9th and 12th April, which followed the capture of the island of St Christopher by the French, Hood had the brunt of the battle to bear, and distinguished himself so much that he was created a peer of Ireland with the title of Baron Hood of Catherington; and on Rodney's return home was promoted to the chief command, which he held till peace was proclaimed in 1783. When the war of the French Revolution broke out Hood was sent to the Mediterranean, where the royalists in Toulon received him with open arms, and surrendered that city to his care. When the republicans, under the command of Napoleon, were on the point of regaining possession of the city, Hood destroyed the arsenal, and burned fifteen sail of the line, besides carrying off eight; and in the following year signalized himself by expelling the French from Corsica. Soon after this exploit he returned home, and was rewarded for his numerous services with the governorship of Greenwich Hospital, an English peerage with the title of Viscount Hood of Whitley, and finally with the Grand Cross of the Bath. He was in his ninety-second year when he died at Bath, June 27, 1816. In Viscount Hood were combined the finest qualities of the English sailor. He certainly had not the genius of Blake or Nelson; but among the men of talent who have contributed to raise the British navy to its present pre-eminence, few stand higher than he. To great nautical skill he joined high courage, a prompt decision of movement, and a sagacity of judgment that won the confidence of the nation as well as of the fleet. With all his daring he was cautious enough to avoid risking his ships or men unless the prize were a very tempting one, or unless, with the means at his command, he felt himself justified in trying to secure it.—The career of Lord Hood's younger brother Alexander, afterwards Viscount Bridport, was very similar to his own. Passing rapidly through the lower grades of the service, he rose to be second in command of the fleet which was sent out in 1782 under Lord Howe to relieve Gibraltar. In that commander's great victory with the Channel fleet on June 1, 1794, Hood was again his second in command, and contributed greatly to the successful result of the action. In the following year, while enjoying an independent command, he encountered a French fleet off L'Orient, and took three sail of the line. When Lord Howe retired from the service Hood succeeded him in the command of the Channel fleet, which he retained till 1800. In 1801, his numerous and valuable services were rewarded with an English peerage under the title of Viscount Bridport. He died at Bath in 1814.—Hardly less distinguished than either of the above was their cousin Sir Samuel Hood, who earned his laurels at Toulon, Corsica, and the Nile. In 1806 he greatly signalized himself by the capture of three French frigates in an action off Rochefort, for which exploit he was rewarded with the Order of the Bath. Soon after the battle of Copenhagen, in which he took part, he was promoted to the highest naval command in India, where he died in 1814. To the remarkable nautical talents that seemed hereditary in the family to which he belonged, he superadded a great knowledge of science, of which he was an arduous student.

Hood, Thomas.

Hood, *Thomas*, humourist and poet, born 1789, the son of Mr Hood, bookseller, of the firm of Vernor and Hood, a man of intelligence, and the author of two novels. "Next to being a citizen of the world," writes Thomas Hood in his *Literary Reminiscences*, "it must be the best thing to be born a citizen of the world's greatest city." The best incident of his boyhood was his instruction by a schoolmaster who appreciated his talents, and, as he says, "made him feel it impossible not to take an interest in learning while he seemed so interested in teaching." Under the care of this "decayed dominie," whom he has so affectionately recorded, he earned a few guineas—his first literary fee—by revising for the press a new edition of *Paul and Virginia.* Admitted soon after into the counting-house of a friend of his family, he "turned his stool into a Pegasus on three legs, every foot, of course, being a dactyl or a spondee;" but the uncongenial profession affected his health, which was never strong, and he was transferred to the care of a relation at Dundee. He has graphically described his unconditional rejection by this inhospitable personage, and the circumstances under which he found himself in a strange town without an acquaintance, with the most sympathetic nature, anxious for intellectual and moral culture, but without guidance, instruction, or control. This self-dependence, however, suited the originality of his character: he became a large and indiscriminate reader, and before long contributed humorous and poetical articles to the provincial newspapers and magazines. As a proof of the seriousness with which he regarded the literary vocation, it may be mentioned that he used to write out his poems in printed characters, believing that that process best enabled him to understand his own peculiarities and faults, and probably unconscious that Coleridge had recommended some such method of criticism when he said he thought "print settles it."

His modest judgment of his own abilities, however, deterred him from literature as a profession, and on his return to London he applied himself assiduously to the art of engraving, in which he acquired a skill that in after years became a most valuable assistant to his literary labours, and enabled him to illustrate his various humours and fancies by a profusion of quaint devices, which not only repeated to the eye the impressions of the text, but, by suggesting amusing analogies and contrasts, added considerably to the sense and effect of the work.

In 1821 Mr John Scott, the editor of the *London Magazine*, was killed in a duel, and that periodical passed into the hands of some friends of Mr Hood, who proposed to him to take a part in its publication. His installation into this congenial post at once introduced him to the best literary society of the time; and in becoming the associate of such men as Charles Lamb, Cary, De Quincy, Allan Cunningham, Proctor, Talfourd, Hartley Coleridge, the peasant-poet Clare, and other contributors to that remarkable miscellany, he gradually developed his own intellectual powers, and enjoyed that happy intercourse with superior minds for which his cordial and genial character was so well adapted, and which he has described in his best manner in several chapters of *Hood's Own*. *Odes and Addresses*—his first work—were written about this time, in conjunction with his brother-in-law Mr J. H. Reynolds, the friend of Keats; and it is agreeable to find Sir Walter Scott acknowledging the gift of the work with no formal expressions of gratification, but "wishing the unknown author good health, good fortune, and whatever other good things can best support and encourage his lively vein of inoffensive and humorous satire." *Whims and Oddities*, *National Tales*, *Tylney Hall*, a novel, *The Plea of the Midsummer Fairies*, followed. In these works the humorous faculty not only predominated, but expressed itself with a freshness, originality and power, which the poetical element could not claim. There was much true poetry in the verse, and much sound sense and keen observation in the prose of these works; but the poetical feeling and lyrical facility of the one, and the more solid qualities of the other, seemed best employed when they were subservient to his rapid wit, and to the ingenious coruscations of his fancy. This impression was confirmed by the series of the *Comic Annual*, a kind of publication at that time popular, which Mr Hood undertook and continued, almost unassisted, for several years. Under that somewhat frivolous title he treated all the leading events of the day in a fine spirit of caricature, entirely free from grossness and vulgarity, without a trait of personal malice, and with an under-current of true sympathy and honest purpose that will preserve these papers, like the sketches of Hogarth, long after the events and manners they illustrate have passed from the minds of men. But just as the agreeable jester rose into the earnest satirist, one of the most striking peculiarities of his style became a more manifest defect. The attention of the reader was distracted, and his good taste annoyed, by the incessant play upon words, of which Hood had written in his own vindication,—

> "However critics may take offence,
> A double meaning has double sense."

Now it is true that the critic must be unconscious of some of the subtlest charms and nicest delicacies of language, and which would exclude from humorous writing all those impressions and surprises which depend on the use of the diverse sense of words. The history, indeed, of many a word lies hid in its equivocal uses; and it in no way derogates from the dignity of the highest poetry to gain strength and variety from the ingenious application of the same sounds to different senses, any more than from the contrivances of rhythm or the accompaniment of imitative sounds. But when this habit becomes the characteristic of any wit, it is impossible to prevent it from degenerating into occasional buffoonery, and from supplying a cheap and ready resource, whenever the true vein of humour becomes thin or rare. Artists have been known to have used the left hand in the hope of checking the fatal facility which practice had conferred on the right; and if Mr Hood had been able to place under some restraint the curious and complex machinery of words and syllables which his fancy was incessantly producing, his style would have been a great gainer, and much real earnestness of object, which now lies confused by the brilliant kaleidoscope of language, would have remained definite and clear. He was probably not unconscious of this danger; for, as he gained experience as a writer, his diction became more simple, and his ludicrous illustrations less frequent. In another annual called the *Gem* appeared the poem on the story of "Eugene Aram," which first manifested the full extent of that poetical vigour which seemed to advance just in proportion as his physical health declined. He started a magazine in his own name, for which he secured the assistance of many literary men of reputation and authority, but which was mainly sustained by his own intellectual activity. From a sick-bed, from which he never rose, he conducted this work with surprising energy, and there composed those poems, too few in number, but immortal in the English language, such as the "Song of the Shirt," the "Bridge of Sighs," and the "Song of the Labourer," which seized the deep human interests of the time, and transported them from the ground of social philosophy into the loftier domain of the imagination. They are no clamorous expressions of anger at the discrepancies and contrasts of humanity, but plain, solemn pictures of conditions of life, which neither the politician nor the moralist can deny to exist, and which they are imperatively called upon to remedy. Woman, in her wasted life, in her hurried death, here stands appealing to the society that degrades her, with a combination of eloquence and poetry, of forms of art at once instantaneous and permanent, and with a metrical energy and variety of which perhaps our language alone is capable. Prolonged illness brought on straitened circumstances; and application was made to Sir Robert Peel to place Mr Hood's name on the pension list, with which the British state so moderately rewards the national services of literary men. This was done without delay, and the pension was continued to his wife and family after his death, which occurred on the 3d of May 1845. Nine years after, a monument, raised by public subscription, in the cemetery of Kensal Green, was inaugurated with a concourse of spectators that showed how well the memory of the poet stood the test of time. Artizans came from a great distance to view and honour the image of the popular writer whose best efforts had been dedicated to the cause and the sufferings of the workers of the world; and literary men of all opinions gathered round the grave of one of their brethren whose writings were at once the delight of every boy, and the instruction of every man, who read them. Happy the humorist whose works and life are an illustration of the great moral truth that the sense of humour is the just balance of all the faculties of man, the best security against the pride of knowledge and the conceits of the imagination, the strongest inducement to submit with a wise and pious patience to the vicissitudes of human existence. This was the lesson that Thomas Hood left behind him, and which the people of this country will not easily forget. (R. M. M.)

HOOFFT, Peter Cornelius, an eminent Dutch poet and historian, and, with his great contemporary Vondel, the real founder of the Dutch stage, was born in 1581, at Amsterdam, of which city his father was burgomaster. After finishing his education at Leyden, he spent three years in foreign travelling, chiefly in France, Germany, and Italy. In the latter country in particular he devoted much time to the study of the mechanism of verse, which he mastered so thoroughly that his drama of *Granida*, published soon after his return home in 1601, is reckoned to this day one of the masterpieces of Danish literature, both for the harmony of its rhythm and the graceful elegance of its diction. In 1609 Hoofft was appointed *drossard* of Muiden, a village about 5 miles from Amsterdam, where he spent the remainder of his life. During the whole of this period his house was the rendezvous of all the cultivators of polite letters in Holland, who were attracted to it both by the literary renown and the great social and moral worth of the host. Hoofft was twice married, and on both occasions very happily. His first wife died in 1624; his second survived him.

Unlike most writers, Hoofft's fame is twofold. His merits as a historian and prose-writer are nowise inferior to his merits as a poet; and the services which he rendered to the prose literature of his country are both in kind and in degree as memorable as those which he rendered to the poetical. His *History of Holland*, one of the earliest, remains to this day one of the best of the Dutch classics, and is proudly pointed to by the countrymen of the author as a model of grace, purity, and vigour, both of thought and style. Hoofft displays most originality, however, in his *Minnedigte*, a collection of miscellaneous pieces in the style of Anacreon, whose grace, lightness, and fancy, have been very happily caught. In this vein he is still without a rival in Holland, unless perhaps Poot may claim the honour of that title. Hoofft died May 21, 1647, at the Hague, whither he had gone to attend the funeral rites of the Stadtholder Frederic Henry.

HOOGEVEEN, Heinrich, a Dutch scholar and philologer of considerable note, was born at Leyden in 1712. His parents, who were miserably poor, were hardly able to send him to the school of his native town, and when at length they procured the means their son made at first little or no progress in his studies, chiefly, it was believed, through the severity of his teacher. A change of masters, however, developed his latent abilities, and he soon distinguished himself so much that at the early age of twenty he was made co-rector of the school of Gorcum. In the following year he was called to organize the gymnasium of Woerden, which, despite his youth, he brought to a high state of prosperity. From Woerden he was transferred to Breda, and from Breda to Dordrecht, and at length found a permanent abode in Delft, where he died in 1791. His best work is a treatise on the *Greek Particles*, Leyden, 1769 (of which an excellent abridgment was published by Schütz, Leipzig, 1806), and his edition of Vigiers' work on *Greek Idioms*, which has been several times reprinted. Hoogeveen also wrote a large number of odes and elegies in Latin, in which kind of composition he had great facility and no mean talent. None of these works, however, display either high scholarship or very refined taste. Perhaps his most useful contribution to literature in his *Dictionarium Analogicum Linguæ Græcæ*, published at Cambridge in 1800. The value of this Lexicon is that all Greek words with the same termination follow each other in alphabetical order according to their final letters—a very convenient arrangement for conveniently tracing etymological analogies.

HOOGHLY, an extensive district in the province of Bengal, formerly called Saatgong, situated principally between the 22d and 23d degrees of north latitude, and extending a considerable distance along the right bank of the River Hooghly. It is bounded on the N. by the district of Burdwan, on the S. by the district of Hidjelee, on the E. by the River Hooghly, and on the W. by Midnapoor. This district consists of low flat land, very fertile; but that part which is nearest to the sea is very thinly inhabited; it is called the Sunderbund, is swampy, covered with wood, and remarkably unhealthy. It is intersected in every direction by rivers and their branches, which afford great facilities for internal navigation. Along the shores of the ocean salt of an excellent quality is manufactured on account of the government. The area, according to official return, is 2089 square miles. The population is given at 1,520,840, an amount which, compared with the area, indicates an extraordinary density of 728 to the square mile, and it is nevertheless considered that the numbers of the people are steadily on the increase. The French settlement of Chandernagore is situate within the limits of the district, as are also Chinsura and Serampore, now British possessions, but formerly belonging the first to the Dutch and the latter to the Danes. The right of the East India Company to the district originated in the treaty concluded with Meer Cossin in 1760.

Hooghly, an ancient, and formerly a large town in the province of Bengal, situated on the western bank of the Hooghly, nearly 26 miles above Calcutta, and supposed to have been founded by the Portuguese about the year 1538. During the Mogul government, it was a town of great consequence, being the port of the western arm of the Ganges, where the duties on merchandise were collected. It very soon drew away all the trade from Saatgong, which had been before the government port of Bengal. During the prevalence of the Portuguese dominion in India, Hooghly was fortified, and continued to flourish till the year 1632, when it was attacked by order of the Emperor Shah Jehan, and, after a siege of three months and a half, was taken by the Mogul troops, 1000 of the Portuguese being killed, and 4400 men, women, and children taken prisoners. From this period Hooghly became the imperial port. All the officers of the government were ordered to remove thither, and it was placed under the jurisdiction of a special governor. In the year 1676 the English, and soon afterwards the Dutch, obtained the permission of the native government to erect factories. After this period, every encouragment was given to commerce; and Hooghly, which was called Bukhshy Bunder, became a great commercial emporium between Europe, Persia, Arabia, and India. In 1686 hostilities commenced between the English and the Nawaub. An action ensued, in which the Nawaub's troops were defeated; and at the same time the town of Hooghly was cannonaded, and five hundred houses burned. In 1700 the East India Company's factory was transferred from Hooghly to Calcutta. The population of Hooghly is now estimated at 12,000. The town is situate on the line of railroad recently constructed from Calcutta to Burdwan. E. Long. 88. 22., N. Lat. 22. 54.

Hooghly *River*, properly the Bhagirutty, a river of Bengal, formed by the junction of the two westernmost branches of the Ganges, the Cossimbazar, and the Jellinghy. This is the port of Calcutta, being the only branch of the Ganges that is navigated by large vessels; yet the entrance to the river is rendered extremely dangerous and difficult, by reason of numerous sandbanks in it, which are frequently shifting. There is indeed a rumour afloat that the river is gradually silting up, and must eventually cease to be navigable. This would prove a fearful blow to the trade of Calcutta, and the proposed remedy is to connect the River Mutwal with the capital by railway or ship canal. During the prevalence of the S.W. monsoon, when a strong current sets in from the Bay of Bengal, the extraordinary phenomenon, termed by Europeans the "Bore," occasionally presents itself. It rises in waves 12 or 15 feet high, and rushes on at the rate of 20 miles an hour. It commences at Hooghly Point, where the river first contracts itself, and is perceptible above Hooghly town; and though the distance is above 70 miles, it traverses this space in about four hours, running along the opposite bank to the Calcutta side, whence it crosses at Chitpoor, about 4 miles above Fort William, and rushes with great violence past Barnagore, Duckingsore, &c., frequently oversetting boats and driving ships from their anchorage. At Calcutta it sometimes occasions an instantaneous rise of 5 feet. The tide does not rise more than 30 miles above Calcutta; and during the rainy season its influence is checked by the large body of water that comes down the river. The Hooghly contains several kinds of good fish, particularly *Ciprinus Anjana*, the mango fish, or *Polynemus paradoxus*, and prawns; and it abounds also in crocodiles and sharks. It is about three-quarters of a mile broad at Calcutta, and 8 or 10 miles wide at the mouth. It is only navigable for ships as high as the tide reaches, and the upper part of it is nearly dry during the hot season; yet there are few rivers that can boast of a more extensive commerce, its banks being studded with numerous towns and villages. It is esteemed by the Hindus to be the most sacred branch of the Ganges, and it is on this account that those who cannot afford to bury their dead throw them into the Hooghly.

HOOK, Theodore Edward, the son of James Hook, a musical composer of some merit, was born in London in 1788. At a too early age, and after a very flimsy education, he began life without a profession or definite views of any kind. While a mere boy he wrote a good many trashy farces and burlesques for the theatres; but the temporary success of a few of them tempted him to devote his life to authorship. He soon became better known, however, from his convivial talents, which floated him into the aristocratic society of London. There he frittered away in clever improvisations and other forms of social debauchery, talents that might have gained for him a respectable position in English literature. His inexhaustible wit, his daring practical jokes, his amazing power of punning, and his musical skill, made him a great favourite with the Prince Regent, who, in 1812, sent him to the Mauritius as treasurer of that island. The whole of Hook's past career had in an eminent degree disqualified him for such an office, and at the end of five years he was brought back to England a prisoner, under a charge of embezzling some L.12,000 of the public money. Subsequent investigation induced the government to drop the criminal charge; and Hook, though he never denied that a large sum (L.9000) of the public money had been lost, through his carelessness and unthrift, never exerted himself to repay it. After his liberation from jail, where he spent some months while his case was under trial, he established the *John Bull* newspaper. This journal had at first a large sale, and again opened to its editor a door into the world of fashion, where, as before, he shone with a fatal brilliancy. In the attempt to turn his social advantages to account, he wrote a number of novels of what has been called "the silver fork school," which was for a time the fashion. But gambling, hard living, and the strain of incessant writing, made the gay and sparkling wit one of the unhappiest men in England during the latter years of his life, and at the time of his death in 1841 he was utterly broken in mind, body, and estate. Some of his best novels, such as his *Sayings and Doings*, in three series, *Gilbert Gurney*, and *Jack Brag*, still find admirers among a certain class of readers, but their interest is entirely limited to the circles whose follies and fashions they describe.

HOOKAH, an oriental pipe used chiefly in Turkey, by which the smoke of the tobacco is made to pass through water in order to cool it and render it more grateful to the mouth.

HOOKE, Nathaniel, the author of a *History of Rome*, was born in Ireland, but in what year is unknown. His Roman History embraces the period extending from the foundation of the city to the time of Augustus. It was published in 4 vols. 4to, at intervals of nearly forty years between the appearance of the first and last volumes. He had died before the publication of vols. 3 and 4. His work possesses the virtues of acuteness and clearness. In opposition to Middleton, he defended the cause of the Plebeians against the Patricians. Hooke was a zealous Catholic. When Pope was dying, a priest was brought to hear his confession and grant him absolution. This priest was brought by Hooke. He had been employed and well paid by the Duchess of Marlborough for assisting her in writing her memoirs, but he was so zealous in attempting to convert the Duchess to Catholicism that a quarrel was the consequence. He was one of the sufferers from the South Sea Bubble. Besides his *Roman History*, he wrote *Observations upon the Roman Senate*, 4to, 1758, in which he advocated and extended the political views propounded in his *History*. He also translated from the French the *Vie de Fénélon*, and Ramsay's *Voyages de Cyrus*. He died in July 1763.

Hooke, *Robert*, one of the most ingenious philosophers, was born July 18, 1635, at Freshwater, in the Isle of Wight. His father was a clergyman, and he himself was originally destined for the church, but his studies were interrupted by weakly health. His leisure hours were spent in devising mechanical contrivances, and his construction of a wooden clock was a premonition of one sphere in which he was to excel. In 1648 his father died. After having been some time with Lely the painter, he went to Westminster School, and was initiated in mathematics and the learned languages, including Hebrew. In 1653 he went to Christ's Church College, Oxford. He appears to have turned his attention somewhat eagerly towards devising a method by which men should be able to elevate themselves in the air like birds, but without success. In 1655 he became assistant to Dr Willis in chemistry, and soon afterwards to the Honourable Robert Boyle. To the latter he was very serviceable in constructing the air-pump. In 1664 Sir John Cutler founded a mechanic school, of which in the beginning of next year Hooke was made Curator of Experiments for life. In 1666 he produced a model for rebuilding London after the great fire, but however much it was approved of, it was not carried into execution. Hooke, however, was employed as one of the surveyors—a post which was very lucrative. In 1677, by the death of Mr Oldenburgh, the office of secretary to the Royal Society became vacant, and Hooke was appointed to it. In 1687, after the death of his niece, who had lived with him, he was overwhelmed with grief. It affected his temper as well as his spirits, and his moodiness was still farther increased by a chancery suit between him and Sir John Cutler. In 1691 a warrant from Archbishop Tillotson conferred on him the degree of doctor of physic. In 1696 the chancery suit was determined in his favour. He died at his lodgings at Gresham College, March 3, 1702, and was buried in St Helen's Church, Bishopsgate Street, his remains being followed to the grave by all the members of the Royal Society. Hooke was remarkably inventive, but being also ambitious and jealous, he laid claim to inventions which had been made independently of him; and, distrustful, he accused others of making known his discoveries to rivals. His personal appearance was mean, he being short of stature, crooked, lean, and pale. His lank brown hair he allowed to grow long, and to hang over his face. He was penurious; and his melancholy and meagre appearance were rendered worse by the late hours which he kept at night. He wrote *Sectiones Culterianæ; Micrographia; A Description of Helioscopes; A Description of some Mechanical Improvements of Lamps and Waterpoises;* and from his papers Richard Waller published posthumous works. For a statement of his near approach to the discovery of gravitation, his improvements in clock-making, and his claim to other discoveries, see Playfair's Dissertation.

HOOKER, John, also called *Vowell*, the uncle of the famous author of the *Ecclesiastical Polity*, was born at Exeter in 1524. He received a college education at Oxford, and afterwards travelled on the Continent. He studied law at Cologne, and divinity at Strasbourg under Peter Martyr. Returning to his native country, he was made chamberlain of Exeter, the first who ever enjoyed that honour. In 1571 he became member of parliament for the same place. Three years previously to this, he had been sent to Ireland, where also he was elected a member of parliament. He died A.D. 1601. His work, *The Order and Usage of Keeping of the Parliaments in England*, was written for the use of the Irish Parliament. Also, in regard to Irish affairs, he made numerous additions to Holingshed's *Chronicles*, of which an edition appeared in

1586. He wrote a description of Exeter, a catalogue of its bishops, and an account of the duties, &c., of every sworn officer in it. He wrote also a work, *The Events of Comets, or Blazing Stars, made upon the sight of the Comet Pagonia*, a comet which appeared in 1577.

Hooker, *Richard*, the author of the *Ecclesiastical Polity*, was born in 1553 or 1554 at Heavy-tree, near Exeter, in the county of Devon. At the school of his native town he gave such assurance of "pregnant parts" that his teacher, taking an interest in his destiny, persuaded his uncle, John Hooker, a wealthy man, and the chamberlain of Exeter, to supply him with the means of completing his education at the university. A small allowance from this relative, a little similar aid from the famous John Jewel, Bishop of Salisbury, and a clerkship in Corpus Christi College, carried the young student comfortably through his academic career at Oxford. In 1573 he was admitted one of the twenty scholars of the Foundation, and four years later a fellow of the college. In 1579 he was appointed Hebrew lecturer to the university; but after discharging the duties of this office for three months, he, along with four other fellows of his college, was expelled by the vice-president. The grounds for this tyrannical act are unknown; but they must have been quite untenable, for in less than a month the ejected members were all restored. After an interval of three years Hooker took orders, and was appointed to preach at St Paul's Cross, London. On reaching the metropolis he repaired to the house of a Mr Churchman. This man's wife succeeded in persuading the young divine that "he was a man of a tender constitution; and that it was best for him to have a wife that might prove a nurse to him—such a one as might both prolong his life, and make it more comfortable; and such a one she could and would provide for him if he thought fit to marry." The guileless and unsuspecting minister agreed to abide by her choice, which fell upon her own daughter, Joan; and in the following year Hooker married her, "though," as Walton says, "she brought him neither beauty nor portion, and though her conditions were too like that wife's which is by Solomon compared to a dripping-house." She turned out a "silly, clownish woman, and withal a mere Xantippe." In 1584, on resigning his fellowship after his marriage, he was appointed to the living of Drayton-Beauchamp, in Buckinghamshire. During his incumbency of that parish two of his old pupils, Edwin Sandys and George Cranmer, took a journey to see their tutor. They found him, as old Izaak says, "with a book in his hand—it was the Odes of Horace—he being then, like humble and innocent Abel, tending his small allotment of sheep in a common field, which he told his pupils he was forced to do then, for that his servant was gone home to dine and assist his wife to do some necessary household business. But when his servant returned and released him, then his two pupils attended him unto his house, where their best entertainment was his quiet company, which was presently denied them; for *Richard was called to rock the cradle;* and the rest of their welcome was so like this, that they staid but till next morning, which was time enough to discover and pity their tutor's condition; and they having in that time rejoiced in the remembrance, and then paraphrased on many of the innocent recreations of their younger days, and other like diversions, and thereby given him as much present comfort as they were able, they were forced to leave him to the company of his wife Joan, and seek themselves a quieter lodging for next night. But at their parting from him, Mr Cranmer said, "Good tutor, I am sorry your lot is fallen in no better ground as to your parsonage; and more sorry that your wife proves not a more comfortable companion, after you have wearied yourself in your restless studies." To whom the good man replied, "My dear George, if saints have usually a double share in the miseries of this life, I that am none, ought not to repine at what my wise Creator hath appointed for me; but labour—as indeed I do daily—to submit mine to his will, and possess my soul in patience and peace." The Edwin Sandys here mentioned was a son of the Archbishop of York, and through the influence of this prelate Hooker was, in 1585, promoted to the mastership of the Temple in London, being then in his thirty-fourth year. On entering upon the duties of his new office he found that the afternoon lectureship was held by Walter Travers, a man of learning, ability, and personal worth, who had been ordained by the Presbytery of Antwerp, and was a vehement upholder of many of the doctrines of Calvin. These he advocated in his evening sermons; and in his zeal for their promotion carried on a warm correspondence with the leading reformers in Scotland and Geneva. Hooker, whose attachment to the English Church was no less ardent and sincere, soon found himself, much against his will, involved in a controversy with his colleague, giving occasion to a wit to observe that "the forenoon sermons spoke Canterbury, and the afternoon Geneva." The controversy at length threatened such evil consequences, that an interdict was laid on Traver's preaching by Archbishop Whitgift. Travers appealed, and petitioned the Privy Council, but without success. He then published his petition, and found many powerful adherents both in the Temple and elsewhere. Hooker made an able reply, which made him many friends among the upholders of the establishment; but "that he might unbeguile and win those of Mr Traver's judgment, he designed to write a sober deliberate treatise of the Church's power to make canons for the use of ceremonies, and by law to impose an obedience to them, as upon her children; and this he proposed to do in *Eight Books of the Laws of Ecclesiastical Polity*. To carry out this great plan in the peace and quiet which he could not find in the city, he begged to be translated to some country parsonage, and in 1591 was appointed to the living of Boscum, or Boscombe, in the diocese of Sarum in Wiltshire. In this rural retreat he completed the first four books of his *Ecclesiastical Polity*, which he published in 1594. In the following year he was transferred from Boscombe to Bishop's Bourne, near Canterbury, in Kent, where he remained till his death, Nov. 2, 1600. A few days before his death his house was broken into and robbed. When informed of the fact he only asked, "Are my books and written papers safe?" Being told that they were, he merely replied, "Then it matters not; for no other loss can trouble me." He lived to see the fifth book of his *Polity* through the press, but the remaining three were not published till 1647—nearly half a century after the author's death. In his personal character Hooker was one of the most amiable men whose names adorn the annals of the national church. Even in his youth he was remarked for the grave calmness and dignified modesty of his demeanour. The genuine mildness of his temper was proved in his controversy with the Nonconformists. His resigned and humble piety was memorable in an age that had many bright examples of that virtue to boast of.

Hooker's *Ecclesiastical Polity* marks an era in the history of English literature, to which he rendered services that have been amply acknowledged by critics of all shades of religious belief. Its literary merits are attested by Hallam, who says, that "Hooker not only opened the mine but explored the depths of our native eloquence. So stately and graceful is the march of his periods, so various the fall of his musical cadences upon the ear, so rich in images, so condensed in sentences, so grave and noble his diction, so little is there of vulgarity in his racy idiom, of pedantry in his learned phrase, that I know not whether any later writer has more admirably displayed the capacities of our language, or produced more passages worthy of comparison with the splendid monuments of antiquity. If we compare the first book of the *Ecclesiastical Polity* with what perhaps bears most resemblance to it of anything extant, the treatise of Cicero, *De Legibus*, it will appear somewhat perhaps inferior, through the imperfection of our language, which with all its force and dignity does not equal the Latin in either of these qualities, and certainly more tedious and diffuse in some of its reasonings, but by no means less high-toned in sentiment or less bright in fancy, and far more comprehensive and profound in the foundations of its philosophy." The substance of Hooker's argument is given under the head Episcopacy.

HOOLE, John, the translator of the *Gierusalemme Liberata* of Tasso, was born at Moorfields in 1727. His father intended him to follow the trade of watchmaking, but his being short-sighted was an insuperable objection. At the age of seventeen he became a clerk in the accountant's department in the East India House. He occupied his leisure time in learning Italian in order to read in the original the *Orlando Furioso* of Ariosto, Harrington's translation of which had greatly pleased him. His next step was to begin the work of translating. He commenced the *Jerusalem Delivered* in 1758. It was published with a dedication to the queen by Dr Johnson, in 1773. It is characterized by elegance and correctness, but exhibits little of the true genius of poetry. The *Orlando Furioso* was published in 5 vols. 8vo, 1773-1783. In the meantime he had become an auditor of accounts in the East India Company, an employment which took up much of his time. In 1792 he published *Rinaldo*, an early work of Tasso's. His translation of Metastasio's dramas and other poems display more spirit and variety. He composed some dramas for the stage, viz., *Cyrus*, 1768; *Timanthes*, 1770; and *Cleonice*, 1775. These were not successful. Hoole died at Dorking in 1813.

HOOPER, John, an English martyr, was born in Somersetshire, towards the close of the fifteenth century. He was educated at Oxford, where he took his degree of bachelor of arts in 1518. After becoming a Cistercian monk, he returned to Oxford, where the works of the continental reformer, in conjunction with the Holy Scriptures, opened his eyes to the errors of Popery. In 1539 he became chaplain to Sir John Arundel, but his leaning towards the principles of the reformers being discovered, he fled to France. Returning to England, he was again discovered, and escaped to Ireland, disguised as a sailor. From Ireland he again went to the Continent, and remained in Switzerland till Edward VI. ascended the throne in 1547. In 1550 he was consecrated Bishop of Gloucester, but his repugnance to using the robes of the bishops, which he considered relics of Popery, kept him back for some time from entering upon his episcopal duties. He was even committed to prison for non-compliance. In 1552 he was created Bishop of Worcester *in commendam*. In 1553, upon the accession of Queen Mary, he was seized and put in the Fleet. Upon examination he refused to recant his opinions, and was condemned to the flames. The sentence was executed in the beginning of 1555, when Hooper was in the 60th year of his age. He was zealous in the discharge of his sacred duties, and was a popular preacher. He wrote extensively on the controverted subjects of the day, and suffered martyrdom with great Christian fortitude.

HOOPING-COUGH, Chin-Cough or Kink-Cough (*Pertussis*), the *Coqueluche* of the French, is a disease to which children are liable, characterized by the presence of a strangulating convulsive cough, interspersed with a peculiar crowing sound or whoop, which cough returns at uncertain intervals in fits or paroxysms that usually pass off by vomiting. The disease appears to be contagious, and usually occurs but once during life; but if the child should within a year or so be affected with a bronchitic attack, the attending cough is very liable to assume a form resembling the convulsive paroxysms of this disease.

Hooping-cough begins exactly like a common cold, being usually attended with slight febrile symptoms and a cough. The true character of the malady may, however, be suspected if it is observed that the fits of coughing are most frequent and of longest duration during the night. It is not, however, till the cough has continued from a fortnight to three weeks that it assumes the true convulsive character, comes on in irresistible fits, and is attended with that peculiar prolonged crowing inspiration which characterizes the disease. The fits usually end in vomiting, or in the expectoration of a small quantity of mucous secretion.

Hooping-cough is a dangerous and fatal malady, and the more so the younger the child is. In its simple form it rarely proves fatal, but it is liable to three dangerous complications, to one or other of which the fatal result is usually attributable. These complications are,—1st, with bronchitis or pneumonia; 2d, with hydrocephalus and convulsions; and 3d, with infantile remittent fever. Pathology has as yet thrown no light on the nature of the disease.

In the simple form of the malady little treatment is necessary. Keeping the child in a warm equable temperature, attending to the state of the bowels, and giving, if requisite, some simple expectorant mixture, more with the view of favouring the termination of the fit by vomiting than with the view of checking the disease, is in general all that is necessary. When the hoop is fairly formed, change of scene and air in general causes the malady rapidly to subside. In many cases where the fits are severe, and the child delicate, much benefit is derived from the addition of quinine to the expectorant mixture. The effects of external application are, to say the least, doubtful. When the cases are complicated, they require the greatest attention to bring them to a successful issue, and all the usual means must be sedulously employed which are used in the treatment of each different complication. (J. S—K.)

HOORN, a fortified seaport town of Holland, province of North Holland, on the Zuider Zee, 20 miles N. by E. of Amsterdam. It carries on a considerable trade, though in this respect it is much inferior to what it once was. The exports are chiefly butter, cheese, cattle, herrings, and other kinds of provisions. The manufactures comprise woollen cloths, carpets, &c. Shipbuilding and the herring fishery are extensively carried on. It has a naval college. Hoorn was the birth-place of Schouten, who in 1616 discovered Cape Horn, and named it after his native town; and of Tasman, the discoverer of Van Diemen's Land and New Zealand. Pop. about 9000.

HOP (*Humulus lupulus*), a plant chiefly used in brewing. See Brewing and Agriculture.

HOPE, Thomas, the well-known author of *Anastasius, or Memoirs of a Modern Greek*, was descended of an ancient Scottish family, and was one of three brothers who had attained to great wealth and eminence as merchants in Amsterdam. In early manhood he travelled extensively in Europe, Asia, and Africa, and on settling down in London, became known as a munificent patron of art in all its branches. His first published work was a volume on *Household Furniture and Decorations*, which gave occasion to Sidney Smith to call its author "the gentleman of Sphinxes—the Œdipus of coal-boxes—he who meditated on muffineers, and planned pokers"—but which, despite the ridicule of the *Edinburgh* and other reviews, effected a great reform in the style of domestic arrangements in English houses. This book appeared in 1805, and four years later it was followed up by a sumptuous work on the *Costume of the Ancients*, and in 1812, by the no less splendid *Designs of Modern Costumes*. His great work, however, was his *Anastasius*. The hero of this work is a sort of Oriental Gil Blas, who is tossed about through all the conditions of life, and from being a beggar in the streets of Constantinople, rises to be an officer of distinction under a

Bey of Egypt. The strange scenes through which he passes in this motley career are described with a force and eloquence which, as Sidney Smith said, would not disgrace the pen of Tacitus, and with a depth of feeling and a vigour of imagination worthy of Lord Byron, to whom, indeed, the novel, on its first appearance, was very generally attributed. Turning from fiction to metaphysics, Hope next wrote an elaborate work on the *Origin and Prospects of Man*, which, however was not published until after his death. Amid much that is paradoxical, obscure, and fanciful, this work contains many ingenious views, some deep thinking, and occasional passages of striking eloquence. A parallel, in many respects true and correct, has been drawn between the author of *Vathek* and the author of *Anastasius*. Hope died February 3, 1831.

Hope, *Thomas Charles*, M.D., the eminent professor of chemistry for more than half a century in the universities of Glasgow and Edinburgh, was the third son of Dr John Hope, the first regius professor of botany in Edinburgh. Thomas Charles Hope was born on 21st July 1766, and died on 13th June 1844.

As might be expected, he early imbibed a predilection for botany, and had made such proficiency in that study that he aspired to obtain that chair on the death of his father in 1786. Having at the same time studied chemistry under the celebrated Dr Black, he applied himself with great industry to that science, which became his favourite pursuit; and when the chemical chair in the University of Glasgow became vacant, on the death of Dr Irvine in 1787, Hope was chosen as his successor. Aware of what might be required from the successor to the several eminent men who had preceded him in that appointment, viz., Cullen, Black, Robison, and Irvine, the young professor was stimulated to increased exertion, and soon became a favourite teacher of chemical science.

When Hope commenced his chemical prelections, the doctrines of the Stahlian school were universally received and taught. But in 1787 Sir James Hall returned from Paris to Scotland, and soon convinced Hope of the vast superiority of the Lavoisierian theory of combustion and oxygenation to the hypothesis of phlogiston. He became a convert to the new doctrines; and next winter zealously taught them in his class.

In 1783 Dr Hope became a member of the Royal Society of Edinburgh, and in the summer of that year paid a visit to Paris, where he was received with marked attention by Lavoisier and Berthollet,—an honour which he ascribed to his having been a pupil of Black, but which probably was no less owing to his having been introduced as the first British chemist who had publicly taught the new French chemical philosophy.

With the view of becoming a practical physician, Dr Hope had for two years, along with his chemical class, assisted his uncle, Professor Stevenson, in teaching the practice of medicine in the University of Glasgow; and, on the death of that uncle, succeeded him in that office, when he resigned the chair of chemistry. Yet he continued his chemical studies in private; and it was during this period that he made his principal discovery, the presence of a new earth in a mineral which had been confounded with barytes. The mineral was found in strontian lead-mines, in Argyllshire, from which circumstance Hope named this earth *strontites*. In this masterly analysis he pointed out the chemical characters that distinguish the two earths, and laid the results before the Royal Society of his native city in 1793, which established his reputation as an expert analytic chemist. This discovery has been attributed to several other persons, but the only one whose pretensions are deserving of notice is Klaproth, who, in the journal *Chemische Annalen* for 1793-94, pointed out the distinction between the minerals *strontianite* and *witherite*. Yet though Hope's experiments precede those of Klaproth, both may be considered as original investigators of this earthy body.

The success and popularity of Hope's teaching at Glasgow suggested in 1795 to Dr Black, then in declining health, the advantage of obtaining his assistance; and, with the consent of the patrons of the university, Black made him the offer of becoming his assistant and successor in the chemical chair. It was accepted by Dr Hope, who resigned his prospects in Glasgow, and came to reside in Edinburgh. For two years he assisted Dr Black in the duties of the chair, but from 1798 the whole task devolved on Dr Hope. He soon became sole professor, and continued to fulfil the important duties of the chair till the end of the session of 1843.

Those who have had the advantage of being Hope's pupils have acknowledged the interest and instruction they derived from his able prelections, and very happily-executed experimental illustrations of the leading principles of chemistry. These qualities made him the most popular teacher of the science of his day in Britain; and his class-room for many years was constantly crowded to excess. The students in his course of 1799 were about 400, in 1813 they amounted to 500, and in 1827 to 575. During his career in Edinburgh his pupils amounted to 16,800.

Some persons have been surprised that Dr Hope, who had so auspiciously commenced his experimental career, should have apparently abandoned the pursuit of original research. But he considered his chief duty as a teacher to demand his utmost efforts to improve his lectures, and to devise the most characteristic and striking experimental illustrations, and in this he succeeded almost beyond any of his contemporaries. He did not, however, wholly give up original research; and some of his communications to the Royal Society are on important scientific questions. In 1804 he produced some ingenious experiments "On the Point of greatest Density of Water," which he fixed at temperature 39° 5' Fahr. (see *Edin. Phil. Trans.* for 1805). In the same paper he demonstrated the fallacy of Rumford's idea that fluids are absolute non-conductors of heat, which were afterwards confirmed by Thomson, Dalton, and Traill. Another curious paper appears in the *Transactions* in 1836—"Observations and Experiments on the Coloured and Colourable matters in Leaves and Flowers of Plants, upon which Acids and Alkalis act in producing red, yellow, or green colours." In the same year he read a paper "On the Chemical nomenclature of Inorganic Compounds." To Dr Hope, also, we owe a decided improvement on the Eudiometer of Scheele. The year before his death he communicated two papers to the Royal Society—1. "Observations on the flowers of *Camellia japonica*, *Magnolia grandiflora*, and *Chrysanthemum leucanthemum*," in each of which he discovered the existence of a distinct proximate principle to which he gave the names of *camelline*, *magnoline*, and *chrysanthemine*. 2. "An attempt to explain the Phenomena of the Freezing Cavern at Orenburg." Such are his chief contributions to science; but he considered *teaching* as the great business of his life, and to this he made it his duty to devote his chief energies. See Dr Traill's *Memoir of Hope* (*Edin. Phil. Trans.* xvi.).

HOPITAL, Guillaume François Antoine, Marquis de l', a celebrated French mathematician, was born at Paris in 1661. Entering the army, he served for some time in a cavalry regiment, but his bad eyesight, and a strong desire to pursue the study of mathematics, induced him to retire into private life. At a very early age he had given proof of a strong bent as well as of a large capacity for the pure sciences. One day at the table of the Duc de Rohan, a problem was mentioned, for which it was said that Pascal after long thinking had found an elegant solution. De l'Hôpital, then a lad of fifteen, astonished the savants who were admiring the neatness of Pascal's method by declaring that he believed he could solve it otherwise, and in a few days he did send in a correct solution on a totally different principle. Towards the close of the seventeenth century the *calculus* was beginning slowly, and amid fierce opposition, to force its way into general acceptance among the mathematicians of Europe. One of its ablest advocates, John Bernouilli, coming to Paris, was engaged by De l'Hôpital to give him instructions in it, and spent some time in the marquis's house, teaching him the higher mathematics. So great was De l'Hôpital's progress, that when his tutor propounded to the mathematicians of Europe his famous problem of the curve of quickest descent he was the only Frenchman who sent in a solution. De l'Hôpital now became one of the warmest supporters of the *calculus*, and indeed wrote the first systematic treatise on it, which appeared at Paris in 1696, under the title of *L'Analyse des Infiniment Petits*. In the preparation of this work De l'Hôpital is said, though apparently on insufficient grounds, to have been unduly aided by his old tutor Bernouilli. This work, which may be fairly regarded as marking an era in the history of mathematical science, was frequently reprinted in the course of the eighteenth century. Not long after De l'Hôpital's death, which took place in 1704, a treatise on the conic sections, which he had left in MS., was published, and long maintained its ground as the standard work on this department of mathematics. See Playfair's Dissertation, prefixed to this work.

Hôpital or **Hospital**, *Michel de l'*, chancellor of France, was born at Aigueperse in Auvergne, in the year 1505. His father, Jean de l'Hôpital, who was at once physician and councillor to the Constable of Bourbon, sent him to study law, first at Toulouse, and afterwards at Padua, the legal school of which then enjoyed great celebrity. In that age jurisprudence was the principal science cultivated, and no one could aspire to any employment without having studied it profoundly. L'Hôpital, although he had already acquired the elements of this science in France, spent six years at Padua in improving himself in it; he also applied himself to the study of the belles lettres, in which he made rapid progress, and at the same time cultivated the Greek and the Latin languages, with which he rendered himself perfectly familiar. Having completed his studies, and finding his prospects clouded by the death of the Cardinal de Grammont, who had induced him to return to France, and upon whose influence he had placed his hopes of preferment, he entered himself of the bar at Paris. In this profession, his merit and virtue were soon appreciated. At the end of three years, Jean Morin, criminal-lieutenant, a person famous in the martyrology of the Protestants, on account of the severity with which he enforced the laws enacted against them, gave L'Hôpital his daughter in marriage, and at the same time conferred upon him the office of counsellor to the parliament of Paris as her dowry.

In this situation, which he held during twelve years, the toleration he displayed formed a remarkable contrast to the unrelenting severity by which his father-in-law had rendered himself but too celebrated. When L'Hôpital entered the parliament, that once illustrious body had much degenerated, owing to the venality introduced or at least overlooked by Francis I. A witness of this corruption, L'Hôpital deplored its consequences, and, in concert with some old magistrates who still remained, endeavoured to set an example of assiduity and application to a crowd of inexperienced young men, who, by venality, had obtained admission into the parliament, and who had no other title to that honour but the money they had paid for it. L'Hôpital was long cited as a model in the magistracy. He made it a rule to listen with patience, to interrupt no one, to express himself as concisely as possible, and to oppose all unnecessary delays; he was also punctual in his attendance in court, where he generally remained until the business of the day had been regularly gone through, and always rose with reluctance, however late, if any portion of it remained unattended to. In short, he was a laborious and conscientious judge, who to great talents united the most steady and persevering industry. The vacations made no material change in his way of life; his pursuits were indeed different, but his application was the same; the perusal of the great writers of antiquity, the study of French history, and the reading of the Holy Scriptures, each in its turn formed the occupation of his leisure time. "There is nothing frivolous in my amusements," says he, in one of his letters; "sometimes Xenophon is the companion of my walks; sometimes the divine Plato regales me with the discourses of Socrates. History and poetry have their turns; but my chief delight is in the sacred writings."

The next appointment which L'Hôpital received was that conferred upon him by Henri II. of envoy or ambassador to the Council of Trent, which was then sitting at Bologna. But having soon grown tired of the inactivity to which he found himself reduced, he was, at his own desire, recalled, and, upon his return, experienced some coldness on the part of the court, which did not altogether relish his evident disinclination to assist in the proceedings of that famous council. The coldness, however, proved only temporary, for ere long he was appointed master of the requests. In 1554 he was made director and superintendent of the royal finances in the chamber of accounts. At this time the finances required a guardian at once vigilant and faithful. Enormous abuses prevailed in the whole fiscal administration. On the one hand there existed profusion without limits, and on the other malversation without shame. Scarcely a third, or even a fourth part of the sums collected, ever reached the royal treasury; the people were exposed to the most grinding exactions, yet the revenue was in a state of gradual decline. To put an end to these disorders, L'Hôpital revived the ancient laws which had fallen into desuetude; he struck terror into defaulters by some examples of wholesome severity; he refused to sanction any expenditure except for the immediate purposes of the state; he defied the enmity of that numerous and vindictive class whose dishonest gains he had destroyed; and he acted with so much personal disinterestedness, that, after having been five years in office, he was unable to give a portion to his daughter, and the deficiency was supplied by the liberality of the sovereign.

After the fatal accident which, in 1559, put an end to the life of the king, the Cardinal de Lorraine, then at the head of affairs, introduced L'Hôpital into the council of state; but as one of the articles of the treaty of Chateau-Cambrésis had provided that the Duchess De Berri, his benefactress, should espouse Emanuel-Philibert, Duke of Savoy, he was appointed to conduct that princess into Piedmont, whither he attended her in the capacity of chancellor. The distracted situation of France, however, soon made it necessary to recall a man of such undaunted firmness and inflexible integrity. In the midst of faction, turbulence, and confusion, when the passions of men appeared, like the evil spirits, to have been for a season unchained, he was advanced to the office of chancellor of France, and in this elevated station conducted himself like a philosopher and a hero. At this period the destruction of the Protestants had been determined on; it was resolved to leave them no alternative but abjuration or death; and it was even meditated to establish the inquisition in France. The new chancellor durst not attack this project directly, without compromising himself with the governing party; but he sought indirectly to defeat the odious design, and by the edict of Remorantin, which declared the crime of heresy to be cognisable only by the ecclesiastical judge, he ultimately accomplished his beneficent design, and thus decided the clergy to abandon all idea of establishing the inquisition, which, they knew, would be powerless when deprived of the aid of the secular arm. Upon all occasions, indeed, he was the advocate of mercy and reconciliation, and a declared enemy to persecution on account of religion; and hence the more bigoted Romanists, offended at his wisdom and moderation, accused him of being a concealed Protestant, unconscious that by such suspicions and accusations they paid the highest compliments to the spirit of that faith which they were so desirous to eradicate. With a man of such character, ability, and firmness, at the head of affairs, it was hopeless to attempt to carry through the violent measures which were already contemplated; yet when the question of giving him a successor came to be seriously agitated, Catherine de Medici found herself involved in very great perplexity. The ancient relations of L'Hôpital with the House of Lorraine; the estimation in which he was universally held; his known love of his country, which, in his mind, absorbed all other affections; and the difficulty of finding any one to fill his place, who would not sink into insignificance and contempt in comparison with this truly great man—were serious obstacles to his removal; but as nothing could induce him to abandon or change the pacific character of his measures, all other considerations were at length disregarded, and the queen excluded him from the council of war, upon which he immediately withdrew to his country-house at Vignay, near Estampes.

His exclusion from the council was accompanied with insult. The Constable of Montmorency told him that a man of his profession, a civilian, ought not to intermeddle in what related to war. "That is a subject," said the constable, "on which you are not qualified to give advice." "True," replied the chancellor, "I do not know how to make war, but *I know when it is necessary*." Several days after his retirement from office, when the seals were demanded of him, he resigned them without regret, observing that the affairs of the world were too corrupt for him to meddle with them. He spent his time in lettered ease, amusing himself with writing Latin poetry, and enjoying the society of some select friends, until his peace was broken by the bloody tragedy of St Bartholomew, which, with his usual sagacity, he had foreseen. Of this barbarous and inexpiable massacre the judgment he pronounced has been ratified by posterity. He himself narrowly escaped being one of its victims. The inhabitants of the country had risen, and were devastating the fields, and dragging the farmers in chains towards the city. But the queen, anxious about his fate, sent a detachment of cavalry for his protection. The sudden apparition of this troop, whose destination was unknown, produced great consternation in his house, which was open on all sides. He was asked by the inmates if they would close the gates. "No, no," said he; "if the small gate will not admit them, throw open the large one." When informed that the persons who prepared the lists of proscription had pardoned him the opposition which he had always given to their projects; "I did not know," replied he coldly, "that I had done any thing to deserve either pardon or death." But what most deeply affected L'Hôpital on this mournful occasion, was the danger to which his daughter, who happened to be in Paris, was in consequence exposed. She was saved by the interference of Anne d'Este, duchess of Guise, whom L'Hôpital thanked for this signal service, in an epistle overflowing with the warmest feelings of paternal gratitude. These cruel events, however, deeply affected his health and spirits, and he died at Vignay, on the 13th of March 1573, at the age of sixty-eight, and less than one year after the massacre.

"L'Hôpital," says Brantôme, "was the greatest, worthiest, and most learned chancellor that was ever known in France. His large white beard, pale countenance, and austere manner, made all who saw him think they beheld a true portrait of St Jerome, and, in fact, he was called St Jerome by the courtiers. All orders of men feared him, particularly the members of the courts of justice; and when he examined them on their lives, their discharge of their duties, their capacities, or their knowledge, and particularly when he examined candidates for offices, and found them deficient, he made them feel it. He was profoundly versed in polite learning, very eloquent, and an excellent poet. His severity was never ill-natured; he made due allowance for the imperfections of human nature; he was always equal and firm. After his death his very enemies acknowledged that he was the greatest magistrate whom France had known, and that they did not expect to see such another." The productions of L'Hôpital are—1. *Latin poems*; 2. *Speeches delivered at the meeting of the States at Orleans*; 3. *Mémoires, contenant plusieurs Traités de Paix*, &c., from 1551 to 1560, Cologne, 1672, in 12mo. A work which he had undertaken on law is lost; and it is said that he had also projected a history of his own time, on the model of the ancient historians; but of this no part appears to have been executed. In 1807, M. Bernardi published his *Essai sur la Vie, les Ecrits, et les Loix de Michel de l'Hôpital*, in one volume 8vo, from which and other documents Mr Charles Butler published his Essay on the Life of L'Hôpital, principally with the view of exhibiting him as a friend of toleration. An admirable life and estimate of De l'Hôpital will also be found in Villemain's *Nouveaux Mélanges Littéraires*. (J. B—E.)

HOPKINS, EZEKIEL, bishop of Londonderry, and one of the standard theologians of England, was born in 1663 at Stanford, in Devonshire, of which his father was curate. His early education was conducted under Presbyterian and Independent influences,—a fact which threatened at first to mar his prospects of church preferment. On leaving Oxford, where he had been one of the choristers, and finally chaplain of Magdalen College, he was presented to the living of St Mary Woolnoth, in London. When the great plague broke out in the capital, Hopkins withdrew to Exeter, where he obtained the living of St Mary's. Here he married Araminta, a daughter of Lord Robartes; and when that nobleman was made lord-lieutenant of Ireland, Hopkins went with him to Dublin, and through his influence obtained the deanery of Raphoe. In 1671 he was made bishop of that diocese, and ten years later was translated to the see of Londonderry. In the famous siege of that town by the Irish adherents of James II. in 1689, Hopkins showed how completely he had rid himself of the influences of his early training by preaching with the most earnest zeal the doctrines of non-resistance. In the words of Macaulay, "he exhorted his flock to go patiently to the slaughter rather than incur the guilt of disobeying the Lord's anointed." In the course of the siege he withdrew from the town, and retired first to Raphoe and afterwards to London, where he was made rector of St Mary Aldermanbury. This charge he held till his death in June 1690. Hopkins' works, which have been frequently republished, comprise *Sermons*, *Expositions of the Decalogue and the Lord's Prayer*, and elaborate discourses on *Regeneration* and *The Vanity of the World*. The purely literary merits of these treatises are very great. In that sententious brevity which compresses whole chapters and volumes of meaning into a single line, Charnock was in that day without a rival, yet many of Hopkins' thoughts are expressed with a proverbial force and conciseness not unworthy of his great contemporary. His works are a mine of jewels. Their solid worth, apart from all ornament, their sound theology, their deep spiritual fervour, their practical good sense, and the acquaintance which they display with the nature and heart of man, commend them to our high esteem. But beside all this, the purity of their style, the clearness and vigour of their thought, and the abounding beauty of their illustrations, place them in some respects far above the average of the pulpit productions of the best known contemporary authors. Regarded by the Puritans, or at least by some of them, as a deserter from their ranks, buried in the obscurity of an Irish bishopric, Hopkins has never had due justice paid to his memory and worth. A candid perusal of his works will suffice to prove his title to rank with the best and ablest divines that England had to boast of in the seventeenth century.

HOR, a mountain of Arabia Petræa, on the confines of Idumæa, and forming part of the mountain of Seir or Edom. It is generally regarded as the modern *Jebel Haroun*, or Mount Aaron, lying midway between the Dead Sea and the Elanitic Gulf. On the summit of this hill is a tomb, venerated by the Mohammedans as the sepulchre of the high priest Aaron.

HORAPOLLO, or HORUS APOLLO. See HIEROGLYPHICS.

HORATII, three brothers of the Horatian gens, who figure in one of the old Roman legends. See ROMAN HIST.

HORATIUS FLACCUS, QUINTUS, the most popular, and, next to Catullus and Virgil, the greatest of the Roman poets, was born vi. Id. Dec. A.U.C. 689 (Dec. 8, B.C. 65), during the consulship of L. Aurelius Cotta and L. Manlius Torquatus, and died Nov. 27, A.U.C. 746 (B.C. 8). Horace is his own biographer. All the material facts of his personal history are to be gathered from the allusions scattered throughout his poems. A memoir, attributed to Suetonius, of somewhat doubtful authenticity, furnishes a few additional details, but none of material moment, either as to his character or career. His father was a freedman (*Sat.* I. vi., 6, 46-47), and it was long considered that he had been a slave of some member of the great family of the Horatii, whose name he had assumed, in accordance with the common usage in such cases. But this theory has latterly given place to the suggestion, based upon inscriptions, that he was a freedman of the town of Venusia (the modern Venosa), the inhabitants of which belonged to the Horatian tribe (G. F. Grotefend, *Encyclopädie von Ersch und Gruber*, 2d sec., vol. x., p. 457, Leipzig, 1833; and C. L. Grotefend, *Ephemerid. Literar.*, Darmstadt, 1834, p. 182; and Mommsen's *Inscriptiones Regni Neapolitani*, Lipsiæ, 1852). The point is, however, of little importance, as the name, distinguished as it was, has derived more lustre from the poet than from any of the patriots and heroes by whom it had previously been borne. The elder Horace had received his manumission before his son was born (*Sat.* I. vi., 8). He had realized a moderate independence in the vocation of *coactor*, a name borne indifferently by the collectors of public revenue, and of money at sales by public auction. To which of these classes he belonged is uncertain, but most probably to the latter (*Sat.* I. vi., 86). With the fruits of his industry he had purchased a small property near Venusia, upon the banks of the Aufidus, the modern Ofanto, in the midst of the Apennines, upon the doubtful boundaries of Lucania and Apulia. Here the poet was born, and in this picturesque region of mountain, forest, and stream, the boy became imbued with the love of nature, which distinguished him through life. The third ode of the fourth book affords a pleasing glimpse of the child, wandering out of bounds along the slopes of Mount Vultur, and being found, after an anxious search, asleep under a covering of laurel and myrtle leaves, which the wild pigeons had spread to shield this special favourite of the gods from the snakes and wild animals. The augury of the future poet, said to have been drawn from the incident at the time, was no doubt an afterthought of the poet's own, but the picture which the lines present of the strayed child asleep with his hands full of spring flowers is welcome, whatever may be thought of the omen. In his father's house, and in those of the Apulian peasantry around him, Horace had opportunities of becoming familiar with the simple virtues of the poor—their independence, integrity, chastity, and homely worth, which he loved to contrast with the luxury and vice of imperial Rome. Of his mother no mention occurs, directly or indirectly, throughout his poems, and it is reasonable to infer from this circumstance, taken in connection with the indications which they present of strong natural affection, that she died during his infancy. He appears also to have been an only child. No doubt he had at an early age given evidence of superior powers, and to this it may have been in some measure owing that his father thought him worthy of a higher education than could be obtained under a provincial schoolmaster (*Sat.* I. vi., 71, *et seq.*), and, although but ill able to afford it, carried him to Rome when about twelve years old, and gave him the best education which the capital could supply. No expense was spared to save the boy from any sense of inferiority among his fellow-scholars of the higher ranks. He was waited on by numerous slaves, as though he were the heir to a considerable fortune. But at the same time he was not allowed to entertain any shame for his own order, or to aspire to a position which he was unequal to maintain. His father taught him to look forward to filling some situation akin to that in which he had himself acquired a competency, and to feel that in any sphere culture and self-respect must command influence, and afford the best guarantee for happiness. Under the stern tutorage of Orbilius Pupillus, a grammarian of high standing, richer in reputation than gold, whom the poet has condemned to a bad immortality for his flogging propensities, he learned grammar, and became familiar with the earlier Latin writers, and with Homer. He also acquired such other branches of instruction as were usually learned by the sons of Romans of the higher ranks. But, what was of still more importance, during this critical period of his first introduction to the seductions of the capital, he enjoyed the advantage of his father's personal superintendence, and of a moral training, which kept him aloof, not merely from the indulgence, but even from the contact of vice. His father went with him to all his classes (*Sat.* I. vi., 81, *et seq.*), and, being himself a man of shrewd observation and natural humour, he gave his son's studies a practical bearing, by directing his attention to the follies and vices of the luxurious and dissolute society around him (*Sat.* I. iv., 105, *et seq.*), and showing their incompatibility with the dictates of reason and common sense. From this admirable father, Horace appears to have inherited that manly independence for which he was remarkable, and which, while assigning to all ranks their due influence and respect, never either overestimates or compromises its own. Under the homely exterior of the Apulian freedman we see the soul of the gentleman. His influence on his son was manifestly great. In the full maturity of his powers Horace penned a tribute to his worth (*Sat.* I. vi., 68, *et seq.*) with a fervour manifestly prompted by the full heart of a man who had often had cause to feel the blessings of that influence throughout the vicissitudes of a chequered life. It had given tone and strength to his character, and in the midst of manifold temptations had kept him true to himself and his genius.

At what age Horace lost his father is uncertain. Most probably this event occurred before he left Rome for Athens to complete his education, as was then the practice, in the Greek literature and philosophy, under native teachers. This he did some time between the age of seventeen and twenty. At Athens he found many young men of the leading Roman families—Bibulus, Acidinus, Messala, and the younger Cicero—engaged in the same pursuits with himself. His works prove him to have been no careless student of the classics of Grecian literature, and with a natural enthusiasm he made his first poetical essays in their flexible and noble language. With his usual good sense, however, he soon abandoned the hopeless task of emulating the Greek writers on their own ground, and directed his efforts to transfusing into his own language some of the grace and melody of these masters of song (*Sat.* i. x., 31–35). In the political lull between the battle of Pharsalia, A.U.C. 706 (B.C. 48), and the death of Julius Cæsar, A.U.C. 710 (B.C. 44), Horace was enabled to devote himself without interruption to the tranquil pursuits of the scholar. But when after the latter event Brutus came to Athens, and the patrician youth of Rome, fired with zeal for the cause of republican liberty, joined his standard, Horace was infected by the general enthusiasm, and accepted a military command in the army which was destined to encounter the legions of Anthony and Octavius. His rank was that of tribune, equivalent to a colonelcy of foot in our own army, and for this he must have been indebted either to the personal friendship of Brutus, or to an extraordinary dearth of officers, seeing that he was not only without experience or birth to recommend him, but possessed no particular aptitude, physical or moral, for a military life. His appointment excited jealousy among his brother officers, who considered that the command of a Roman legion should have been reserved for men of nobler blood. (*Sat.* I. vi., 46, *et seq.*) It was probably here that he first came into direct collision with the aristocratic prejudices which the training of his father had taught him to defy, and which, at a subsequent period, grudged to the freedman's son the friendship of the emperor and of Mæcenas. At the same time he had doubtless a strong party of friends, who had learned to appreciate his genius and attractive qualities. It is certain that he secured the esteem of his commanders, and bore an active part in the perils and difficulties of the campaign, which terminated in the total defeat of the republican party at Philippi, A.U.C. 712 (B.C. 42). A playful allusion by himself to the events of that disastrous field (*Odes*, II. vi., 9, *et seq.*) has been turned by many of his commentators into an admission of his own cowardice. This is absurd. Such a confession is the very last which any man, least of all a Roman, would make. Horace says, addressing his friend Pompeius Varius—

> "With thee I shared Philippi's fiery flight,
> My shield behind me left, which was not well,
> When all that brave array was broke, and fell
> In the vile dust full many a towering wight."

Such an allusion to the loss of his shield could only have been dropped by a man who felt that he had done his duty, and that it was known he had done it. The lines may thus be safely regarded, according to the views of Lessing and others, as a not ungraceful compliment to his friend, who continued the struggle against the triumvirate with the party who threw themselves into the fleet of Sextus Pompeius. This interpretation is confirmed by the language of the next verse, where, in the same spirit, he applies the epithet "paventem" (craven) to himself.

> "But me, poor craven, swift Mercurius bore,
> Wrapp'd in a cloud through all the hostile din,
> While war's tumultuous eddies, closing in,
> Swept thee away into the strife once more."

It was no shame in Horace to have despaired of a cause which its leaders had given up. After the suicide of Brutus and Cassius the continuance of the contest was hopeless; and Horace may in his short military career have seen, in the jealousy and selfish ambition of many of his party, enough to make him suspicious of success, even if that had been attainable. Republicans who sneered at the freedman's son were not likely to found any system of liberty worthy of the name.

When Horace found his way back to Italy it was to find his paternal acres confiscated. His life was spared, but nothing was left him to sustain it but his pen and his good spirits. He had to write for bread—*Paupertas impulit audax ut versus facerem* (*Epis.* II. ii., 51)—and in so doing he appears to have acquired not only considerable repute, but also sufficient means to purchase the place of scribe in the Quæstor's office, a sort of sinecure Clerkship of the Treasury, which he continued to hold for many years, if not to the close of his life (*Sat.* II. vi., 36). It was upon his return to Rome that he made the acquaintance of Virgil and Varius, who were already famous, and to them he was indebted for his introduction to Mæcenas. The particulars of his first interview with his patron he has himself recorded (*Sat.* I. vi., 55, *et seq.*) It is a curious circumstance in the history of a friendship, among the closest and most affectionate on record, that nine months elapsed after their meeting before Mæcenas again summoned the poet to his house, and enrolled him in the list of his intimate friends. This event took place in the third year after the battle of Philippi; and as the only claim of Horace, the man of humble origin and the retainer of a defeated party, to the notice of the minister of Augustus must have been his literary reputation, it is obvious that even at this early period he had established his position among the wits and men of letters in the capital. The acquaintance rapidly ripened into mutual esteem. It secured the position of the poet in society, and the generosity of the statesman placed him above the anxieties of a literary life. Throughout the intimate intercourse of thirty years which ensued there was no trace of condescension on the one hand, nor of servility on the other. Mæcenas gave the poet the place next his heart. He must have respected the man who never used his influence to obtain those favours which were within the disposal of the emperor's minister, who cherished an honest pride in his own station, and who could be grateful without being obsequious. Horace is never weary of acknowledging how much he owes to his friend. When he praises him, it is without flattery. When he soothes his anxieties, or calms his fears, the sincerity of his sympathy is apparent in the warmth of his words. When he resists his patron's wishes, he is firm without rudeness. When he sports with his foibles, he is familiar without the slightest shade of impertinence.

By Mæcenas Horace was introduced to Octavius, most probably soon after the period just referred to. In A.U.C. 717, a year after Horace had been admitted into the circle of his friends, Mæcenas went to Brundusium, charged by Octavius to negotiate a treaty with Marcus Antonius. On this journey he was accompanied by Horace, who has left a graphic record of its incidents (*Sat.* I. v.) It is probable that on this occasion or about this time the poet was brought to the notice of the future emperor. Between the time of his return from this journey and the year 722, Horace, who had in the meantime given to the world many of his poems, including the ten *Satires* of the first book, received from Mæcenas the gift of the Sabine farm, which at once afforded him a competency and all the pleasures of a country life. The gift was a slight one for Mæcenas to bestow, but he no doubt made it as the fittest and most welcome which he could have offered to his friend. It made Horace happy. It gave him leisure and amusement, and opportunities for that calm intercourse with nature which he "needed for his spirit's health." Never was a gift better bestowed or better requited. It at once prompted much of that poetry which has made Mæcenas famous, and has afforded ever new delight to successive generations. The Sabine farm was situated in a romantic valley about 15 miles from Tibur (Tivoli), and among its other charms, possessed the valuable attraction for Horace, that it was within an easy distance of Rome. When his spirits wanted the stimulus of society or the bustle of the capital, which they often did, his ambling mule could speedily convey him thither; and when jaded on the other hand by

> "The noise, and strife, and questions wearisome,
> And the vain splendours of imperial Rome,"

he could by the same easy means of transport, in a few hours bury himself among the hills, and there, under the shadow of his favourite Lucretilis, or by the banks of the Digentia, either stretch himself to dream upon the grass, lulled by the murmurs of the stream, or look after the culture of his fields, and fancy himself a farmer. The site of this farm has been pretty accurately ascertained, and it is at the present day a favourite resort of travellers, especially of Englishmen, who visit it in such numbers, and trace its features with so much enthusiasm, that the resident peasantry, "who cannot conceive of any other source of interest in one so long dead and unsainted, than that of co-patriotism or consanguinity," believe Horace to have been an Englishman (*Letter* by Mr Dennis. Milman's *Horace*, London, 1849, p. 109). The property was of moderate size, and produced corn, olives, and wine, but was not highly cultivated. Here Horace spent a considerable part of every year. Latterly, when his health failed, he passed the winter in the milder air of a villa at Tivoli. The Sabine farm was very retired, being about four miles from Varia (Vico Varo), the nearest town, well covered with timber, and traversed by a small but sparkling stream. It gave employment to five families of free *coloni*, who were under the superintendence of a bailiff; and, besides these, eight slaves were attached to the poet's establishment. With his inexpensive habits this little property was sufficient for all his wants (*Satis beatus unicis Sabinis*). Here he could entertain a stray friend from town,—his patron Mæcenas, upon occasion,—and the delights of this agreeable retreat and the charm of the poet's society, were doubtless more than a compensation for the plain fare or the thin home-grown wine, *Vile Sabinum*, with which its resources alone enabled him to regale them.

The life of Horace from the time of his intimacy with Mæcenas appears to have been one of comparative ease and of great social enjoyment. Augustus soon admitted him to his favour, and sought to attach him to his person in the capacity of secretary. This offer Horace was prudent and firm enough to decline; while at the same time he had the tact not to offend the master of the world by his refusal. To the close of his life his favour at court continued without a cloud. Augustus not only liked the man, but entertained a profound admiration for the poet. Believing in the immortality of his writings, it was natural the emperor should cultivate the good will and seek to secure the "deathless meed" of his favourite's song. That Horace had fought with Brutus against him was no prejudice. To have espoused the cause, and enjoyed the confidence of one whose nobility of purpose his adversaries never scrupled to acknowledge, formed, indeed, in itself a claim upon his successful rival's esteem. Horace was no renegade; he was not ashamed of the past, and Mæcenas and Augustus were just the men to respect him for his independence, and to like him the better for it. They could appreciate his superiority to the herd of parasites and time-servers around them; and like all the greatest actors on the political stage, they were above the petty rancours of party jealousy, or the desire to enforce a renunciation of convictions opposite to their own. It was by never stooping to them unduly that Horace secured their esteem, and maintained himself upon a footing of equality with them, as nearly as the difference of rank would allow. There is no reason to suspect Horace, in the praises which he has recorded of Augustus, either of insincerity or sycophancy. He was able to contrast the comparative security of life and property, the absence of political turmoil, and the development of social ease and happiness, which his country enjoyed under the masterly administration of Augustus, with the disquietude and strife under which it had languished for so many years. The days of a republic had gone by, and an enlightened despotism must have been welcomed by a country shaken by a long period of civil commotion, and sick of seeing itself played for as the stake of reckless and ambitious men. He was near enough to the councils of the world's master to see his motives and to appreciate his policy; and his intimate personal intercourse with both Augustus and Mæcenas no doubt enabled him to do fuller justice both to their intentions and their capacity, than was possible perhaps to any other man of his time. The envy which his intimacy with these two foremost men of all the world for a time excited in Roman society by degrees gave way, as years advanced, and the causes of their esteem came to be better understood. Their favour did not spoil him. He was ever the same kindly, urbane, and simple man of letters he had originally been. He never presumed upon his position, or looked superciliously on others less favoured than himself. At all times generous and genial, years only mellowed his wisdom, and gave a sharper lustre to the beauty of his verse. The unaffected sincerity of his nature, and the rich vein of his genius, made him courted by the rich and noble. (*Odes*, ii. xvii., 9, *et seq.*) He mixed on easy terms with the choicest society of Rome, and what a society must that have been which included Virgil, Varius, Plotius, Tibullus, Pollio, and a host of others, who were not only ripe scholars, but had borne and were bearing a leading part in the great actions and events of that memorable epoch? It is to this period that the composition of his principal odes is to be attributed. To these, of all his writings, Horace himself ascribed the greatest value, and on these he rested his claims to posthumous fame. They were the result of great labour, as he himself indicates: "Operosa parvus Carmina fingo" (*Odes*, IV. ii., 31), and yet they bear pre-eminently the charm of simplicity and ease. He was the first to mould the Latin tongue to the Greek lyric measures; and his success in this difficult task may be estimated from the fact, that as he was the first so was he the greatest of the Roman lyrists. Quinctilian's criticism upon him can scarcely be improved: "Lyricorum Horatius fere solus legi dignus. Nam et insurgit aliquando, et plenus est jucunditatis et gratiæ, et variis figuris, et verbis felicissime audax." In this airy and playful grace, in happy epithets, in variety of imagery, and exquisite felicity of expression, the *Odes* are still unsurpassed among the writings of any period or language. If they want the inspiration of a great motive, or the fervour and resonance of the finest lyrics of Greece, they possess at all events an exquisite grace and terseness of expression, a power of painting an image or expressing a thought in the fewest and fittest words, and a melody of tone, which imbue them with a charm quite peculiar, and have given them a hold upon the minds of educated men, which no change of taste has shaken. That they are inferior to his Greek models is not to be wondered at. Even although Horace had possessed the genius of Pindar or Sappho, it is doubtful whether, writing as he did in an artificial language, which he was compelled to make more artificial by the adoption of Grecian terms of expression, and being therefore without the free and genial medium of expression which they had at command, he could have found an adequate utterance for his inspiration. But his genius was akin to neither of these; and that good sense, which is his great characteristic, withheld him from ever either soaring too high or attempting to sustain his flight too long. He knew the measure of his powers, and in his greatest efforts therefore no undue strain upon them is to be detected. His power of passion is limited, and his strokes of pathos are few and slight. Above all, he did not possess the faculty, which, in a lyrical writer, is the highest, of losing himself in a great theme. Whatever subject he treats, we never lose sight of the poet in the poem. This quality, while it is fatal to lyric poetry of the highest class, helps, however, to heighten the charm of the mass of his odes, especially those which are devoted to his friends, or which breathe the delight with which the contact with the ever fresh beauties of natural scenery inspired him. Into these he throws his whole heart, and in them we feel the fascination which made him beloved by those who came within the circle of his personal influence, and which makes him as it were the well known and intimate friend of all to whom his writings are a familiar study. Horace was not and could not have been a national poet. He wrote only for cultivated men, and under the shadow of a court. The very language in which he wrote must have been unintelligible to the people, and he had none of those popular sympathies which inspire the lyrics of Burns or Béranger. The Roman populace of his time was perhaps as little likely to command his respect as any which the world has ever seen; and there was no *people*, in the sense in which we understand the word, to appeal to. And yet Horace has many points in common with Burns. "A man's a man for a' that," in the whole vein of its sentiment is thoroughly Horatian; but the glow which kindles the heart and fires the brain is subdued to a temperate heat in the gentler and physically less energetic nature of Horace. In his amatory verses the same distinction is visible. None of his erotic poems are vivified by those gushes of emotion which animate the love poetry of the poets we have named and of other modern song writers. Never indeed was love less ideal or intense in a poet of unquestionable power. Horace is not insensible to beauty. No writer hits off with greater neatness the portrait of a beauty, or conjures up more skilfully before his reader an image of seductive grace. But the fire of genuine passion is wanting. Horace's ardour seems never to have risen above the transient flush of desire. His heart is whole though Cupid may have clapped him on the shoulder. The Lalages and Lyces, the Glyceras and Phrynes of his *Odes* are pretty playthings of an hour, who amused his fancy and delighted his senses, but never robbed him of a night's repose or of a day's appetite. The attempt to make them out as real objects of attachment is one of the many follies in which his commentators have wasted much dreary labour. Horace might, no doubt, have sung of himself, like Béranger, in his youth,—

> "J'avais vingt ans une folle maitresse,
> Des francs amis, et l'amour de chansons,"—

and even when he could count eight lustres, despite his own protest (*Ode* ii., 4, 21, *et seq.*), his senses were probably not dead to the attractions of a fine ancle, or a pretty face, or to the fascination of a sweet smile, or a musical voice. But his passions were too well controlled, and his love of ease too strong, to have admitted of so many flirtations as would be implied in the supposition that Tyndaris, Myrtale, and a score of others, were actual favourites of the bard. To sing of beauty has always been the poet's privilege and delight; and to record the lover's pains an easy and popular theme. Horace, the wit and friend of wits, was not likely to be out of the mode, and so he sang of love and beauty according to his fashion. Very airy and playful and pleasant is that fashion, and, for his time, in the main comparatively pure and chaste; but we seek in vain for the tenderness, the negation of self, and the pathos, which are the soul of all true love poetry. "His love ditties," it has been well said, "are, as it were, like flowers, beautiful in form, and rich in hues, but without the scent that breathes to the heart." It is certain that many of them are merely imitations of Greek originals.

His *Satires* and *Epistles* are less read, yet they are perhaps intrinsically more valuable than his lyric poetry. They are of very various merit, written at different periods of his life, and, although the order of their composition may be difficult to define with certainty, much may be inferred, even from the internal evidence of style and subject, as to the development of the poet's genius. This subject has engaged much of the attention of the commentators, and all concur in placing the *Satires* first, and the *Epistles*, including the *Epistle to the Pisos, De Arte Poeticâ*, last in the order of date. As reflecting "the age and body of the time," they possess the highest historical value. Through them the modern scholar is able to form a clearer idea of the state of society in Rome in the Augustan age than of any other phase of social development in the history of nations. Mingling, as he did, freely with men of all ranks and passions, and himself untouched by the ambition of wealth or influence which absorbed them in the struggle of society, he enjoyed the best of opportunities for observation, and he used them diligently. Horace's observation of character is subtle and exact, his knowledge of the heart is profound, his power of graphic delineation great. A genial humour plays over his verses, and a kindly wisdom dignifies them. Never were the maxims of social prudence and practical good sense inculcated in so pleasing a form as in the *Epistles*. The vein of his satire is delicate yet racy, and he stimulates and amuses, but rarely offends by indelicacy, or outrages by coarseness. He does not spare himself upon occasion. His sarcasms, moreover, have no spice of malignity, neither are they tinged by the satirist's vice of vaunting his superiority to his neighbours. For fierceness of invective, or loftiness of moral tone, he is inferior to Juvenal; but the vices of his time were less calculated to provoke the "sæva indignatio," or to call for the stern moral censure of the satirist of a more recent date. He deals rather with the weakness and follies, than with the vices or crimes of mankind, and his appeals are directed to their judgment and practical sense rather than to their conscience. The idea of duty or absolute right is not a prominent one with Horace. He inculcates what is fitting and decorous, and tends most to tranquillity of mind and body, rather than the severe virtues of a high standard of moral purity. To live at peace with the world, to shun the extremes of avarice, luxury, and ambition, to outrage none of the laws of nature, to enjoy life wisely, and not to load it with cares which the lapse of a few brief years will demonstrate to be foolishness, is very nearly the sum of his philosophy. Of religion, as we understand it, he had little. He was, however, too observant of the world around him, and too habitually accustomed to look into his own soul, not to have been profoundly impressed with the evidences of Supreme Wisdom governing the machine of the universe, and to have felt aspirations for a future in which the mysteries of the present world should find a solution. Although himself little of a practical worshipper—*parcus deorum cultor et infrequens*—he respected the sincerity of others in their belief in the old gods. But in common with the more vigorous intellects of the time, he had outgrown the effete creed of his countrymen. He could not accept the mythology, about which the forms of the contemporary worship still clustered. The relation of the universe to its Maker was a mystery to him, and the agency of an active Providence, if it occasionally startled him out of the easy indifference of a vain philosophy, seems to have been by no means a permanent conviction of his mind, influencing his actions, or giving a lofty sweep to his speculations. The morality of enlightened and far-seeing wisdom was attainable by such a mind, and it was attained; but to the divine spirit, which raised some of the ancient writers almost to a level with the inspired authors of the books of our faith, Horace has no claim. As a living and brilliant commentary on life, as a storehouse of maxims of practical wisdom, couched in language the most apt and concise, as sketches of men and manners, which will be always fresh and always true, because they were true once, and because human nature will always reproduce itself under analogous circumstances, his *Satires*, and still more his *Epistles*, will have a permanent value for mankind. In these, too, as in his *Odes*, Horace helped materially in giving to the Latin language the highest amount of polish of which it is susceptible.

At no time very robust, Horace's health appears to have declined for some years before his death. He was doomed to see some of his most valued friends drop into the grave before him. This to him, who gave to friendship the ardour which other men give to love, was the severest wound that time could bring. Youth, and spirits, and health, the inevitable decay of nature, saddened the thoughtful poet in his solitude, and tinged the gayest society with melancholy. But the loss of friends, the brothers of his soul, of Virgil, Quinctilius, Tibullus, and others, and ultimately of Mæcenas, without that hope of reunion which springs from the cheering faith which was soon afterwards to be revealed to the world, must have by degrees stripped life of most of its charms. *Singula de nobis anni prædantur euntes* (*Epis.* II. ii., 55) is a cheerless reflection to the man who has no assured hope beyond the present time. Mæcenas's health was a source of deep anxiety to him, and one of the most exquisite odes (the 17th of the 2d book), addressed to him, in answer to some outburst of despondency, while it expresses the depth of the poet's regard, bears in it the tone of a man somewhat weary of the world:—

> "Ah! if untimely fate should snatch thee hence,
>   Thee, of my soul a part,
> Why should I linger on, with deaden'd sense,
>   And ever-aching heart,
> A worthless fragment of a fallen shrine?
> No, no! One day beholds thy death and mine!
>
> "Think not that I have sworn a bootless oath!
>   Yes, we shall go, shall go,
> Hand link'd in hand, whene'er thou leadest, both
>   The last sad road below!"

The prophecy seems to have been realized almost to the letter. The same year (A.U.C. 746, B.C. 8) witnessed the death of both Horace and Mæcenas. The latter died in the middle of the year, bequeathing his friend, in almost his last words, to the care of Augustus: *Horatii Flacci, ut mei, esto memor.* On the 27th of November, when he was on the eve of completing his fifty-seventh year, Horace himself died, of an illness so sharp and sudden, that he was unable to make his will in writing. He declared it verbally before witnesses, leaving the little all which he possessed to Augustus. He was buried on the Esquiline Hill, near his patron and friend Mæcenas. No trace of the tombs of either remains; but the name and fame of both are inextricably entwined, and can only perish with the decay of literature itself. The fame of Horace was at once established. In the days of Juvenal he shared with Virgil the doubtful honour of being a schoolbook (Juvenal, *Sat.* vii. 226). That honour he still enjoys; but it is only by minds matured by experience and reflection that Horace can be thoroughly appreciated. To them the depth of his observation, and the reach of his good sense are made daily more apparent; and the verses which charmed their fancy or delighted their ear in youth, became the counsellors of their manhood, or the mirror which focalizes for their old age the gathered wisdom of a lifetime. No writer is so often quoted, and simply because the thoughts of none are more pertinent to men's "business and bosoms" in the concerns of every-day life, amid the jostle of a crowded and artificial state of society; and because the glimpses of nature, in which his writings abound, come with the freshness of truth, alike to the jaded dweller in cities, and to those who can test them day by day in the presence of nature herself. To Petrarch and Wordsworth he was a favourite study. Richard Hooker made him a manual. Louis XVIII. had him by heart; and there is scarcely a statesman of eminence in whose mouth his sayings are not household words.

There are no authentic busts or medallions of Horace, and his descriptions of himself are vague. He was short in stature; his eyes and hair were dark, but the latter was early silvered with gray. He suffered at one time from an affection of the eyes, and seems to have been by no means robust in constitution. His habits were temperate and frugal, as a rule, although he was far from insensible to the charms of a good table and good wine, heightening and heightened by the zest of good company. But he seems to have had neither the stomach nor the taste for habitual indulgence in the pleasures of the table. In youth he was hasty and choleric, but easily placable; and to the last he probably shared in some degree the irritability which he ascribes to his class. At the same time, if his writings be any index to his mind, his temper was habitually sweet and well under control. Like all playful men, a tinge of melancholy coloured his life, if that is to be called melancholy which is more properly only that sense of the incompleteness and insufficiency of life for the desires of the soul, which must be deeply seated in all earnest natures. Latterly he became corpulent, and sensitive to the severity of the seasons, and sought at Baiæ and Tivoli the refreshment or shelter which his mountain retreat had ceased to yield to his delicate frame.

The chronology of the poems of Horace has been the source of much critical controversy. The earlier labours of Bentley, Masson, Dacier, and Sanadon have been followed up in modern times by those of Passow, Walckenaer, Weber, Grotefend, and Stallbaum abroad, and of Tate and Milman at home. As the subject is not one which admits of certainty, the speculation is endless, and must always be in a great measure unsatisfactory. The general result may be stated as follows. The *Satires* and *Epodes* were first in the order of composition, having been written between the years 713 and 725, after the return of Horace to Rome, and before the close of the civil wars consequent upon the defeat of Antony and his party. The two first books of *Odes* appeared between this period and the year 730. Then followed the first book of *Epistles.* The third book of *Odes* appears to have been composed about the year 735, the *Carmen Seculare* in 737, and the fourth book of *Odes* between 737 and 741. The second book of *Epistles* may be assigned to the period between 741 and 746; and to the same period may be ascribed the composition of the *Epistle to the Pisos.* The results of the speculations of Bentley and several of the leading critics are presented in a tabular form in the admirable edition of *Horace* published by Firmin Didot, Paris, 1855, with the commentary of Dübner, which is a model at once of typographical beauty and editorial skill.

For a list of the best editions of *Horace*, and of the numerous works on the topography and chronology of his poems, reference may be made to Smith's *Dictionary of Greek and Roman Biography and Mythology*, London, 1850, *sub voce* Horatius.

The translations of *Horace* into all the European languages are numerous. The English versions are more numerous than successful. Pope and Swift, in their imitations, have caught more of his manner than any of the translators: and probably the rendering which will convey the best idea of his peculiar charm will be that which hits a happy medium between the literal and the paraphrastic. The translation of Francis, which long held a place as the English representative of this classic, is a poor performance, and is rapidly falling into merited oblivion. That of Wrangham is weak, colourless, and trivial. Of late years many versions have issued from the press, among which those of F. W. Newman, London, 1853; Melville, London, 1850; and Robinson, London, 1846-55, are chiefly remarkable. But a good English *Horace* is still a desideratum, and, if ever supplied, it will probably be the result of the combined labours of many hands. (T. M—N.)

HORIZON (ὁριζω, *I bound*), the plane of a great circle which divides the upper or visible from the lower or invisible hemisphere. See ASTRONOMY; and GEOGRAPHY.

HORN. The projecting weapons on the head of the ox, the sheep, the antelope, and the rhinoceros, consist of a sheath of horn on a core of bone. Horn is composed chiefly of coagulated albumen, gelatine, and a small portion of phosphate of lime. It is essentially distinct from bone and ivory; the antlers of the stag, although sometimes called horns, consist entirely of bone. Modifications of horn may be noticed in the scales of the armadillo, the plate armour of the tortoise, the spines of the porcupine and hedgehog, the quills of birds, and the hoofs, claws, and nails, of animals. For manufacturing purposes, the horns and hoofs of the bull and cow are in request, and there is a large import of these from South America, Southern Africa, and from Russia. The horns of the bison and buffalo, the chamois and the antelope, are used for the better kinds of work.

The manufacturer first detaches the horn from the bony core, by macerating the horn in water for a month or six weeks, when the membrane by which the horn is attached to the core putrifies and allows the two to be separated. The ash of the cores makes excellent cupels for the assay of gold and silver. The solid tips of the horn are sawn off, and are used for handles for knives, for buttons, &c.; the other portion of the horn is cut into short lengths, or soaked whole in boiling water, or heated at a fire, the effect of which is to soften it, and allow it to be spread out nearly flat. The *flats* are next pressed between warm and greased iron plates, the pressure varying according to circumstances. If intended for lanterns, the pressure is continued until the horn separates into distinct plates; these are placed on a board covered with hide, and scraped with a knife having a wire edge. Some of the shavings which come off are sometimes dyed and cut into various forms, and are so sensitive as to curl up by the warmth of the hand. They are sold at toy-shops under the name of "sensitive leaves." After the scraping, the sheets of horn are polished with a woollen cloth dipped in charcoal dust and water, next with rotten-stone, and lastly with horn shavings.

The effect of heat and pressure on light-coloured horn is to render it transparent; but most of the articles made of horn are coloured artificially by boiling the horn in infusions of colouring matter. If the horn be intended for combs, the pressure must be moderated, or the teeth will be brittle; if intended for drinking cups, the horn is cut into lengths, scalded, roasted, and moulded in a cone of wood, and a wooden plug is driven into it for pressing the horn into the required shape. After this, the cup is turned and polished at the lathe, and a groove is cut to receive the bottom; this is cut out of a flat piece of horn by means of a crown saw, and the bottom of the cup having been softened at the fire, the disk is forced into the groove, and the horn contracting in cooling makes a water-tight joint. For knife-handles and similar works, the horn is cut nearly to the required form, and is moulded in dies with the assistance of heat and a powerful screw-press. The work is finished by scraping and buffing with Trent sand and oil, or rotten-stone and oil. Horn is sometimes used as a vehicle for applying polishing powders to the flat works of the watchmaker. In the Great Exhibition of 1851, there were sundry small articles of chamois horn, consisting of brooches, shirt-buttons, rings, and watch-keys, by a Swiss exhibitor; there were also some transparent horn paintings from Hamburg, and a pair of polished ox-horns from Port Natal, with the head complete, measuring from tip to tip 8 ft. 4 in., and 21 in. in circumference. The best collection of articles in horn-work was, however, from Turkey. See TORTOISE-SHELL. (C. T.)

HORN, a musical instrument, varying in form and in quality of sound. Each horn has a cup-shaped mouth-piece, by blowing into which, with a particular management of the lips, the sounds are produced. The ancient coronets, of different sizes, straight-shaped, formed of wood, &c., need not be described here, as they are disused. The common hunting-horn is of copper or brass, and bent into a semicircle. The French horn is made of brass, and consists of a tube bent into circular convolutions, and terminating in an expansion of the tube, called the bell or pavilion. There are generally two French horns used in orchestras, or in military bands,—a first and a second horn,—and these are furnished with crooks which alter the length of the tube, so as to adapt the horns to the different keys of the music to be played. The natural or open sounds follow the harmonic progression 1, 2, 3, 4, 5, 6, 7, &c.; but by placing the hand, or a cone of pasteboard, within the bell, the intermediate tones and semitones may be produced, and a scale formed, more or less pure and accurate. (See MUSIC, § *Horn.*) Finger-keys were at one time applied to some horns, but have been superseded by pistons. The old bugle-horn is now the pistoned cornet or cornopean. Of late years, C. J. Sax of Brussels has greatly improved all instruments of the horn kind, as well as flutes, clarinets, &c. The German bass-horns are made of wood, and have finger-holes and finger-keys. The basset-horn and the English horn are not really horns, the former being only a large clarinet, and the latter a large oboe, with some peculiarities of form. See Appendix to G. F. Graham's *Essay on Musical Composition*, Edin. 1838.

HORN, or *Hoorn, Cape*, commonly considered the southern extremity of America, is not a part of that continent, but the most southerly point of a small island of the Tierra del Fuego group; S. Lat. 56. 58. 40., W. Long. 67. 16. It consists of a lofty, precipitous, bare black rock, running far out into the sea; and was formerly considered dangerous to pass on account of the strong westerly gales that prevail in its neighbourhood during summer, but as these are restricted to the vicinity of the cape, vessels avoid the difficulty by sailing in a higher latitude. It was discovered in 1616 by the Dutch navigator Schouten, who named it after his native town, Hoorn.

HORNCASTLE, a market-town of England, county of Lincoln, on the Bain, a tributary of Witham, and navigable to this point, 18 miles E.S.E. of Lincoln. It was anciently a Roman station, and traces of its old walls still exist. Roman coins and other antiquities have also been discovered in the vicinity. A considerable trade is carried on by means of the river. Horncastle has a grammar school, mechanics' institute, library, literary society, and a savings bank. The market-day is Saturday; and one of the largest horse fairs in the kingdom is held here in August. Pop. (1851) 4921.

HORNE, GEORGE, author of the *Commentary on the Psalms*, was born in 1730 at Otham, in Kent. He was educated in the school of Maidstone, whence he passed to University College, Oxford. He afterwards became a fellow, and finally principal of Magdalen College. In 1771 he was chosen chaplain-in-ordinary to the king, and held that office for ten years. In 1776 he became vice-chancellor of the University; five years later, he was made dean of Canterbury; and in 1790 was promoted to the see of Norwich, which he retained till his death, Jan. 17, 1792.

Bishop Horne's only important work, his *Commentary on the Psalms*, exhibits a deep acquaintance with Hebrew and biblical lore, and is marked by a spirit of earnest piety. It has been frequently reprinted, and still retains its ground. His other works, for the most part fugitive pieces of a controversial character, are now forgotten. The best of them were written to defend the views of Hutchinson as against those of Sir Isaac Newton; which latter, until he understood them thoroughly, he at first believed were designed to subvert the theology of Scripture.

HORNER, FRANCIS, was born at Edinburgh Aug. 12, 1778. His father was a merchant in that city, of sufficient wealth to give him the best education that money could at that time procure in Scotland. After passing through the ordinary courses at the High School and University of Edinburgh, he qualified himself for the bar, and began to practise with very reasonable prospects of success. His native city, however, he found too small a field for his high aspirations and wide views, and accordingly he removed in 1802 to London, where he entered himself of Lincoln's Inn, hoping to find his true sphere in Westminster Hall. The interval that elapsed between this date and his admission to the English bar in 1807, he spent in a most comprehensive course of legal and general study; and his papers in the *Edinburgh Review* (chiefly on subjects connected with political economy) attest the extent and variety of his reading, and the largeness and soundness of his views. Entering parliament in 1806 for St Ives in Cornwall, and in 1813 for St Mawes, he allied himself with the Whigs, and fixed the attention of England by the ability with which he discussed all the questions of political economy and finance that came before the house. On the question of freedom of trade, especially in corn, he displayed the wisdom of a philosopher, and the knowledge and foresight of a practical statesman, and anticipated by nearly half a century the principles that now regulate the commerce of Great Britain. Perhaps his crowning achievement in parliament was the part he took in the great Bullion question. He was a member of the Bullion committee, and drew up the first part of the report; and it was mainly through his exertions that the unlimited issue of paper-money by the Bank of England and the private banks of the country was stopped, and gold and silver re-established as the only legal circulating media. His parliamentary and literary labours, prosecuted with noble and disinterested zeal for many years, at length wore out a frame naturally far from robust; and in 1816, having gone to Italy in the hope of recruiting his shattered health, he died at Pisa, Feb. 8, 1817.

The most striking characteristic of Horner's mind was its comprehensiveness, a quality which shows itself as remarkably in the plan of private study which he drew up for his own guidance, while only on the threshold of manhood, as in his matured parliamentary efforts. His independence of character was shown in his adoption and manful support of a political creed, which in his early youth it was almost dangerous to profess in Scotland. In choosing this creed he was influenced neither by prejudice nor by passion, but by a simple love of what seemed to him to be the truth, and throughout life he always sought after truth for its own sake, wherever it was to be found. Few Britons of this century have gone to the grave so sincerely and so generally lamented as Horner, if we except Sir Robert Peel. His countrymen found in him a safe and powerful man, who was labouring not for himself or his party but for them. "They were convinced of his talents, they confided in his moderation, and they were sure of his motives; he had improved so quickly and so much that his early death was looked on as the destruction of a great statesman who had done but a small part of the good which might be expected from him, who would infallibly have risen to the highest offices, and as infallibly have filled them to the public good." On his private character it is hardly necessary to dilate. Integrity, gentleness, and nobility of nature are accorded to him by all that ever knew him, without one dissenting voice. Sidney Smith said of him, "the commandments were written on his face, and I have often told him there was not a crime he might not commit with impunity, as no judge or jury who saw him would ever give the smallest degree of credit to any evidence against him; there was in his look a calm settled love of all that was good and honourable—an air of wisdom and of sweetness; you saw at once that he was a great man, whom nature had intended for a leader of human beings; you ranged yourself willingly under his banners, and cheerfully submitted to his sway" (*Memoirs of Francis Horner, with Selections from his Correspondence*, Lond. 1843).

HORROCKS, or HORROX, JEREMIAH, born 1619, at Liverpool, died 1641. See Fourth Preliminary DISSERTATION.

HORSE.

THE Horse is a distinct genus belonging to the order of *Pachydermata*, Cuv., and in himself the most serviceable of all quadruped animals, and ranks with the greyhound as the swiftest of those brought under the dominion of man. Notwithstanding these high qualifications, ancient history informs us that in the primitive ages of the world the ass was used in preference to him, not only as a mere beast of burthen, but for the purpose of conveying from place to place persons of the highest distinction. This, however, may be satisfactorily accounted for. Previously to the art of horsemanship being known, the ass, a superior race of animal perhaps to that generally found in Europe, was more easily managed than the horse, and better suited to the kind of food usually met with for his support. He was, in fact, found to answer every purpose of horses, until mankind increased in numbers and in wealth, when the complicated interests that were the result brought their services into use, and they were trained to the art of war. But another reason may be given for the late introduction of horses. Their use was interdicted by the Almighty in the early ages of the world; first, lest his favourite people, the Israelites, should be led to idolatry by carrying on commerce with Egypt; secondly, by their dependence on a well-appointed cavalry, they might cease to trust in the promised aid of Jehovah; and, thirdly, that they might not be tempted to extend their dominion by such means, and then, by mixing with idolatrous nations, cease in time to be that distinct and separate people which it was His intention they should be, and without which the prophecies relative to the Messiah could not be fully accomplished. Thus, in the Book of Psalms, the horse commonly appears only on the side of the enemies of God's people; and so entirely unaccustomed to the management of him were the Israelites at the period of their signal defeat of the Philistines and other idolatrous nations, that David, their commander and king, caused the greater part of the horses of the cavalry prisoners to be cut down. In the reign of Solomon, however, a cavalry force was established, but to no great extent.

In the infant state of all nations, indeed, we can readily account for the restrictive use of horses. A great deal of land that might be applied to the production of human food is requisite for their maintenance in all countries; and, in hot and sterile ones, the camel answered better, and was found ready at hand. It is true they were used in the armies of the ancient Greeks and Romans, which were not considered as complete without them. In Greece they were not so numerous; but in a war with the Italic Gauls the Romans are said to have had no less than 70,000 horse and 700,000 foot to attack their formidable enemies. The army of Xerxes, when reviewed by him at Dorsica, in Thrace, after it had passed the Hellespont, is reported by Herodotus, contemporary with him, to have contained 80,000 horse; but the judicious reader will be inclined to make considerable abatements from the boasted amount of that celebrated but ill-fated expedition, resting, as it does, entirely on the authority of Grecian writers, who represented facts in the light the most unfavourable to their enemies, and the most glorious to their own gallant countrymen.

As in the scale of excellence the horse ranks first of all animals coming under the denomination of cattle, and, as

Buffon justly says of him, "possesses, along with grandeur of stature, the greatest elegance and proportion of parts of all quadrupeds," it is not a matter of surprise that, as an image of motive vigour, he should have been the subject of the chisel and the pencil of the first artists in the world, or that the description of him by the pen should have been not considered as unworthy the greatest writers of antiquity. But it is only in his native simplicity, in those wild and extensive plains where he was originally produced, that we can form an adequate idea of this noble animal. It is here that he disdains the assistance of man, which only tends to servitude; and it is to a description of his release from this servitude, his regaining his natural liberty, that we are indebted for two of the finest similes of the immortal Greek and Roman epic bards. The return of Paris, with Hector, to the battle of Troy, is thus given in the sixth book of the *Iliad*:—

> "Ως, δ᾽ ὅτε τις στατὸς ἵππος, ἀκοστήσας ἐπὶ φάτνη,
> Δεσμὸν ἀποῤῥήξας θείῃ πεδίοιο κροαίνων,
> Εἰωθὼς λούεσθαι ἐϋῤῥεῖος ποταμοῖο,
> Κυδιόων· ὑψοῦ δὲ κάρη ἔχει, ἀμφὶ δὲ χαῖται
> Ὤμοις ἀΐσσονται· ὁ δ᾽ ἀγλαΐηφι πεποιθώς,
> Ῥίμφα ἑ γοῦνα φέρει μετά τ᾽ ἤθεα καὶ νομὸν ἵππων."

And Virgil is considered to have even exceeded Homer in that splendid passage in the eleventh book of the *Æneid*, where Turnus, turning out fully accoutred for the fight, is compared to a horse that has just broken loose from his stall:—

> "Qualis, ubi abruptis fugit præsepia vinclis,
> Tandem liber equus, campoque potitus aperto,
> Aut ille in pastus armentaque tendit equarum,
> Aut, assuetus aquæ perfundi flumine noto,
> Emicat, arrectisque fremit cervicibus alte
> Luxurians; luduntque jubæ per colla, per armos."

It is impossible, at this distance of time, to fix upon the native country of the horse, as he has been found in various forms and of various sizes in every region of the Old World. The difference in size is easily accounted for. The origin of all animals of the same species was doubtless the same in the beginning of time, and it is chiefly *climate* that has produced the change we perceive in them. Warmth being congenial to his constitution, and cold naturally injurious to him, he is produced in the most perfect form, and in the greatest vigour, when subject to the influence of the one, and not only diminutive, but misshapen and comparatively worthless, when exposed to the evils of the other. Buffon, however, is wrong in making the horse indigenous to Arabia, as is clearly proved by a reference to the Sacred Writings. In the reign of Saul horse-breeding had not yet been introduced into Arabia; for, in a war with some of the Arabian nations, the Israelites got plunder in camels, sheep, and asses, but still no horses. Even at the time when Jerusalem was conquered and first destroyed by Nebuchadnezzar, Arabia appears to have been without horses, as the Tyrians brought theirs from Armenia. That the earliest available uses of the active powers of horses was adopted by the Egyptians, the same authority satisfies us; for we read in the third chapter of Genesis that when Joseph carried his father's remains from Egypt to Canaan "there went up with him both chariots and horsemen." About 150 years afterwards, the horse constituted the principal strength of the Egyptian army; Pharaoh having pursued the Israelites with "six hundred chosen chariots, and with all the chariots of Egypt." The earliest period now alluded to was 1650 years before the birth of Christ; and 1450 years before that event, the horse was so far naturalized in Greece that the Olympic Games were instituted, including chariot and horse races.

The origin of the native horse of our own country is now merely a question of historical interest, the discussion of which would not lead to much practical benefit. That experiments, founded on the study of his nature and properties, which have from time to time been made to improve the breed, and bring the different varieties to the perfection in which we now find them, have succeeded, is best confirmed by the fact of the high estimation in which the horses of Great Britain are held in all parts of the civilized world; and it is not too much to assert that, although the cold, humid, and variable nature of our climate, is by no means favourable to the production of these animals *in their very best form*, we have, by great care, and by our attention to breeding, high feeding, and good grooming, with consequent development of the muscles, brought them to the highest state of perfection of which their nature is susceptible. They may be classed under the following heads, and treated of individually, viz., the race-horse; the hunter; the hackney, for various purposes; the charger; the troop horse; the coach, chariot, and gig horse; and the draught or cart horse.

THE RACE-HORSE.

Although we may safely pronounce that the native breed of English horses, however esteemed for other purposes, could not *race*, in the present acceptation of that word, yet it is equally obvious that they formed the parent stock of the renowned English racer. The first step to improve it by a cross with Eastern blood appears to have been taken by James I., who gave the enormous sum (in those days) of L.500 for an Arab stallion, which, however, the Duke of Newcastle, in his work on horsemanship (great authority at that time), wrote down on account, chiefly, of his comparatively diminutive size. At the Restoration, however, there appears to have been a tolerably good breed of horses in England, which Charles II. improved by an importation of Barbs and Turks, whose blood was engrafted on the original stock, already very considerably ameliorated by the services of a stallion called Place's White Turk (imported by Oliver Cromwell's Master of the Horse, who bore that name), and afterwards by those of the Helmsley Turk, followed by Fairfax's Morocco Barb. The change was at this time so visible, that the Lord Harleigh of that day expressed his fears lest it might be carried to such an extreme as to extirpate the strong and useful horse, which, perhaps, the majority of his countrymen were well satisfied with before. In the latter end of Queen Anne's reign, however, the first great trump turned up to secure future success. This was a stallion called Darley's Arabian, purchased in the Levant by a Yorkshire merchant of that name, although without any real attestation of his pedigree or country. The prejudice against Arabians and other eastern horses, the effect of the Duke of Newcastle's anathema against them, having now for the most part subsided, a good deal of their blood had been infused into the mares of that day, when another stallion, whose services were still more signal, accidentally made his appearance. We allude to the Godolphin Arabian, as he was called, purchased out of a cart in Paris, and consequently of uncertain caste, but evidently the horse of the desert; who, as will be hereafter shown, may be said to have won the game. Although at first thought so meanly of as only to be used as a teazer, yet, fortunately for the turf, he lived twenty years after his services became notorious by the accident of his being the sire of a capital racer out of a mare which the stallion to which he was teazer refused to cover; and, strange to say, no very superior race-horse has appeared in England for many years that cannot be traced to his blood. The success of this horse was much facilitated by the lucky coincidence of his arrival in England at a critical time; that is to say, when the stock from Darley's horse, and the several Arabs, Barbs, and Turks, together with the royal mares imported by Charles II. had been "crossed" (as the term is) on each other, and had produced mares worthy to be the channel of imparting his own transcendant qualities to posterity. Taking it for granted, then, that the English race-horse is descended from Arabian, Turkish, and African (Barb) blood; and also taking into consideration the various peculiarities in the form and power of each of those kinds, requiring modification of shape, qualities, and action suited to the purposes for which they were intended, it cannot be denied that a task of no ordinary difficulty was imposed on the English horse-breeders, and that they have executed that task with a masterly hand. If other countries furnished the blood, England has made the race-horse.

With the exception of one Eastern horse, called the Wellesley Arabian, the grandsire of a winner of the Oaks in 1826, also of Dandizette, who ran second for that stake in 1823, and one or two more good runners, the English turf has benefited nothing during the last three-quarters of a century from the importation of foreign blood. The fact is, that having once gotten possession of the essential constitutional parts necessary to form the race-horse (and which will be described hereafter), we ourselves have (by a superior knowledge of the animal and the means of availing ourselves of his capabilities, not only by rearing and training, but by riding him also) brought him to a pitch of excellence which will not admit of further improvement. Superior as is the air of the desert (which is said to be so free from vapours that the brightest steel is not affected with rust if exposed to it for a night) to that of our humid and ever-varying climate, which, especially in Ireland, is said to produce blindness in horses; and propitious as it must be to animals found, *as the horse was found*, in the greatest perfection when reared in it; yet were the finest Eastern horse that could be procured brought to the starting-post at Newmarket, with the advantage of English training to boot, he would have no chance, at any weight or for any distance, with even a second-rate English race-horse. They will not bear what jockeys term "squeezing" in the last fifty yards of a race, and lose all heart in an instant. The late Mr Atwood was the last racing man who ran half-bred Arabs in England, and he scarcely ever won a race with them from this cause.

Although we have spoken in disparagement of horses of the East as racers, upon the same terms with those of our own breeding, we are willing to allow them the merit of being the parent stock of all our racing blood; as it is quite evident the indigenæ of our own country, or of those European ones which approximate to it, would never have produced the sort of race-horse now seen on the British turf. The nature and character, indeed, of the horse of the desert, are peculiarly adapted to an animal which, like the race-horse, is called upon to put its physical powers to the severest test to which nature, aided by art, can submit. In the first place, the Arabian horse possesses a firmness of leg and sinew unequalled by any other in the world. This excellence, which he owes to climate, arises from his having larger muscles and *smaller bone* than other horses have; muscles and sinews being the sole powers of acting, and on them depend the lasting qualities of an animal going at the top of his speed. Bones being the weight to be lifted, serve only to extend the parts; and it is evident that such as are small but highly condensed, like those of the deer and the horse of the desert, are, by occupying less space and containing less weight, more easily acted upon by muscular force than such as are large and porous, and for a greater duration of time, without fatiguing the acting powers. But the excellence of the Arabian horse, or horse of the desert, does not end with his highly condensed bone, and flat and wiry leg, so much esteemed by the sportsman. All the muscles and fibres of his frame are driven into closer contact than those of any other breed; and, by the membranes and ligaments being composed of a finer and thinner substance, he possesses the rare quality of union of strength with lightness, so essential to the endurance of fatigue in all quick motions. He thus moves quicker and with more force, by reason of the lightness and solidity of the materials of which his frame is composed; and when to these qualifications are added the peculiar and deer-like elegance of his form, and extraordinary share of muscular power for his inches, he appears to furnish all the requisites of the race-horse on a small scale.

It is worth inquiring into the reason of the improvement of the horse of the desert, and indeed of all the countries of the East, not advancing towards perfection, as that of our own breed has done. No doubt it was intended that we should improve upon animal nature as we improve our own, and nowhere has the attempt been so successful as upon our varieties of domestic cattle; but the horse of the desert now, if he has not retrograded in his good qualities, is the same animal that he was nearly two centuries back. With the exception of the Wellesley Arabian, said to have been bred in Persia (but the assertion is unaccompanied by proof), which measured 15 hands 2 inches high, all the rest that have been imported have been little better than Galloways, which must be attributed to two causes—first, the want of being forced, as our own horses are, in their colthood, by high keep; and, secondly, by adhering too closely to the indigenous breed, or that whose blood is unmixed, by which means it has dwindled. Accurate observers must have noticed that the greater part of the horses brought to this country as Barbs and Arabians have exhibited a palpable deficiency in the points contributing to strength, and the want of general substance is apparent at first sight. It is true that, of late years, their estimation has so diminished in this country that no great pains have been taken to procure stallions of the highest caste, and scarcely any mares have been imported, and several of those sent over have been accompanied by very unsatisfactory pedigrees. We are, however, inclined to think that, as the immediate descendants of such horses are found quite inefficient as race-horses, and but few of the second or third generation have turned up trumps, unless as a rational experiment, the breeding of *race-horses* from Arabians is at an end.

We have reason to believe, that the best use to be made of Eastern horses, would be for the production of the English hunter, by the best-shaped hunting mares, nearly thorough-bred. By the help of the dam, and our present improved system of keeping young horse-stock, there would be little fear of the produce not coming to a good size, even in the first generation, as it is, for the most part, the property of these horses to beget stock larger than themselves; but by crossing the female produce in the second with our large thorough-bred horses, hunters for heavy weights might be looked for, with every prospect of success. We know that the virtue of the blood, or constituent parts, of the horse that was no racer (Marske, the sire of Eclipse, for example), has produced a racing son, by acquiring proper formation of parts from the dam; and if to the fine form of the English hunter, could be added the firmness of leg and sinew for which the Eastern horse is so conspicuous, but in which the English hunter is too often deficient, in conjunction with the larger muscles, more highly condensed bone, and well-known powers of endurance of the Eastern horse, not omitting his action, which is generally first-rate, but of which a proper judgment could be formed previously to the choice of the stallion, a great improvement upon our present race of hunters would be effected; and all such as were known to be thus bred, would meet a ready sale. It is a well known fact, that some of the most brilliant hunters England ever produced, were got by Arabian stallions; and one, by Lord Clive's Arabian, was decidedly the best horse in Leicestershire, in Mr Meynell's day, over every description of country. He was the property of the late Mr Childe, of Kinlet Hall, Shropshire, who is said to have been the first to introduce the present very spirited style of riding after hounds. Of late years, there have been some very good hunters of this breed in the royal hunt. A powerful Toorkoman stallion would not, we think, fail in getting hunters out of good English mares. That breed is the largest of any of the Eastern horses, owing to being reared on better land.

One word more on the subject of the Eastern horse, as connected with the English turf. Owing to the doubts and uncertainties that hang over the pedigrees and countries of the most celebrated stallions and mares which laid the foundation of our present breed of racers, it is impossible to determine to which individual breed, whether to the Turkish, the Barb, the Arabian, or the Persian, are the greater advantages derived from them to be attributed. They appear to us to be pretty equally divided. To the Byerly Turk we are indebted for the Herod blood (sire of Highflyer); to the Godolphin Arabian, said to be a Barb, for the Matchem blood, the stoutest of any; to the Darley Arabian (the sire of Flying Childers), for the Eclipse blood; and to the Wellesley Arabian, believed to be a Persian horse, to the only real advantage gained to English race-horses, by a foreign cross, in later years. It must, however, be observed, that the most famous horses of the last century, such as Childers, Old Crab, Eclipse, and King Herod, did not appear on the turf before they were five years old; which leads us to suppose that the failure of horses subsequently bred, as they themselves were bred, from Oriental blood, and trained at an early age, may, in great part, be attributed to the fact of the immediate produce of such horses requiring more time to come to maturity, or even to a certain degree of maturity, than those, like our present breed of race-horses, further removed from such blood; and the cause may be attributed to climate. It is reasonable to suppose that the produce of stallions and mares bred in the torrid zone, would come slower to perfection in a damper and colder country than it would have done in its own; and we may infer from this, that in proportion as horses were brought earlier to the post, and races shortened in distance, Eastern blood got into disrepute.

In Great Britain, from the highly cultivated knowledge of the mechanical structure of living bodies, with the junction of best shapes, although but for racing, this knowledge would have been comparatively in its infancy, the horse has arrived at the highest state of perfection of which his nature is capable; and in whatever country and in whatever climate his racing powers are put to the test, he has scarcely found a rival, excepting under very disadvantageous circumstances. It is true his *lasting* qualities were doubted, and he was challenged to rebut the charge; and the following was the result. On the 4th of August 1825, two second-rate English racers, Sharper and Mina, contended against the most celebrated Cossack horses from the Don, the Black Sea, and the Ural, in a race of the cruel length of 47 miles. At starting, Sharper and Mina ran away with their riders more than a mile, and up a steep hill, when the latter horse broke down, and pulled up. Half the distance was run in an hour and forty minutes. In the last half, only one of the Cossack horses was able to contend with Sharper, who, notwithstanding every foul advantage was taken by changing the weight, and dragging along his opponent by a rope, won his race in gallant style, performing the distance in two hours and forty-eight minutes. At starting, the English horses carried three stone more weight than the Cossacks; and, during the latter half of the race, the one Cossack who remained in it was ridden by a mere child. Every trial over the desert, no matter what the distance, during 1826-55, between English and Eastern horses, has been attended with precisely the same results.

From the great export trade to the Continent of English horses, and particularly those of full blood, occupiers of land cannot turn their attention to a much surer source of profit than that of breeding horses, provided they go judiciously to work. But, unfortunately for the speculators in this branch of rural economics, too much is left to chance and experiment, and thus horse-breeding becomes absolutely a matter of speculation, instead of a matter of judgment. It is true, those noblemen and gentlemen whose studs have become eminent on the turf cannot be included in this charge, unless they are extremely prejudiced in favour of a particular sire; but even with the benefit of great experience, and various other advantages, the utmost exercise of their judgment is required to ensure even a prospect of success against such a field as they have to contend with. Having said this, we will lay down a few practical rules for breeding and rearing the various kinds of horses now used in Great Britain, commencing, as before stated, with that of the race-horse.

In the first place, it may be observed there has been a great deal of discussion in various publications on sporting, but to very little purpose, on the much agitated question, "What constitutes full blood, or what is termed a thorough-bred horse?" We consider this question as very easily decided; the term "thorough-bred horse" merely implying one that can be traced through the stud-book, by sire and dam, to any Eastern stallion, or to what were called the royal mares, imported by Charles II., as they, together with two or three of the first imported stallions, form the *ne plus ultra* of all racing pedigrees. As to the assertion, that for a horse to claim the title of thorough-bred it is necessary he should be of pure Oriental descent, it cannot for a moment be supported; as, independently of the fact, that only two mares are stated in the *Stud-Book*, or elsewhere, on authority, to have been imported into England in the early days of racing, it is well known that the first British race-horses were those of British breed, changed, ameliorated, and at last perfected by the admixture of Eastern blood, and judicious crossing afterwards.

The effect of what is called crossing blood is as follows: The first cross gives one-half, or 50 per cent.; the second 75 per cent.; the third $87\frac{1}{2}$ per cent.; and the fourth $93\frac{3}{4}$ per cent. In sheep, after this, if the ewes have been properly selected, the difference in the wool between the original stock and the mixed breed is scarcely perceptible; but with the horse, the breeder must not stop here, if he means to produce a race-horse; and a curious fact is stated respecting sheep, on the authority of the Count Veltheim, of Brunswick, an extensive breeder of that species of stock. "It has frequently occurred to me," says he, "that rams, which, after an improvement of four or five descents, have rivalled all the *visible* qualities of the purest Merinos, when employed in propagation, have got very ordinary lambs, and consequently they are not fit to be used for breeding. On the other hand, a fact may be stated, wherein after a very opposite cross, pure blood, with evident improvement upon the original stock, was procured on the eighth descent. The late Lord Oxford, very celebrated for his greyhounds, finding them degenerating in courage, crossed his best bitches, with a bull-dog. The result was, after several re-crossings with pure blood, that breed of greyhounds for which he was so eminently distinguished. The immediate descendants, however, of the Eastern horses, have, almost without an exception, proved so deficient of late years, that our breeders will no more have recourse to them than the farmer would to the natural oat, which is little better than a weed, to produce a sample that should rival that of his neighbours in the market."

Much speculation has also been indulged in as to the effect of close affinity in breeding the race-horse, or what is called breeding in-and-in; a system which has eminently succeeded in breeding cattle, and also with the late Lord Egremont's racing stud. Beginning with Flying Childers, several of our very best racers have been very closely bred;

and it certainly appears reasonable that, as like is said to produce like, if we have high form and superior organization in an own brother and sister, that high form and superior organization would be very likely to be continued to their incestuous produce. In a work called *Observations on Breeding for the Turf*, published several years back by Nicholas Hankey Smith, who resided a long time among the Arabs, the author gives his opinion that colts bred in-and-in show more blood in their heads, are of better form, and fit to start with fewer sweats than others; but when the breed is continued incestuous for three or four crosses, the animal, he thinks, degenerates. By breeding in-and-in, however, he does not insist upon the necessity of breeding from brother and sister, or putting a mare to her own sire, or the sire to her own dam; but after the first cross, to return to original blood. A proof of the good effect of a close affinity in race-horses may be found in the produce of the dam of George IV.'s favourite mare Maria. By those celebrated stallions, Rubens and Soothsayer, they were worthless; but by Waterloo and Rainbow, grandsons of Sir Peter, and thus combining much of her own blood, they could run to win.

The first and most important point in the choice of a blood-mare for a racing stud, is the soundness of her constitution and limbs; although, of course, it is desirable she should be of good size and shape, with substance. How highly soever she may be bred, and however well she may have run, if she have not a sound frame, she cannot be depended upon to breed racers. If she have never been trained, of course the risk is increased; but, in either case, her form and action must not be overlooked, as it too often is, rendering the breeding of thorough-bred stock a mere matter of chance. Should she have appeared in public, her racing capabilities are to be consulted. For example, if pace (speed) was her best, as the jockies say, a stallion should be selected, who, by the known stoutness of his running is likely to tie her produce to pace, or, in other words, to give them both speed and endurance in a race. Her frame should be roomy, or her produce will be apt to be small, although, it must be admitted, there are exceptions to this rule. She should be of what is termed fashionable blood, for, if she be not, and her produce should come to the hammer, *previous to trial*, they would prove utterly worthless in the market.

It cannot admit of a doubt, that it is trespassing on the powers of nature to expect a mare, or any other female animal, to nourish her fœtus, in embryo, so perfectly during the time she is giving suck, as if she were dry or without milk. Nevertheless, it is customary to put all blood-mares to the horse the ninth day after foaling, and it is almost too much to expect that the owners will let them lie fallow, although they may in some measure resemble the man who cut up his goose to get at the golden egg. During the period of gestation, however, the thorough-bred mare should be highly kept. All animals well fed, produce their species of a superior description to those which are not well fed; and nothing more forcibly shows the beneficial effect of warmth in rearing superior varieties of the horse, than that the half-starved horse of the desert should be as good as he is even now found to be.

In a racing-stud, the period of putting mares to the horse is much earlier in the year than that of any other sort, by reason of their produce being almost always called upon to go into work before they are two years old. In fact, they can scarcely be dropped too soon in the commencement of a new year, where proper accommodations are provided for them. A peep into the seven volumes of the *Stud-Book* will satisfy inquirers into these matters, that some mares have produced more than twenty colts and fillies, and, in a few instances, a third of them have proved good runners; but, we should be inclined to think that the average would not exceed six, as the produce of each mare. It sometimes occurs that mares are put into a breeding-stud, when affected by severe lameness in the feet. When this is the case, the operations of neurotomy or unnerving is recommended; as pain, by producing fevers, not only is injurious to the formation of the fœtus, but often causes abortion. Bad, putrid smells, or being struck on the nose, also produce abortion in brood mares.

Virgil, in his excellent remarks on breeding horses, tells those of his readers who wished to gain a prize, to look to the dam; and, until of very late years, it was the prevailing opinion of Englishmen, that, in breeding a racer, the mare is more essential than the horse to the production of him, in his highest form, and we know it to have been the notion entertained by the late Earl of Grosvenor, the most extensive, though not perhaps the most successful, breeder of thorough-bred stock England ever saw. The truth of this supposition, however, has not been confirmed by the experience of the last half century, and much more dependence is now placed on the stallion than on the mare. The racing calendar, indeed, clearly proves the fact. Notwithstanding the prodigious number of very highly bred and equally good mares that are every year put to the horse, it is from such as are put to our best stallions that the great winners are generally produced. This can in no other way be accounted for, than by such horses having the faculty of imparting to their progeny the peculiar external and internal formation absolutely essential to the first-rate race-horse; or, if the term "blood" be insisted upon, that certain innate but not preternatural virtue, peculiarly belonging to some horses but not to others, which, when it meets with no opposition from the mare, or, in the language of the stable, when "the cross nicks" by the mare admitting of a junction of good shapes, seldom fails in producing a race-horse, in his very best form. The blood of some mares will only cross successfully with one particular horse, and Phryne has, for instance, not been very successful since Pantaloon died. Emma, Arcot Lass, and Barbelle have each produced a brace of Epsom or St Leger winners to a different horse. Mandane has also a strong claim to rank with the world-famed Prunella, and she foaled Altisidora by Dick Andrews, Lottery by Tramp, and Brutandorf by Blacklock. It is obvious, then, that owners of racing studs should not hesitate at paying the difference between the price of a first-rate stallion and an inferior one; and there is always one of the former to be found, to suit every description of mare. Breeders of all kinds of horses, but of the race-horse above all others, scarcely require to be cautioned against breeding from mares, or putting them to stallions, constitutionally infirm. By "constitutionally infirm," is chiefly implied having a tendency to fail in their legs and feet, during their training, which too many of our present racing-breed are given to. Still there are as many good judges who side with the earl, and affirm that the exterior conformation of the foal is principally derived from the sire, and its interior from the dam; thus throwing the responsibility of its sound or unsound lungs, which are, after all, the great test of a good racer, on the latter.

In consideration of the preference given to the stallion over the mare in the propagation of racing-stock, may be quoted the following passage, from part 3d of Percival's *Lectures on the Veterinary Art*, London, 1826:—"It might be supposed that the part the male takes in fecundation is comparatively a very unimportant one; it must be remembered, however, that the copulative act is the essential first cause, that therein the action of the organs is natural and sympathetic, and that the result is the generation of a new animal, bearing a likeness to one or both of the parents; from which it would appear, although the physical part of the male is simply to project the sperm into the female, who alone has the power of rendering it efficacious,

Race-Horse.

that the influence of the sperm is much greater in the generative process than we seem to have any notion of, or at least than we have been able to reveal the nature of in physiology."

Rearing of Young Racing Stock.

Under all circumstances, there is too much resemblance between the speculations of the turf and a lottery; but, as the prizes it exhibits are valuable, the most effectual means of obtaining them should be adopted. It signifies little what care and circumspection have been exercised in the selection of stallions and mares, with a view of breeding racers; the prospect of success is very limited indeed at the present day, unless the produce be reared according to the improved system acted upon in our first-rate racing establishments. Such was the pertinacity of opinion combined with long-established prejudices, and in direct opposition to the daily acknowledged fact, of dry and warm countries having been the first to produce the horse in perfection, that it is only within a very few years that young thorough-bred stock has been reared in the manner in which it should be reared. A thorough-bred colt may now be said to be in training from the day on which he is dropped, so great is the care taken to force him into shape and substance. Not only is he drawing from the teats of his dam the milk of a highly fed animal, and consequently, in itself highly nutritious, but, before he is twelve months old, he eats nearly two bushels of oats per week. The time for expansion of frame is youth, and, when we see a two-year-old at the post, with eight stone seven pounds on his back, looking like a horse able to carry a light man after hounds, we most cordially assent to the answer given by the most experienced Newmarket trainer of the present age to the question, What is the best method of rearing a racing colt? "First observe," said he, "that the blood, or cross, is good; secondly, breed him as you would a sheep, from a roomy dam; and thirdly, give him as little green meat as possible, and as much corn as he will eat." The trainer we allude to has now retired, but he had all the young stock of the Duke of Grafton, and many of the first and most successful sportsmen in England, through his hands, and the annual disbursements of his establishment exceeded ten thousand pounds. That dry and hard food, as it is called, is the natural food of the parent stock from which our race-horses are descended, is beyond all doubt; and that the firmness of their acting parts is attributable to that, and to the warmth and dryness of the climate, is also admitted. Is it, then, to be wondered at, that breeders of horses, and not only of race-horses, have at length found out that dry food and warmth have the same effect in the Temperate as they have had, and now have, in the Torrid Zone? that they have discovered that, when colts are bred on rich succulent food, and subject to a humid atmosphere, the bulk of the body increases out of proportion to the strength of the bones; and to these predisposing causes are to be attributed most of the false points which we find in horses, such as fleshy shoulders, deficiency of muscle, weak pasterns, and flat feet? Virgil discovered this nearly two thousand years ago, and, when speaking in praise of Epirus, as suitable to the breeding of horses, emphatically observes:

> "Continuo has leges, æternaque fœdera *certis*
> *Imposuit natura locis.*" *Georg.* i. 60.

So careful, however, now are some of our principal and most successful breeders of race-horses to avoid these evils, that not only is a thorough-bred colt eating grass *ad libitum* become a rare sight, but he is not suffered to be exposed to rain, even in the midst of summer, no, not even to a temporary shower. The effect of rain upon horses' backs, is found to produce the worst of diseases—glanders, for instance—as is well known to all cavalry officers who have been on service with their regiments; and it cannot be innocuous to the highly-bred foal or colt. That he should be sheltered from the cold of winter, need scarcely be insisted upon here, although we are rather inclined to think that, in the generality of breeding establishments, he is more exposed to weather in the winter than he ought to be. There is no objection to a *moderate* allowance of carrots, and a little green food; but according to the old Greek proverb, Ἄλλος βίος, ἄλλα δίαιτα, *another life, anther diet*, we must hear no more of the "natural food" of an animal insisted upon by many, who is so far called upon to outstrip the laws of nature as to begin to work at fourteen months old, and to appear at the starting-post at two years old, displaying the form, character, and strength of one nearly arrived at maturity. Neither is the land on which a racing-stud is situated oftentimes sufficiently considered; but a want of such consideration has been the source of great loss. It is in vain to expect success unless upon that which is dry, and consequently of sound subsoil; and what is termed "upland ground" is most favourable. Walls, independently of security, are preferable to hedges for inclosures to breeding paddocks, as the latter harbour flies, which are very injurious to young stock, and also to their dams, in hot weather; but the present small dimensions of breeding paddocks, not exceeding a quarter of an acre, and many still less, preclude the use of hedges.

Racing colts are physicked when foals, and periodically afterwards; their hoofs, also, are pared with a drawing-knife, that, by shortening the toe, the heel may have liberty to expand. Physic, in this case, may be termed the safety-valve, and such it is in reality, for this system of forcing nature cannot be free from danger. It is found, however, materially to promote growth, as indeed does the work that our racing-colts perform at such a very early age. Muscular action produces muscular strength, and growth will be the result; and we have seen colts sixteen months old measuring 15 hands 2 inches.

Racing colts can scarcely be handled too soon:—

> "Dum faciles animi juvenum, dum mobilis ætas,"

as Virgil says of the bulls; and Horace illustrates the necessity of early erudition of the human species by the excellence of horses which have been well broken in when young. The first breaking in of colts is also alluded to by Ovid, who, like Horace, is in favour of very *careful* treatment of them, and reminds us of the necessity of it in the following beautiful line:—

> "Frænaque vix patitur de grege captus equus."

The system of breaking colts, however, is not only thoroughly well understood in our racing establishments, but is accomplished with much less severity than it formerly was, and consequently with less danger to the animal.

The time of foaling is one of great interest to owners of valuable brood mares, and particularly so when the produce is engaged, perhaps heavily, or when they are of what is termed a running family. The attention of the stud-groom is directed by sundry forewarnings, the most palpable of which is what is called "waxing of the udder," and appearance of milk, which generally precede parturition two or three days, but in some instances more. As the mare brings forth on her legs, there is little fear of the foal being overlaid by the mother; but the less she is disturbed the better, lest she should trample on its legs. Her treatment afterwards is now so well understood, that nothing requires to be said about it; but a bran mash, with from four to six ounces of nitre dissolved in it, given as soon as she has brought forth, keeps off fever. The great preventative of accidents to foals, is the simple contrivance of rollers on the sides of the door-frames, which secure them from being injured as they rush out of the hovel or shed by the side of their dams, especially in cases of alarm.

Race-Horse.

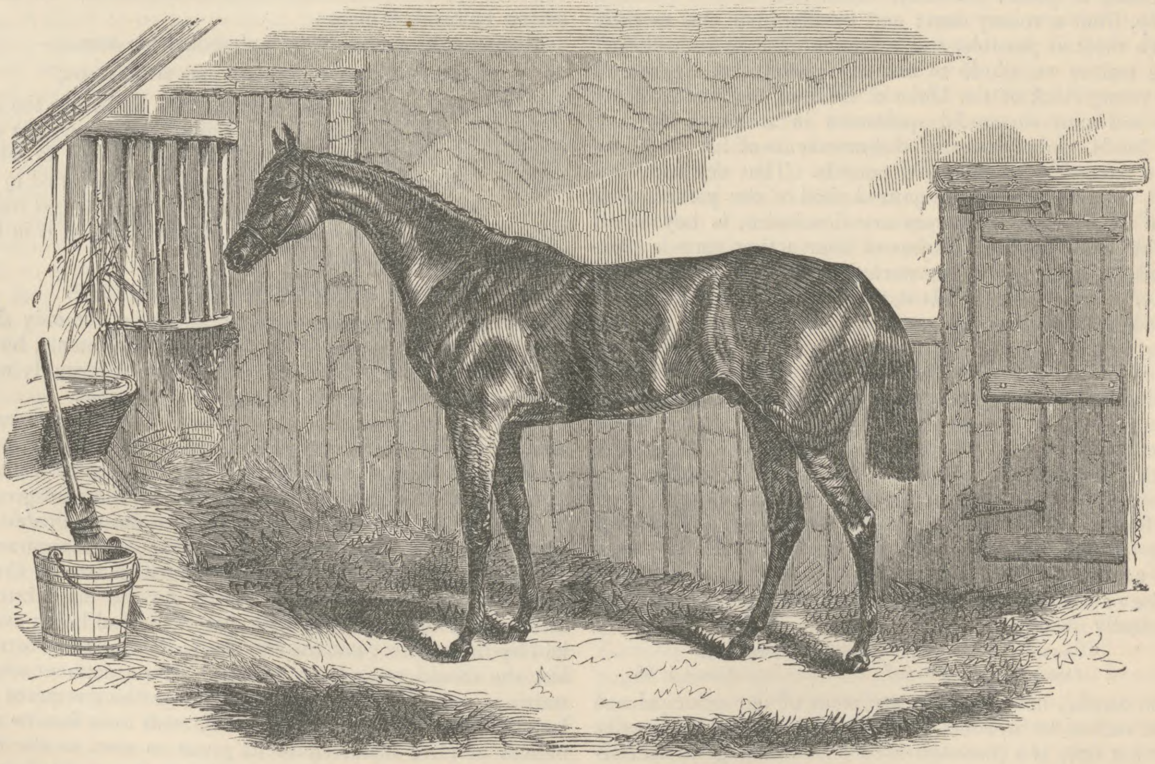
Some persons prefer purchasing to breeding young racing stock, and it is difficult to determine between the advantages and disadvantages of the systems. It is true that, in the first case, the purchaser has a certainty of some return for his money, inasmuch as he gets his colt or filly, which the breeder may never get, after incurring a great expense on the mare. The price of a promising yearling, from a hundred to a thousand guineas, is a large sum to begin with; and we cannot, in this instance, say with Varro, that "a good horse is known from the first." If purchased after he has won in public, at two years old, he is often not to be purchased, if he has good engagements, under one to three thousand guineas, a large sum to realize, when added to concomitant expenses. Nothing but the immense amount of stakes for young racing-stock can justify such a speculation. For example, in 1824, a filly of the Duke of Grafton's won four thousand four hundred and fifty guineas, public money, by only starting twice; and Crucifix cleared L.4805 during her two-year-old season in 1839.

One of the principal drawbacks from the prospects of success in a racing establishment, is a complaint called the *distemper*, a sort of catarrhal fever, the cause of which is generally attributed to atmospheric influence, and also to any other which may produce what is termed a cold. Unlike common catarrhs, however, the distemper will run through a whole stud of horses; and if it do not, as it frequently does, end in an affection of the lungs, it leaves a lassitude behind it, which requires some time to remove. As a hot sun, with cold winds in spring, and the humid air of the autumn, are the chief predisposing causes of this complaint, an even temperature in the stable, and warm clothing when out of it, together with avoiding exposure to extremes of heat and cold, are the best safeguards against its attacks. It may be compared to a frost over the blossoms, which in one night blasts all former hopes of a crop.

Race-Horse.

A most interesting event to a breeder of thorough-bred stock is the trial of their racing powers, which at once decides the question of their being worth the expense of training to run or not. There is a great deal of judgment necessary in the act of trying even old horses, but still more is required to form a just estimate of young ones, from the difficulty of knowing when they are quite up to the mark, as well as of keeping them there. They are generally tried early in their two-year-old season, or very late in their yearling one. It is also not one jockey in thirty who can "try" well; and, as a general rule, he ought to ride the trial horse, not the one whose powers are to be tested. William Scott was a first-rate "taster," as it is termed, and so was Frank Butler.

But we have not yet spoken of the form of the race-horse, which we will now describe; and as nothing can be considered characteristic of a species, but what is perfect of its sort, we will so far endeavour to make the pen perform the task of the pencil, as to portray his cardinal points, as nearly perfect as such means will admit of. Nature herself, perhaps, rarely exhibits perfect models in the animal world, leaving the completion of her skill to human sagacity; neither is undeviating symmetry absolutely necessary in a race-horse. In every composite, however, beauty consists in the apt connexion of its parts with each other; and just proportions in the limbs and moving levers, coupled with that elegance of form *in which there is no unnecessary weight to oppress the muscles*, so peculiar to the highly bred race-horse, is all that need be insisted upon in a racer. It is nevertheless hard to say what horse will make a racer; and also what will not, until put to the test; for, how many horses have appeared, which the eye of the sportsman would not wish to study, and yet have proved themselves very capital runners? This excellence, however, in those "cross-made horses," as they are termed, not misshapen ones, arises, as has been before observed, from their possessing parts conducive to speed and action, not, perhaps, very strikingly displayed, but, by means of greater length and depth, and a peculiar manner of setting on of the acting parts, enabling them to excel others, much handsomer to the eye, but wanting in either proper declivity, length, or, what is still more probable, in circular extent of those parts. Thus, as the wise man, according to the Stoics, alone is beautiful, so is a race-horse to be admired solely for those points which make him a good race-horse.



Race-Horse.

Although symmetry and proportion form a perfect figure, and they become deformities when any of the component parts exceed or fall short of their due proportions, yet it is not always necessary to measure by the standard of perfection. Suffice it, then, to state the generally approved points of the English race-horse.

We commence with the head, not merely because it has always been considered as the most honourable member in the human frame, but as it is one of the leading characteristics of the thorough-bred horse. His broad, angular forehead, gives him that beautiful expression of countenance which no other breed possesses; and the tapering of the face from the forehead to the muzzle, forms a striking contrast with the large face of the cart-horse, and the forehead scarcely wider than the face. The race-horse should have a black, lively, and rather prominent eye, which denotes a sound constitution; and as horses do not breathe through the mouth, but only through the nose, the nostrils should be rather expanded and flexible, that they may accommodate themselves to quickened respiration, as the speed of the animal increases. But they should not be over large. "Naribus *non angustis*," says Varro, and he is right. Beauty in the head of the race-horse, however, is only a secondary consideration to the manner in which it should form a junction with the neck, as on that, in a great measure, depends the goodness of his wind in a race. His jaws should not only be thin, and not approach too near together at the throat, but they should not extend too high towards the onset, or they will impede his freedom of breathing. The neck of all horses should be muscular; but what is called a loose neck in a race-horse, is not so objectionable as in a hunter, and is considered as indicative of speed. But as the head of a horse may be called the helm which guides his course, changes, and directs his motions, it is not only desirable that, as he cannot move his head but with the muscles of his neck, those muscles should be pliant, but that he should also have what is termed a good mouth. It is asserted that the weight of the head and neck, the effect increasing with their distance from the trunk, adds to the speed of the horse, by throwing his weight forward; but this is no argument for *additional* weight or length in those parts, which ought to be duly proportioned to the trunk. The neck of the race-horse should be in no extreme, but rather long than otherwise, and not too much arched.

As horses are said to go with their shoulders, these may be considered as highly important points. They vary in form more than any other part of the horse's frame. Those of Flying Childers rose very high and fine towards the withers; whereas, a firkin of butter rested, unsupported, on the withers of Eclipse, when in covering condition. Upright shoulders, however, being (though not in Teddington's case) an impediment to speed, obliquity of the scapula is absolutely necessary, but we do not insist upon their running fine at the withers. We consider the shoulders of Eclipse to have resembled those of the greyhound, wide at the upper part, and nearly on a line with the back. Large, or even what are called coarse shoulders, contribute greatly to strength, and are no impediment to speed, if there is proper declivity of the scapula, or shoulder-bone. The withers, when high, or thin, should enlarge gradually downwards, and there should be four or five inches between the fore-thighs, but less between the feet.

The true position of the limbs is a most material point in the race-horse, as it causes him to stand over more ground than one which is otherwise formed, although possessing a more extended frame. One of these essential points is, the setting on of, and length in, the fore-arm, or part from shoulder to knee in the fore leg; and another is, the declension of the haunch to the hock in the hind leg, which is termed "well let down in the thigh." It is from having those points in excess, that enables *the hare* to describe a far greater circle, and cover more ground at one stroke, than any other animal nearly double her size. In fact, the arm should be set on at the extreme point of the shoulder, which insures this act of extension, and also adds to the declivity of the shoulder. The knee should be broad and flat, and if appearing somewhat prominent, the better. All the Herod legs had prominent knees (and no legs stood work better than they did), concussion in galloping being diminished in legs so formed. The cannon, or shank, from knee to fetlock, should be of moderate length in the race-horse (longer than in the hunter), and, above all, the leg should appear flat, not round, with sinews and bones distinct; and the former appearing to be very firmly braced. The pastern of the race-horse should be long, lax, and rather small than otherwise; length and laxness serving as springs, and smallness contributing to agility, and consequently to perseverance or bottom. Some comparison will hold good between this point in a horse, and the "small of the leg," as it is called, of a man, in contradistinction to the calf. Under the pressure of fatigue, no man complains of the "*small* of his leg" giving him uneasiness, but his calves often give him notice that he has done too much. The hoof of the race-horse should be of moderate size in proportion with the leg above, but, of course, those whose hoofs are unduly small cannot get well through dirt.

Race-Horse.

We have already alluded to the bone of the thorough-bred horse, which much exceeds that of any other variety of this animal, in its compactness and solidity; which qualities, as the span in the gallop must give a shock in proportion to its length, are admirably adapted to the race-horse. We cannot say of him, what Job said of the behemoth, that "his bones are like bars of iron;" yet, as in proportion to the muscular power of the animal is the dense quality of the bone, that of the race-horse need not, nor should not, be large. Experience teaches us, that bones very rarely break; fractures, when they do occur in racing, being almost invariably in the joints; and rather small bone in the leg of a race-horse, supported by broad and well-braced sinews and tendons, placed distinct from the bone, and forming what is called a flat and wiry leg, is most desirable, and found to be indicative not only of speed and endurance, but likewise of soundness in severe work. It is only those who are ignorant of the anatomical structure of animals, that fix the basis of strength in the bony substances alone, not considering the muscular appendages, which constitute the main-spring of strength and action.

As the strongest bodies owe their vigour to the milk they receive in their infancy, our recommendation to keep brood mares well will not be considered as unsuitable; but the connexion between milk and bone is also deserving of a remark. When animal bones are divested of their oil and jelly, the earth which remains is chiefly lime, united with phosphoric acid. It is worthy of notice, that phosphate of lime is found in abundance in milk. This seems to indicate, that Nature thought fit to place, in the first nourishment of animals, a quantity of osseous matter, with a view to the necessary celerity of the formation and growth of the bones in the earliest stage of their lives. This is one of the numerous instances of the beneficence of the Creator, exemplified by the science of chemistry, and shows the advantages to be expected from a good flow of milk in a mare that is well fed; and it is a remarkable fact, that the nearer the female approaches to the period of parturition, the more is the milk charged with this calcareous phosphate. Nor is it until the digestive organs of the food are sufficiently strengthened to answer the purposes and work of animalization, that this earthy salt disappears.

But to proceed with the form of a race-horse. The race-horse should have length, but the length should be in his shoulders and in the *quarters;* that is, the part posterior to the hips, and not in his back. To give him that elegance of form for which he is so conspicuous, there should be no acute angle or any straight line. His shoulders should go into his neck at the points, *unperceived*, and his back should sink *a little* behind the withers, which gives his rider a good seat, and does not in the least diminish his strength. On the contrary, horses with very straight backs are generally deficient in their fore-quarters, as well as in their action; and we have known some very good racers, Glencoe and Haphazard for instance, considerably hollow-backed. There should be a little rise in the loins, just behind the saddle; but the race-horse cannot be too closely ribbed up, if you wish him to stay a distance, and carry weight. The ribs should stand out from the spine, producing what is called a round barrel, together with depth of carcass, a formation which not only gives strength of body and constitution, but, by admitting the intestines to be comfortably lodged within the ribs, imparts freedom of breathing, activity and beauty to the whole frame of the horse, other parts being proportional. These useful points must not be carried to an extreme, or the horse may be "too heavy for his legs;" and we know that light-bodied horses save their legs much in their gallops, which accounts for mares and geldings standing the severity of training to a later period of life than stallions, by reason of the former requiring less work, from not generally carrying so much flesh as the latter.

There is no part, excepting the head, so truly characteristic of high breeding in the horse, as his haunch. If a little of the elegance of the parts, however, is diminished by the width of the hips, it will be recompensed by increased strength in the animal, as is the case with broad-shouldered men; and when accompanied with good loins, these protuberances of the ilium can scarcely be too great for the purposes of power and action. We next come to the thigh, the form and substance of which is most material to the race-horse; for although horses are said to go with their shoulders, the power to give the impetus in progressive motion comes from behind. With all animals endowed with, and requiring extreme rapidity of motion, the thigh is furnished with extraordinary powers and length—the hare, for example, whose thighs are let down to a great extent for their size, and the lower part of the hinder leg placed under them, as that of the racer should be, from a proper curve of the hock. The speed of the ostrich arises from the power of the muscles from the pelvis to the foot; and the thigh of the fighting cock is a point much considered by breeders. It is not necessary that a race-horse's thigh should be very large, but it should exhibit well developed muscle. Descending lower in the limb, we arrive at the hock, a very complicated joint, but the form of which is most important in the race-horse. It should be large and lean, and the point of it projecting behind the body, which greatly increases the power of the lever in action, as will presently be most satisfactorily shown.

Size.

The point of perfection in most things lies at a middle distance between two extremes, and such is the case here. The medium height, about 15 hands 2 inches, to 15 hands 3 inches—4 inches to a hand—is the best for a race-horse. As the long beam breaks by its own weight, so large animals have rarely strength in proportion to their size. On the English turf, however, the very large horses that have appeared have, with a very few exceptions, not been found so good under high weights, as those of a medium height; and several instances are on record (Meteora, Whalebone, and others, for example), of the best horse of his year being very nearly the lowest. Ancaster Starling, Gimcrack, Highlander, Milksop, and several of the best 14 hand 2 inch horses of the last century, could also defeat 16 hand horses cleverly at 4 miles, under 12 stone; and those modern dwarfs Mickey Free and Midas have carried 8 st. 7 lbs. with good success.

The following are amongst the principal and essential points of a race-horse, pointed out by Mr Darvill in his *Treatise on the English Race-horse*, London, 1834:—

"His head should be small and lean; his ears small and picked; his eyes brilliantly large; his forehead broad and flat. . . . . . His throat should be clean, and fine from the butt of the ear down to its centre, with a good wide space between the jaw-bones, which latter should be thin. . . . . The neck should be moderate in length. I prefer its being wide; I mean its width should be formed by the substance of muscles which pass along each side of the top part of it; from the withers to the head it may gradually rise a little in its centre, but by no means to any extreme, as I have a great aversion to a high-crested race-horse. Indeed, I would prefer that his neck should be rather of the ewe or deer-like shape, than that it should be loaded on the top. As to the lower part of the neck, I have no very particular remarks to make, further than the trachea or windpipe should be spacious and loosely attached to the neck on its way to the lungs.

"The withers may be moderately high, and, if the reader like, they may also be moderately thin; but, with respect to this latter point, I am not so very particular, provided the shoulders lay well back. From the withers the back commences. I confess that appearance may be in favour of a horse that has his back a little low or hollow. As a saddle-horse this may be all very well, but for a race-horse to have strength and liberty of stride his back should be straight and moderately long, with the shoulders and loins running well in at each end. The loins should have great breadth and muscular substance, so much so as for them to have the appearance of being raised as it were on their surface; and those muscles posterior to the loins should fill up level the top part of the quarters to the setting on of the tail, which latter should be set on pretty high up."

After describing the fundament, which, if small, close, and tight, and rather projecting than otherwise, Mr Darvill considers as a good constitutional point, he thus proceeds:—"I now come to speak of the body, or what is by some people commonly called the 'middle piece' of the horse, and which is divided, internally, into two cavities by a muscular substance called the 'diaphragm.' The anterior cavity, the chest, contains the lungs, the heart, &c. The posterior one, the abdomen, contains the stomach, intestines, liver, kidneys, &c. Now, with respect to the external form of the body, which contains and protects all those numerous organs so important to life, I shall first make my observations on the chest. To use a common phrase, and somewhat an expressive one, a horse in this part should be what is called 'well over the heart,' that is, he should be deep in his girth, round or well arched in his ribs. I mean by this, that a rider on the back of a race-horse (as they are generally better about the chest than horses in common use), should feel he has some breadth or substance between his legs; and there should be a good swell of muscle before his knees, or the centre of the flaps of the saddle. The chest, thus spaciously formed, gives room for respiration, so that in training the horse's wind can be brought to the greatest perfection, which enables him to run on in long lengths. The next part to be treated of is the abdomen or belly, or what is usually called the carcass. It may perhaps appear a little strange, but I have a great aversion to what is commonly called a good-carcassed horse, nor am I particularly partial to a large sheathed one. I like both these parts to be in the medium, as I do also that of his being well ribbed up. It is true that a horse being well ribbed up denotes strength, and a short close-made race-horse is, in running, handy at his turns, and, as I have already noticed, he is generally a pretty good one under high weights

Race-Horse.

over a small round cock-pit course; but this description of course and sort of running is not now so much practised as formerly, or rather it is a sort of racing that does not exactly suit long-striding horses, as most of those are that run in Newmarket. Another thing is, that horses with large carcasses are mostly great gluttons; they put up flesh very rapidly, and are very difficult and troublesome to train, in consequence of their constitutions being too strong, or proportionably too much for their feet and legs. Such horses not only seldom remain long in training, but they cannot remain long in condition without their becoming stale in themselves, as also on their legs, and those are my reasons for objecting to very large-carcassed horses; yet I do not wish horses to be what is termed 'tucked up' or waspish in their carcasses. I like a horse's carcass to be in the medium; that is, it should be straight and handsome from behind the girths of his saddle; and what will make up sufficiently well, and give him sufficient strength of constitution, is the well formation of the parts already noticed, as the chest, the loins, and the fundament.

"To return to the fore extremities. The shoulders commence from a little below the withers; they should lie most particularly well back, should be deep, broad, and muscularly strong; yet those muscular parts should appear to the eye as being moderately so, that is, not unproportionally loaded. These muscles should be distinctly seen, there should be no appearance of fat, or, as it is technically termed, 'adipose membrane.' The shoulders cannot well be too oblique in their descent to the front of the chest; here, on each side, a joint is formed by the lower part of the scapula or shoulder-blade being united with the upper part of the humerus or arm-bone. Those joints, thus formed, are usually called the points of the shoulders, which points should appear straight or level. There should be no coarse, projecting, or heavy appearance about the points of the shoulders of such horses as are intended to race; nor indeed does this often occur, unless where it happens that the chest or counter of the horse is unproportionally wide. In taking a front view of the chest, it should appear moderate as to breadth; and if its prominency is at all to the extreme, it should be in consequence of the fulness or substance of those muscles covering the breast, which muscles should be lengthy, and their divisions distinctly to be observed. The fore-arm should be broad and long, and most particularly well furnished with muscles on its top parts, inside as well as out; I mean by this, that the muscles on the top and inside of the arm should here be so large as to leave but a moderate space between the fore-legs, immediately under the chest, and which muscles should appear, as those in front of the chest, distinctly divided. The posterior part of the top of the arm is called the 'elbow,' this should appear (the horse in condition) somewhat on a level with the body; if it at all deviates from this appearance, I would prefer its standing in, to that of its standing unproportionally out. The knee-joint should be large, broad, and flat in front; generally speaking, the larger and broader all joints are in reason the better and stronger they are; and the longer, coarser, and rougher, their projecting points or *processes* are, the greater and more secure will be the lever for the muscles or tendons to act upon, provided such projecting parts or joints (as the hocks and pasterns) do not amount to disease, as that of producing spavins and ring bones. The legs from the knee to the fetlock cannot well be too short, neither can they well be too broad or too flat, nor their flexor tendon scarcely be too large or appearing too distinctly divided, as it were, from the leg. The fetlock-joint should also be large, and the pastern proportionally strong, but its length and obliquity should be in the medium. The wall or crust of the feet should also be moderately oblique, with the heels open, and frogs sound; this, indeed, is generally the state of racing-colts on first bearing their paddocks, if their feet have been paid proper attention to during the time they may have remained there. Yet the feet of such of them as have been some time in work will occasionally get out of order; they grow upright and strong; the horn gets hard and brittle, and the heels more or less contracted; almost all of which defects are too often occasioned from the want of proper attention being paid to them at the time of shoeing, and of proper applications being applied to them in the stables. Previous to concluding my remarks on the fore extremities, it may not be amiss to observe to the reader, that, supposing him to stand opposite to those parts of the horse, if the animal is formed in them, as I have already described, the centre of the top part of the fore-arm, to be well placed, ought to be nearly or quite in a parallel line with the top or fore-part of the horse's withers; and again, from the top part of the form-arm down to the foot, for the horse to stand firm and well, and have the power of using his fore-legs well, he should stand perfectly straight on them; I mean by this, they are not to appear too much under him, or too much out or away from him. Suppose again, for example, a man standing in front of the horse, and here taking a view of the foot, the centre part of the wall or crust should be in or on a parallel line with that lower part or joint of the shoulder, commonly termed its point. A horse's feet, thus placed, will neither be too much out nor too much in; but should his feet deviate from what I have here observed, by amounting to a fault, in turning too much out or too much in, I should prefer their being a little out, to that of the other extreme of turning in, and being what is called 'pigeon-toed.'

"I shall now proceed to describe the hind-quarters or posterior extremities. As may be supposed, the well formation of those parts is of the utmost importance to a race-horse in his running; it is, therefore, necessary that they should be, in breadth, substance, and length, of very superior dimensions. The hips should have a great breadth between them; and if they are a little coarse or projecting so much the better, provided such coarse projections are not in the extreme, or appear vulgar or unsightly. From the centre and posterior part of the loins to the top of the tail is called the 'croup,' and should be of great length; and, if it deviates from that of a straight line, it may be somewhat arched in the centre; the croup being thus formed gives great breadth to the top of the quarters, the length of which, from the croup down to the hock, cannot scarcely be of too great an extent, in order that there may be sufficient room here for the attachment of those broad, powerful, lengthy, and distinctly divided muscles on the outside of the quarters and thighs; and there should also be a similar portion of such muscles on the inside of the quarters and thighs; so that a man, who is a good judge, taking a posterior view, may observe how the horse is made. In this position he should be, as it were, struck by the appearance of the great breadth and length of the back part of the quarters, and as he moves his head to the right or left, the centre and outside of the quarters and thighs, and the swell of the muscles, should appear beyond a level with the hips. The upper part of the muscles on the inside of the quarters should appear quite close to each other, so that no vacant space should be visible between them, as that of an appearance of the horse being (if I may thus express myself) chucked up in the fork. Such should be the lengthy and muscular quarters of a well-made race-horse.

"The stifle-joint should be in a direct line under the hip, and the length from this joint to that of the hock cannot reasonably be too long, and the farther out of the angular or oblique position of the thigh-bone the better, so as to admit of the back part or projecting point of the hock appearing some distance out beyond the top of the hind-quarters; those parts being thus formed, admit of a very considerable lever for the main tendon here to act upon the tendon Achilles, which, like the flexor one of the leg, can scarcely be too large or too distinctly seen in its commencement, from the lower part of the quarter to its insertion into the posterior or projecting point of the hock, the *os calcis.* The hock should be broad and wide, with a clean lean appearance, and those soft parts which are occasionally the seat of through-pins and bog spavins, in a sound well formed hock, should appear more as cavities than as having the above-mentioned projections, and which are sometimes the cause of lameness. The hind-leg, like the fore one, should be short, broad, flat, and straight; the trifling angle formed by the hock should, together with the moderate obliquity of the pastern, bring the extremity of the toe nearly under the stifle-joint.

Action of the Race Horse.

As amongst the Egyptians the lion was the hieroglyphic of strength, so was the horse of agility; and truly nothing displays it more elegantly than he does, when in a state of liberty. In the race-horse, action, as in eloquence, is the next thing to substance; and *virtus in actione* should be the horse-breeders' motto. But the action of the race-horse is of a nature peculiar to his calling. He must not only possess great stride in his gallop, the result of great proportion in his limbs and moving levers, but also a quickness in repeating that stride, or he would lose in time what he gains in space. It is then when stride and quickness are united, that the fleet racer is produced; and in his race with Diamond, Hambletonian is asserted to have covered twenty-one feet at a stroke at the finish of it; and Eclipse is generally believed to have covered eighty-three and a half feet of ground in a second, when going at the top of his speed, which, by a calculation by Monsieur Saintbel, amounted to about twenty-five feet of ground covered at a stroke. Different ground requires different action; and the long striding horse may be beaten on a hilly, or turning course, by one of a smaller size, but with a shorter stride, which prevents the Newmarket courses being a certain criterion of a good runner at Epsom, which is very trying ground. The state of the ground, likewise, whether wet or dry, soft or hard, tells so much in a race, as often to give it to a horse very little thought of at starting, as was the case with Tarrare and Saucebox, winners of the St Leger, at Doncaster, in 1826 and 1855. The celebrated Euphrates, the winner of so many gold cups, and who ran till he was in his teens, was nearly a stone below his usual form, after even a hard shower of rain. This variation of fleetness corroborates our assertion, that the virtue of what is termed blood is mechanical, or that the excellence of all horses is mechanical, and that the smallest deviation from a true formation of the acting parts operates so powerfully as to render them, under certain exertions, nearly valueless.

Wind.

It is true, "speed wins the race;" but to make it available to the race-horse, it must be accompanied by endurance, or "bottom." A great promoter of this is clear wind, or freedom of respiration, the want of which makes the war-horse rebel in the manège, the hunter run into his fences, the draught-horse fall, as if he were shot, and the racer either stop, or bolt out of the course. In fact, when the organs of respiration are fatigued, all animals are nearly powerless. The cause of good wind may be distinguishable to the eye, and arises chiefly from depth in the forequarters, which implies a capacious thorax or chest. However wide a horse may be in his foreparts, he will not be good-winded unless he is, at the same time, deep. But still wind in the race-horse depends on something more—on the nature of his constituent and component parts, which, if in proper proportion, impart to him strength and agility, giving him that easy action which will not readily fatigue these organs of respiration; and so enable him to run on, when others, less gifted by nature than himself, are forced to slacken pace. The good effect of clear wind in a race-horse is in fact twofold; first, it gives him signal advantage in a race; and, secondly, horses thus organized require less work to make them fit to start.

The following passage on this point is worthy of remark:—"When the animal powerfully exerts himself, a more ample supply of pure blood is required to sustain the energies of life, and the action of the muscles forces the blood more rapidly through the veins; hence the quick and deep breathing of a horse at speed; hence the necessity of a capacious chest, in order to yield an adequate supply, and the connection of this capacity of the chest with the speed and the endurance of the horse; hence the wonderful relief which the mere loosening of the girths affords to a horse blown and distressed, enabling the chest to expand, and to contract to a greater extent, in order to yield more purified blood; and hence the relief afforded by even a short period of rest, during which this expenditure is not required, and the almost exhausted energies of these organs have time to recover. Hence, likewise, appears the necessity of an ample chest for the accumulation of much flesh and fat; for, if a considerable portion of the blood be employed in the growth of the animal, and it be thus rapidly changed, there must be provision for its rapid purification; and that can only be effected by the increased bulk of the lungs, and the corresponding largeness of the chest to contain them" (*Farmers' Series*, "The Horse," part vi., p. 182).

Certain thorough-bred horses would deceive an inexperienced observer as to the real state of their organs of respiration, by an appearance of difficulty of breathing, which in reality they do not possess. The term for this apparent defect is, in one instance, hard breathing, or high-blowing; and, in another, "cracking the nostrils." Of the first description was the celebrated Eclipse, whose breathing in his gallop could be heard at a considerable distance; and of the latter (still more common) may be reckoned many of the best racers of past and present days. Indeed, a race-horse cracking his nostrils in his exercise, and snorting well afterwards, are considered indicative of good-windedness. On the other hand, when a race-horse becomes a roarer, which is a common effect of a severe attack of the epizootie, called the *distemper*, he is rarely able to struggle in a race, although there have been several instances of winners under such very unfavourable circumstances.

Temper is a property of much importance to the race-horse, subject as he is to its influence under more trying circumstances than most other descriptions of horses. In the first place, his fine and nearly hairless skin, softened and cleansed as it is by frequent copious perspiration, is so highly sensible to the friction of the wisp and brush, as to induce him to try to rid himself of his tormentor by attacking the person who is dressing him, and thus becomes vicious in the stable. It will also be recollected that he is at this time perhaps in the very highest state of condition and good keep of which his nature is susceptible. On the race-course, again, he has often to encounter the (to him) unnatural sound of music, and many strange objects; perhaps two or three false starts before he gets into a race; and too often, when doing his best in a race, very severe punishment both by whip and spur. It is in his race, however, and chiefly in the last struggle for it, that the temper of the race-horse is most put to the test; and, if really bad, he either runs out of the course, to the great danger of his rider, and to the inevitable loss of his owner and those who have betted on his winning, or he "shuts up," as the term is, and will not head his horses. It is evident, then, that breeders should not send mares to stallions of known bad temper, as nearly all those propensities are found to be hereditary.

It would be absurd to draw a comparison between the English race-horse in training and the horse of the desert "educated," as Mr Gibbon eloquently says of him, "in the tents, among the children of the Arabs, with a tender familiarity, which trains him in the habits of gentleness and attachment." Nevertheless, we are inclined to believe that the tempers of many naturally quiet horses are made uncertain, and oftentimes decidedly vicious, by want of proper judgment, as well as good temper, in those also who have the management of them. Brutes, like men, demand a peculiar mode of treatment when we require them to do their utmost for us; and it is certain that this principle holds good in regard to both—namely, *that in general kindness gains its point, cruelty provokes resistance, and a proper degree of severity produces obedience.* The panther in the fable knew who fed her with bread, and who pelted her with stones; and we may be assured, that so noble and high-spirited an animal as the horse feels with acuteness sensations of pleasure and pain.

We often hear it asserted that the British thorough-bred horse has degenerated within the last few years, and is no longer the stout and long-enduring animal that he was in the bygone century, particularly during the last twenty years of it. We are inclined to believe that there is some truth in this. We do not think we have such good four-mile horses, as they are termed, as formerly, which we consider easily accounted for. They are not wanted, very few four-mile races being now run, even at Newmarket or in the country, and therefore a different kind of race-horse is sought for. It may, however, be true that the inducement to train colts and fillies, at a very early period of their lives, for these short races, has had an injurious effect on their stamina, and, consequently, on the stock bred from them. Formerly a horse was wanted for a lifetime, now he is cut up in his youth to answer the purposes of perhaps but one day—a system, we admit, quite at variance with the original object of horse-racing, which was intended to benefit the community, by being the means of producing, as well as displaying, the constitutional strength of the horse in its very highest perfection. Another cause may have operated in rendering thorough-bred horses less powerful than they were, or less capable of enduring severe fatigue. During the period of high weights and long courses, horses and mares were kept on in training until after they had arrived at the age of maturity, neither did they begin to work so soon; whereas now, no sooner have they won, or run well for some of our great three-year-old stakes, than they are put into the stud to produce racing stock, which is perhaps to be used much in the same manner as they themselves have been used, or, we should have rather said, abused. The amount of work which horses now get through at two years' old is enormous. Lord Alfred, for instance, ran twenty-four races at this age, and won nine; and Clothworker won twenty-nine out of fifty-nine; and Rataplan thirty-eight out of sixty-three races during two consecutive seasons. Zohrab, and Isaac and Naworth, also retained their racing powers for seven or eight seasons; and Alonzo, who began to race as a two-year-old in 1849, is still in good winning form in 1856.

But to return to the alleged alteration for the worse in the British race-horse. We admit the fact, that he is not generally so good at high weights over the Beacon at Newmarket, or any other four-mile course, as his predecessors were, whose descent was closer than his is to the blood of Herod and Eclipse, and the descendants of that cross, said to be the stoutest of any. Nevertheless he is, in his present form, more generally adapted to the purposes to which the horse is applied. He has a shorter but more active stroke in his gallop than his predecessors had, which is more available to him in the short races of the present time than the deep rate of the four-milers of old times; and as he is now required to start quickly, and to be on his legs, as the term is, in a few hundred yards, he is altogether a more lively active animal than formerly; and, as such, a useful animal for more ends than one. In former days not one trained thorough-bred horse in fifty made a hunter. Indeed few sportsmen had the courage to try the experiment of making him one. He went more upon his shoulders, as well as with a straighter knee, than the modern race-horse does, and required much greater exertion in the rider to pull him together in his gallop. All those sportsmen, however, who remember such horses as the late Earl Grosvenor's John Bull and Alexander must admit that in form and substance they were equal to carrying the heaviest weight across a country, and the last-mentioned horse was the sire of several very powerful, at the same time very brilliant hunters. But as it is action, after all, that carries weight, the thorough-bred horses of this day are not deficient in that respect, unless undersized; and there are more thorough-bred hunters at this period, and have been more for the last thirty years, than were ever known before. This improvement in action also qualifies the full-bred horse for the road; whereas formerly not one in a hundred was fit to ride off turf.

"The Druid," in his new work, *The Post and the Paddock*, after mentioning that the late Lord George Bentinck had thirty-eight horses in training one season, and that his losses on his colt Farintosh, in stakes and forfeits alone, reached L.3000, thus epitomizes the leading points of the turf as it is:—"Mr Mostyn's winnings in stakes are said to have been about L.22,500 in 1847, an amount which has, we believe, never been exceeded. In value the L.6325 Derby of 1849 still keeps the lead; while the L.3378 which was taken at the Doncaster Grand Stand in Stockwell's year is said to be the largest sum of the kind on record. The subscribers to the above Derby numbered 237, and the luckiest of handicaps was the Chester cup of 1853, when 131 out of 216 horses accepted. This cup also brought out forty-three starters in 1852, which is more than have ever been seen at the starting-post in the memory of man before or since the handicap era—that inevitable result of railway facilities for "getting a length" set in with such intensity. None of these "great facts" bear date in 1855; but taking Weatherby's *Calendar* as our guide, we may characterize the turf of that year as a vast institute for sport, comprising 144 meetings in Great Britain and Ireland, which were attended by 1606 horses, of whom only 680 were winners, fed by L.60,000 of added money, inclusive of the value of cups and whips, and diffusing L.198,000 in added money and stakes, "more or less."

Speed of the Race-Horse.

All animals in a state of domestication exhibit powers far beyond those that are natural to them in their wild state, and writers on the horse have advanced to the utmost verge of possibility, in recording the maximum speed of the English race-horse. Most of the instances stated by them, such as Flying Childers having run a mile in a minute, are unsupported by authority, and therefore not worthy of regard. That the horse, however, has ever been considered the swiftest beast of the forest, may be gathered from the frequent allusions to his fleetness by inspired as well as by heathen writers. Thus, the chariot-horses of Oenomaus, King of Elis, were said to be begotten by the winds, emblematical of their prodigious swiftness; and Homer represents the steeds of Achilles to be the produce of Zephyrus (the west wind, said to be the swiftest of any), and Podarge,

Race-Horse.

whose name signifies speed. Nor is Virgil far behind the rest in his encomium on the fleetness of his colt, which he makes to challenge the very whirlwind itself. As it is speed, however, that wins the race, it is most essential to the race-horse, provided it be accompanied by stoutness; and unless we wish to fly through the air like Pacolet on his wooden horse, we may be contented with the speed of the present English race-horse. One minute and forty-five seconds is considered first-rate time for a mile; and the one mile six furlongs, and one hundred and thirty-two yards, St Leger course, is done, on the average, by three-year-olds, carrying 8 st. 7 lbs., in 3 minutes 20 seconds. West Australian's Ascot cup race, in 1854, when he ran the very severe 2½ miles course with 8 st. 5 lbs. in 4 minutes 27 seconds, is the best modern time we have.

Expenses of a Breeding Racing-Stud.

Some persons must be breeders of race-horses, but whether to profit or loss, depends on various circumstances. Amongst them may be reckoned the following:—Judgment in selecting the parent stock or blood; conveniences for keeping the produce well and warm, and on land suitable to breeding; and plenty of money at command to enable a breeder to purchase mares of the very best racing families, and to put them to the best of stallions. When this is the case, we think breeding (we mean quite distinct from risk in racing) would seldom fail to pay, if the foals were sold off at weaning time, or even at a year old. The price fetched by the two hundred blood yearlings, which are usually brought to the hammer in England, averaged, during the racing seasons of 1854-55, about 127 guineas, which is calculated for all prices, from 10 guineas to 1000 guineas, or in the case of Lord of the Hills, 1800 guineas. Within the fifteen months which preceded this remarkable (1855) sale at Doncaster, to Mr S. Crawfurd, 1000 guineas, 1020 guineas, 1000 guineas, 1200 guineas, and 1400 guineas, were got for yearling colts in public and private; and 900 guineas and 810 guineas for yearling fillies. The average price at the royal sale of 1854 was 441 guineas for fourteen, many of whom were of the Orlando blood, which fetches a higher price than any other we have. No doubt, in all studs, great loss is sustained by a certain proportion of the young stock which promise to be small and not worth training; but here breeders are often deceived. For example, the late Lord Grosvenor sent Meteora, the best mare in England of her day, to Chester Fair, when two years old, to be sold for L.16, because she was considered as too small; and he also suffered Violante, the best four-mile racer of her day, to be sold, *untried*, for L.50, but fortunately purchased her again. The great prices, however, occasionally paid to breeders for some horses (4000 guineas, for example, to the Earl of Jersey for Mameluke, and 3500 guineas for Bay Middleton), make up for the loss inseparable from such as, by misshape, diminutive size, and casualties, are culled out, and sold for what they will fetch, which seldom amounts to much. Five thousand guineas was refused for Plenipo; and the greatest price ever given for a race-horse was 6500 guineas for the two-year-old, Hobby Noble, in 1851. We may, however, cease to wonder at such prices, when we find that the Flying Dutchman won his owner nearly L.20,000 in stakes alone, and that the winnings of himself and his half-brother, Van Tromp, who belonged to the same owner, amounted to nearly L.34,000. Cotherstone won, at three years old, L.12,765, West Australian, L.10,975, and Surplice, L.10,375.

Colour of the Thorough-bred Horse.

The prevailing colour of the thorough-bred horse is peculiarly elegant and chaste, being a bright bay, with black mane and tail, and black legs to correspond, although occasionally relieved with a small white star on the forehead, or a white heel. It is remarkable that what may be termed vulgar colours, such as light sorrel, or dun, or brown with mealy muzzle, are very seldom met with in the thorough-bred horse; and we know but one instance of the pie-bald, and very few roans.[1] Black is not common, nor approved of, although several of our best racers, almost all of the Trumpator blood, have been of that colour. The real chestnut prevails a good deal, and is quite equal to the bay in the richness and brightness of its hues. Such was the colour of Eclipse; and, as is the case with game-fowls, in the breeding of which there are instances of a reversion to the original colour, after fifteen descents, it is not uncommon for thorough-bred stock to be chesnuts, although got by a bay stallion out of a bay mare, or from a sire and dam of any other colour, provided the blood runs back to his, Eclipse's, source. Indeed, a small dark spot which that celebrated horse had on his quarter, has been frequently found in his descendants in the fifth or sixth generation. It is an old and trite saying, that "a good horse cannot be of a bad colour;" nevertheless, colours of horses are, to a certain extent, indices of their physical powers. Such has proved to be the case with men; and it was found in the ill-fated Russian campaign, that men of dark complexions and black hair bore the severity of the climate better than men of an opposite appearance to them. It is, however, rather a remarkable fact, that by far the greater number of eminent English prize-fighters have been men of light, not dark, complexion. The ancients reckoned thirteen colours of horses, giving the preference to bay (badices); and the dark bay, or "Jersey bay," is still the favourite English colour, though foreigners prefer a "black brown."

Race-Horse.

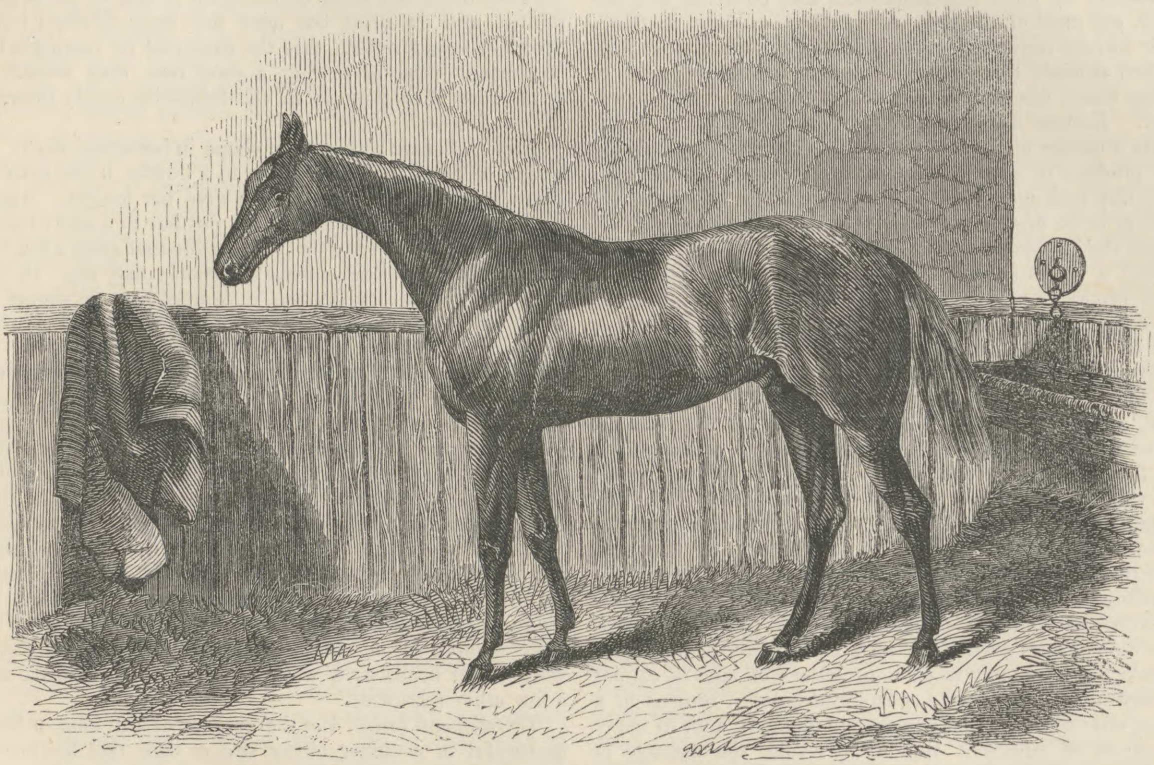
A second-rate description of racer was once very prevalent in England, known by the term "cock-tail," or *half-bred* horse, as he is called; but improperly so termed, because the stain in him is generally very slight indeed, and too often difficult to be traced. Many objections are raised by sportsmen, who are thorough racing men, and who wish well to the turf, against the cock-tail racer, and for very good reasons. In the first place, if really half-bred, he resembles the royal stamp upon base metal, for no half-bred horse is deserving the name of racer; and, secondly, what are called half-bred stakes, some of which are very good, have been the cause of a great many frauds being committed, by bringing horses to run for them under false pedigrees, which will ever be the case, from the great difficulty of proving a horse to be thorough-bred, whose dam may have been purchased by accident, or in some clandestine way, and still perhaps of pure racing blood. An animal is produced against which no half-bred horse, in the proper acceptation of the term, has a chance, and he sweeps the country of all the good stakes; and some such horses (Habberley and Combat, for example) have proved themselves superior to many of the thorough-bred racers of their year. But the breeding of horses for these stakes is anything but beneficial to the country, the great object of racing. It encourages a spurious race of animals, often possessing the faults of the blood horse without the strength and activity of the hunter, and it was for the latter description of horse that this stake was first intended. *Bona fide* hunters' stakes would be advantageous, if *open to all horses* bringing certificates of their having been regularly hunted throughout a season, but not merely ridden by a boy to see a fox found; and giving no allowance to the horse called "half-bred." Let the best hunter win, which would encourage the breeding of strong thorough-bred horses, which make the best hunters of any;—a fact no one who has ridden many of them will deny.

---

[1] See "*The Cocker,*" by W. Sketchley, Gent. London, 1814.

Weatherby's General Stud-Book.

To assist in the detection of spurious blood, and the correction of inaccurate pedigrees, is the chief purpose of this excellent publication, now increased to a seventh volume, and forms a part of every sportsman's library; but, unfortunately, many breeders who do not race are careless about entering their foals in it. "The Druid," in his recently quoted work, gives it as his opinion, that about 1550 blood mares annually bring 1150 foals to the birth in Great Britain. Taking 1851 as the basis of his calculations, he considers that about 1160 foals were born in that year, of which not 1100 were alive on the next new-year's day. Of these 574 ran in 1853, which number decreased in 1854 to 516, but in 1855 the remnant of that high-bred band only numbered 280.



THE HUNTER.

There is no description of horse which could be applied to so many purposes, racing excepted, as the powerful English hunter. Setting aside his own peculiar services in the field, he is fit to carry a man on the road, in the field of battle, and he answers for every kind of draught. Indeed, we are inclined to believe no horse would equal him in ploughing; and as for road-work on harness, either slow or fast, nothing could touch him, in a carriage properly suited to his powers. It is, however, no less true than singular, that out of a hundred sportsmen assembled at the meeting of a pack of fox-hounds, not half a dozen would be found mounted on horses which they themselves had bred. This arises from two causes: First, the greater part of them have not patience to await the arrival of a young horse at his best, and consequently sell the few they do breed, without giving them a fair trial; and, secondly, such has, of late years, been the prejudice against riding mares in the hunting field, that they have been chiefly left in the hands of farmers and yeomen, who are become the principal breeders of English hunters. Neither do hunters find their road direct from the breeder to the studs of noblemen or gentlemen. They generally go through the hands of an inferior country dealer, from whom they are bought by the principal London and country dealers, and sold by them to the sportsmen of the various hunts. There are, of course, exceptions to this proceeding. A great proportion of English yeomen and farmers are very excellent horsemen, and, as such, having the capability of making their young horses into hunters, and, distinguishing them by riding them afterwards with hounds, obtain now and then as high a price for them as they fetch after having passed through the hands we have described. It is, however, to be lamented that the last-mentioned description of persons, the breeders and trainers of young hunters, do not, for the most part realize such large prices as the first, although fully entitled to it, as a reward for their trouble and skill.

It is impossible to lay down any precise rules for breeding hunters, so many collateral circumstances being necessary to be taken into consideration. For example, Pennant, in his *Zoology*, says, "Our race-horses are descended from Arabian stallions, and the genealogy faintly extends to the hunter." From this we learn the interesting fact, that a wonderful change, within the last sixty or seventy years, has taken place in the form and character of this sort of horse, inasmuch as, in the opinion of some of the first of our English sportsmen, and such as put the powers of the horse to the most severe test, the hunter of the present day is not in his perfect form unless quite thorough-bred. This part of the subject we shall discuss hereafter; but as there are several of our hunting counties not at all suited to this description of horse, the thorough-bred hunter, and a large portion of our sportsmen who, some by reason of their weight, and others from prejudice against them, neither can nor will ride them, we may safely assert, that not more than a twentieth part of English hunters are at this time of quite pure blood. We will, however, set forth what we consider the best properties of the full-bred and the half-bred hunter, as he is called, as also the most probable means of breeding each kind to advantage; at the same time venturing an opinion, that, when their individual capabilities are put into the scale of excellence, the balance will incline to the former.

One great obstacle to the general success in breeding hunters is, not so much the difficulty of access to good stallions, but of making breeders believe that it would be their interest to send their mares to such as are good, although at an extra expense. Most rural districts, in other respects favourable to horse-breeding, swarm with covering stallions, the greater part of which have proved very bad racers; but which, falling into the hands of persons who are popular characters in their neighbourhood, and covering at a low price, get most of the farmers' brood mares sent to them, their owners never reflecting, as they gaze upon these misshapen animals, that nature will not go out of her course to oblige them, but that, in the animal creation, "like begets like." Neither does the evil stop here. So much is this made a matter of chance instead of one of judgment, should the produce of a mare sent to one of these bad stallions be a filly foal, and she proves so defective in shape and action, as to be unsaleable at a remunerating price, she remains the property of her breeder, and in time becomes herself a brood-mare. What, then, can be expected from such produce? Why, unless chance steps in and supplies the defect of judgment, in the first instance, admitting that she is sent to a better stallion than her sire was, by the procreative powers of the male so far exceeding those of the female, as to produce a foal free from the defects of the dam, another shapeless, unprofitable animal is produced. Nevertheless, in the course of time, perhaps this produce, if a female, however bad she may prove, is also bred from, and thus a succession of shapeless horses is produced, to the certain loss of the breeder, and much to the injury of the community. Under the most favourable circumstances, and with the aid of good judgment, we cannot consider horse-breeding to be a certain source of gain; yet there are many inducements to try it as one branch of rural economics. The money goes out a little at a time, or by degrees, and therefore it is suitable to such occupiers of land as cannot embark in more extensive speculations, and it returns in a lump, oftentimes at a most welcome moment, and, in many instances, of sufficient amount to render the average of former less profitable years sufficient to cover expenses, if not to leave a profit. There is likewise another inducement to breeding horses; we mean the interest inseparable from all human speculations, from which more than an ordinary return may be looked for, which is the case here; added to the nearly universal interest attached to the breeding and rearing of every species of domestic animals.

With respect to brood-mares designed for breeding hunters, we admit that circumstances, not always within control, have their weight. An occupier of land is possessed of a mare or two which he thinks *may* breed hunters, and having them, it may not be convenient to him to replace them by those which might be more likely to breed good ones. But the choice of a stallion is always within his control, and he should not spare trouble, and moderately increased price, in his selection. It is well known to all hunting men, that the stock of certain horses have been remarkable for making good hunters (President, Belzoni, and Sir Harry Dimsdale, for instance), and that there are such horses always to be found, on seeking for them. A few pounds extra, laid out by the breeder in putting his mares to such horses, were sure to be amply repaid; for the produce would be generally sought after and purchased, even previously to their being tried. Englishmen know of no such restrictions, nor do we wish they ever should; but the interference of the governments of several European states as to stallions for the use of their respective countries, reads us a useful lesson on this head; for it is well known, on the other hand, that a great number of stallions to which English hunting mares have been put, have been equally remarkable for begetting soft infirm stock, quite unequal to endure, for any length of time, the severe work of a hunter. It should also be borne in mind, that even a first-rate racer may not be a propagator of first-rate hunters. The former is called upon to exert his powers on very different grounds and under very different weight to the latter, and the action which may suit one may not suit the other. This accounts for the stock of certain thorough-bred horses, which were very indifferent racers, proving very excellent hunters. We have already given it as our opinion, that a cross of Arabian blood is a great desideratum in that of an English hunter, and we need not urge this point farther; but if breeders would reflect, that the expenses of rearing a bad colt equal those of rearing a good one, they would attend more than they do to the following nearly unerring directions:—

First, Observe similarity of shape in horse and mare. As length of frame is indispensable in a hunter, if the mare be short, seek for a stallion likely to give her length. Again, if the mare be high on her legs, put her to a short-legged stallion, and *vice versa;* for it is possible that even a hunter's legs may be too short, a racer's certainly may be. In fact, to form a complete hunter, it is necessary he should be more perfect in his shape than a racer, which will admit of imperfections that would quite disqualify the other.

Secondly, Look to constitution. As no description of horse endures the long-continued exertion that a hunter does, this is a point to be attended to. But it may be overdone. Horses of a very hard nature, very closely ribbed up, consequently great feeders, with large carcasses, seldom make the sort of brilliant hunter now the fashion in England. Besides, one of this description requires so much work to keep him in place and in wind, that his legs must suffer, and often give way when his constitution is just in its prime. Horses with moderately sized carcasses last longest; and, provided they are good feeders, will come out quite as often as they ought to do, and are invariably good winded and brilliant, if well-bred and of good form, with a few other requisites.

Thirdly, and *lastly,* Let the breeder of any kind of horse be careful in avoiding either sire or dam that has proved constitutionally infirm. As has been already shown on very high authority, perfect or defective conformation is not more likely to be the result of a proper selection of horse and mare, than disease to be inherited from parents that have been constitutionally diseased. We could name stallions whose stock have been blind; others afflicted with splints, curbs, and spavins, and a mare which produced three roarers by three different sires. But it may be said, that splints, curbs, and spavins, are the result of malformation of the parts. Granted; but avoid all such malformation which is quite apparent to the eye in a breeding stud. It may perhaps be carrying this objection too far, were we to say, we would not breed from a mare or horse, which had become groggy or lame in the feet, from diseased navicular joints. Had the feet been more vigorously constituted, perhaps such lameness might not have occurred; yet it is but too probable that here the predisposing cause may be traced to over-severe treatment, and not to constitutional defect. The choice of sires is by no means limited, as there are about 300 blood sires in the United Kingdom, at the service of the public, at all prices for blood mares, from 50 guineas to 2 guineas, or even gratis, if the mare is the dam of a winner. Birdcatcher (whose winners number 148), Touchstone, Melbourne, and Bay Middleton, are at the head of the senior division, and Touchstone has no less than 26 of his stock, headed by Orlando, at the stud. Beeswing was very successful as a brood mare; but the same cannot be said of many very high class mares who have worked hard for some seasons on the Turf. Barbelle, the dam of the Flying Dutchman and Van Tromp, left the turf early, and the dam of Alice Hawthorne and Rebecca never had a bridle on.

Next in importance to the judicious selection of sire and dam, is the rearing of the colt which it is intended should make a hunter. It was the remark of a gentleman who kept fox-hounds more than half a century, that "great part of the goodness of a horse goes in at his mouth;" and nothing is more true. Nimrod, in his *Letters on the Condition of Hunters* (p. 223, first edition), says, "It is my confirmed opinion, that unless a colt be what is called 'deformed,' it is in the power of good keep, exercise, and physic, to make him what is termed 'a fine horse,' and one which will sell for a large price, either for harness or the saddle. No one who has not witnessed it, is aware of the improvement in shoulders, thighs, gaskins, &c., from good old oats, accompanied by regular work and proper riding." Breeders of hunters may be assured that such is the case; and that it is of little use to breed colts with the expectation of their making first-rate horses, unless they keep them *very well* in their colthood. They should also be treated *as horses* at a very early age. They should be ridden gently, and by a light man, or boy, with good hands, at three years old, across rough ground, and over small fences; and at four they should be shown hounds; but they should only follow them at a distance, and after the fences are broken down; for, if put to take large leaps at that tender age, they are apt to get alarmed, and never make first-rate fencers afterwards. Above all things, avoid getting them into boggy ditches, or riding them at brooks; but they should be practised at leaping small ditches, if with water in them the better, in the middle of a field, the rider putting them at them in rather a brisk gallop. This gives them confidence, and, the natural result, courage. With respect to the use of the bar, and teaching colts to leap standing over it, the practice is now condemned, and the system of letting them become timber jumpers, by taking it, as it comes, in crossing a country, is preferred, the present rate of hounds not admitting of the time occupied in a standing leap.

Some sportsmen adopt, and we believe with good effect, what is termed the "circular bar." Every description of fence that a hunter is likely to meet with, is placed within a prescribed circle of ground, and in this is the colt lodged, the man who holds him standing upon a stage in the centre. As another man follows him with a whip, he is forced to take his fences at a certain pace; and, in a very short time, a good tempered colt will take them with apparent pleasure.

At five years old it is customary to consider a horse as a hunter; but we are inclined to demur here. It is true, that if a colt has been very well kept, on the hard meat system, he is enabled to go through a good day's work with hounds at five years old, being quite equal to a six-year old, which has been kept on soft food, and not sufficiently forced by corn; yet it is always attended with danger of injury to his joints and sinews, if not to his general constitution; and we cannot pronounce a horse to be a hunter until he has passed his fifth year. As muscular action, however, produces muscular growth, he should not be kept in idleness during his fifth year, but should be ridden to cover, or with harriers, before Christmas; and when the ground gets dry and light in the spring, a good burst with fox-hounds may not do him harm. We do not, however, consider any five-year old horse fitting or safe to carry a gentleman over a country, as he cannot be sufficiently experienced to take a straight line.

We have known some masters of fox-hounds who have preferred purchasing yearling colts, or weanlings, at Michaelmas, to breeding them for their own use.

There are undoubtedly certain advantages attending purchasing yearly colts, with the view of making hunters of them. Such only may be selected as appear calculated for the country they are intended to cross, and the weights they will be called upon to carry; whereas, were the master of hounds to depend on the produce of his own mares, he might be disappointed in being able to select the number he would require to replace, in due time, the vacancies which occurred annually in his stud. We should consider the sum of 35 or 40 guineas for a good colt, at weaning time, a fair remuneration to the breeder, and well laid out by the purchaser.

Previously to giving directions for the purchase of a full-grown hunter, we shall proceed to exhibit him in his highest form, although we are aware of the difficulty, on certain subjects, of conveying, clearly, an idea from our own mind to that of another. We shall, however, endeavour to make ourselves understood by describing each individual point. As to the form and shape of a hunter's head, as we do not ride upon it, it is not of much consequence, provided it be well hung on; and that is of the very highest importance, not only, as we have shown in the race-horse, on account of his respiration or wind, but unless it be so, he cannot be pleasant to ride. Not only must his jaws be wide, but when we consider that the head of a horse hangs in a slanting position from the extremity of the neck, and that the neck itself projects a considerable distance from the chest, on the muscular strength and proper formation of the neck must also depend whether a horse be light or heavy in hand, and consequently pleasant or unpleasant to ride. A weak or loose neck may not be so material, as we have before observed, to the race-horse; he is generally ridden in a martingal, and in that case always; add to which, his race is soon run. Nevertheless, we like to see the neck of the race-horse rise out of the shoulder with a tapering curve, in which case he is pleasant to ride in his gallop, and, if a hard puller, his jockey has much more power over him than if his neck were loose and low. But, in a hunter, the proper position of his head is a *point of the greatest moment*, as without it his rider cannot handle him properly at his fences; and if he be not a regular star-gazer, he is always dangerous to ride over a country. The proper junction of the head with the neck, and the carrying of it well or ill, depend chiefly on two particular muscles contained in the neck. The most important of these is called the splenius muscle, which constitutes the principal bulk of the neck above, and its action is sufficiently evident, namely, very powerfully to elevate the head and neck. The principal beauty of the neck, indeed, as well as the carriage of the head, depends on this muscle; and its ample developement is a point the sportsman should attend to in the choice of horses that are to carry him with hounds. A certain degree of muscularity of the neck is absolutely necessary in a hunter, and it is greatly promoted by good keep in colthood; also by delaying the period of castration till the second year, which should invariably be done, when the want of this muscularity is apparent in the first. It must, however, be observed, that there is a medium in this muscularity of the neck, although excess is the better extreme of the two; for when the neck of a horse appears, like that of a sheep, to rise out of the chest, and so far from being arched above, and straight below, is hollowed above, and projects below, such a horse is nearly worthless for any pleasurable purpose, as his head cannot, by any means whatever, be got into a proper place.

It has been said that a horse with a long neck will bear heavy on the hand. We do not believe that either the length of the neck, or even the bulk of the head, has any influence in causing this. They are both counterbalanced by the power of the ligament of the neck. The *setting on* of the head is most of all connected with heavy bearing on the hand; and a short-necked horse will bear heavily, because, from the thickness of the lower part of the neck consequent on its shortness, the head cannot be rightly placed. The head and neck, however, should be proportioned to each other. A short head on a long neck, or a long head on a short neck, would equally offend the eye.

Although length of neck in a hunter is not desirable, length of shoulder is indispensable. Horses have raced well with short upright shoulders; but it is impossible that one so formed, however good he may be in his nature, or even in his general action, can be a safe hunter, and for this reason: A hunter is constantly subject—by down-hill leaps, leaping into soft ground, and getting his fore-legs into grips or unsound ground—to have the centre of gravity thrown forward beyond the base of his legs; and it is more or less recoverable according to the length or shortness of his shoulder. By length of shoulder is meant obliquity of the scapula or shoulder-bone, by which the point of the shoulder is projected forward, and which, added to the obliquity of the scapula, enables the rider to sit considerably behind, instead of nearly over the fore-legs or pillars of support, which, on a short and upright-shouldered horse, he must do. One remark, however, must be made respecting the oblique shoulder. It is sometimes not sufficiently supplied with muscle, with which the upright shoulder generally abounds. We therefore recommend purchasers of young horses for hunters to give the preference to what may *appear* coarse shoulders, nay, even inclined to be somewhat round or flat on the withers, provided they are accompanied by the necessary and absolutely essential obliquity of the shoulder-bones.

The setting on of the arm—which should be strong, muscular, and long—is of much importance to a hunter. By the length of this part in the hare, as we have already observed, added to the obliquity of her shoulder, she can extend her fore-parts farther than any animal of her size; in fact she strikes nearly as far as the greyhound that pursues her, by the help of this lever. The proper position of the arm, however, is the result of an oblique shoulder. When issuing out of an upright shoulder, the elbow joint, the centre of motion here, will be inclined inward; the horse will be what is termed "in at his elbows," which causes his legs to fall powerless behind his body, and he is seldom able to go well in deep ground. There are exceptions, but they are rare. A full and swelling fore-arm is one of the most valuable points in a horse, for whatsoever purposes he may be required; and although we have occasionally seen hunters with light thighs carry weight well, we never have seen it so carried by horses deficient in their arms.

If sportsmen were to see the knee of the horse dissected, they would pay more attention to the form and substance of it than they generally do. It is a very complicated joint, but so beautifully constructed that it is seldom subject to internal injury. Its width and breadth, however, when considerable, are great recommendations to hunters, as admitting space for the attachment of muscles, and for the accumulation of ligamentous expansions and bands greatly conducive to strength. Below the knee is a point on which we will not say much here, as we have already alluded to it in our remarks on the race-horse; we mean the shank or cannon bone, and its appendages. It can scarcely be too short in a horse that has to carry a heavy man; round legs are almost sure to fail; those of the hunter should be flat, with the back sinews strong and well braced. This constitutes what sportsmen call a "wiry leg."

The fetlock is also a complicated joint, and very liable to injury. In a hunter it should be large and strong. But, as regards his action, the pastern is still more material, and also to his standing sound. Very few horses with short pasterns can go well in deep ground, and for this obvious reason: The action of the joint is destroyed by getting below the surface of the ground, and is of course sooner immersed than when it is longer. But a greater evil than this attends a short pastern; it is the predisposing cause of navicular lameness, particularly in horses carrying weight, owing to the foot being deprived of that elasticity which a longer pastern affords, and which consequently relieves the concussion on the foot coming to the ground in galloping and leaping, as well as on the hard road. Horses with short, and consequently upright pasterns, cannot be pleasant to ride, and they seldom stand many seasons' work. Excess in either should be avoided, but of the two a hunter is less objectionable from the extreme of length than of shortness in this most material part.

That the foot of the hunter should be wide, and not low or weak at the heel, is also obvious to the meanest capacity, independent of its being the form most conducive to health. The nature of the ground he has to travel over requires at times the widest base he can present to it as a foundation for his great bulk, and thus the farmer carries out his manure upon tender land in a broad cart. Xenophon relates that certain people of Asia were accustomed, when snow lay deep, to draw socks over the feet of their horses, to prevent them sinking in it up to their bellies; and we know why an ox sinks less in soft ground than a horse does. It is because his foot enters it expanded, by means of the division of the claws, and when he draws it out it is contracted. The foot of the hunter, however, should not be too wide, or it may operate against his speed.

The position of the fore-legs of the hunter admits of more latitude than that of his hinder ones, or indeed of any other part of his frame. We have seen brilliant hunters standing in all positions and postures as regards their fore-legs. Some very much over the knees, that is, with the knees bent and projecting outward; many upon very twisted fetlocks, turning the toes out; and a few, though only a few, turning the toes in. In the human frame, a certain squareness in the position of the feet is consistent with strength, as we see in the statues of Hercules, but the lightness of a Mercury is indicated by the direction of the toe outwards. This is to a certain extent the case with the horse. Although, if measured by the standard of perfection, his toe is required to be in a direct line with the point of his shoulder, yet we have seen and heard of some of the speediest and best racers and hunters, the position of whose fore-feet have deviated considerably from this supposed essential line; but the inclination of the toe outwards is so common in horses used for these purposes, that it can scarcely be called a fault. Indeed, some persons argue that a leg so placed affords a broader base to the superincumbent weight than when quite in a line with the shoulder, that is, provided the twist arises from the fetlock, and not from the setting on of the arm. Be this as it may, we are well assured that, provided the hinder legs and quarters are good, a hunter will admit of a considerable deviation from the true line in the fore-legs, and carry his rider brilliantly. It is well known that a much more twisted fore-legged horse could not well be seen than the celebrated Clipper, for many years said to be the most brilliant hunter in Leicestershire; and one of the best hunter-sires in Shropshire had this deformity.

But there is one portion of the fore-quarters of the hunter to which a rule must be applied that will not admit of an exception: he must be deep in his chest or brisket, that is, from the top of the withers to the elbow. Numerous are the narrow, but deep horses, in their "girth," as the term is, that have carried heavy weights in the first style with hounds; but no matter how wide a horse may be, if he have not depth he cannot carry weight, and is very seldom a good-winded horse, even under a light man. One of the greatest compliments, then, that can be paid to a hunter at first sight is, that he appears 2 inches lower than he really is. Such, however, is the case with horses whose growth has been forced in their bodies by good keep when young, and thus they come under the denomination of "short-legged horses," so much esteemed by hard riders. They are likewise, for the most part, better leapers than such as have less growth in the body and stand upon longer legs.

We have before observed, when speaking of the race-horse, that large bone is not required in his cannon or shank (the part from knee to fetlock), neither is it in the hunter. The real power of all animals is in the muscles, sinews, and tendons; and the leg best calculated to carry weight and endure to a good old age is that in which the bone is small, but of a dense and perfect texture, and in which three convexities can be very plainly distinguished, namely, the bone, the elastic ligament behind the bone, called the sinew, and, behind that, *the flexor tendons, large, round, and strong.* The rare combination of strength with lightness is here beautifully displayed, and is one of the many instances which might be produced to show how nature delights to work with the least possible expense of materials.

The hunter should have length in his shoulders and quarters, and to a certain extent also in his back. It is true that horses with short backs carry weight best up a steep hill, which, as that is the worst method in which this animal can employ his strength (in man it is the best), shows that heavy men should ride short-backed horses. For hunters, however, that are ridden in our best hunting countries, which, previously to being laid down in grass, were thrown up by the plough into high ridges, with deep furrows, must have *moderate* length of back, or they cannot go smoothly over such ground. Good loins, with width of haunch (the *vis a tergo* being so necessary in leaping as well as galloping on soft ground), need scarcely be insisted upon; and we now proceed to the hinder-legs, the proper or improper form of which makes the difference between a good or bad hunter, if a horse with badly formed hinder-legs can be called a hunter at all. But a horse with short, straight, and weak thighs, cannot make a *good* hunter. Even admitting that they are not weak, but short and straight, yet the objection remains, because he cannot, in the latter case, be pulled together in his gallop, nor have his stride collected to enable him to take his fences properly; and, what is not generally known, he is almost certain to be a hard puller. Indeed, some good judges go so far as to assert that horses with straight hinder legs never have good mouths, and there is much truth in the remark, as their form will not admit of their being "pulled together," as the horseman's term is, in their quick paces, and without it no horse is safe. A long and muscular thigh, then, with a clean well-placed hock, is one of the most material points in a hunter, and also one by which the duration of his services may very nearly be measured; as when much out of the true form, either inclining inwards, like the cow, or outwards, like the bandy-legged man, disease is almost certain to attack this very complicated but beautifully contrived joint, when put to severe exertion, especially in soft ground. The shank bone of the hinder leg, below the hock, ought to be equally well supported by sinews and tendons with that of the fore-leg; and the pastern of the hind-leg should resemble that of the fore-leg, moderately long, strong, and oblique.

But such is the paramount importance of the hock in the hunter, that we transcribe the following admirable description of one most material point in it (from part ix. of *The Horse*, Farmer's series, p. 272):—"The most powerful of the flexor or bending muscles are inserted into the point of the hock or the extremity of the *os calcis;* and in proportion to the projection of the hock, or, in other words, the length of this bone, will two purposes be effected,—the line of direction will be more advantageous, for it will be nearer to a perpendicular; and the arm of the lever to which the power is applied will be lengthened, and mechanical advantage will be gained to an almost incredible extent. Suppose this bone of the hock to be 3 inches in length, the joint formed by the *tibia* and the *astragalus* is evidently the centre of motion, and the weight concentrated about the middle of the shank is the obstacle to be overcome. If the weight be four times as far from the centre of motion as the power, a force equal to four times the weight would raise it. It is, however, here to be remembered, that it is not merely the weight of the leg which is to be raised, but the weight of the horse, for the time resting upon the leg, and that weight to be propelled or driven forward. At what shall we calculate this? We may fairly suppose that the muscles, whose tendons are inserted into the point of the hock, exert an energy equal to 4000 lb. Let us further suppose that an inch is added to the point of the hock, which will be an addition of one-third to its length; a muscular power of less than 3000 lb. will now effect the same purpose. The slightest lengthening, therefore, of the point of the hock will make an exceedingly great difference in the muscular energy by which the joint is moved, and a difference that will wonderfully tell in a long day's work. On this account, the depth of the hock, or the length of the bone of which we are speaking, is a point of the greatest importance. There is, however, a limit to this. In proportion to the length of this bone, must be the space which it passes over, in order sufficiently to bend the limb; and in that proportion must be the contraction of the muscle, and consequently the length of the muscle, that it may be enabled thus to contract; and, therefore, if this bone were inordinately lengthened, there would require a depth of quarter which would amount to deformity. A hock of this advantageous length is, however, rarely or never met with; and it is received among the golden rules in judging of the horse, that this bone of the hock cannot be too long."

Hunters which carry very heavy men cannot excel in the field, unless they exhibit those just proportions in their limbs and all the moving levers necessary to produce full liberty of action, but not too long a stride. Well placed hinder legs, with wide hips, well spread gaskins, and great depth of chest, are essentials, and as much of the *vis a tergo* as is consistent with a not unsightly back, commonly called "hog-backed." Well knit joints, short cannon bone, moderately oblique pasterns, with rather large feet, are not only points from which great physical powers may be expected, but they are necessary to the duration of them in the horse we are now alluding to. As, however, it is an axiom in the animal creation that the parts which add to strength diminish swiftness, hunters to carry more than 16 st. well with hounds, at the pace they now run, are always difficult to be procured, and ought to command good prices. The stamp of animal most approved of for this purpose is the short-legged, thick, but well-bred horse, not exceeding 16 hands in height, but appearing to the eye half a hand below that standard. As for his general appearance, it is "handsome is, that handsome does," in this case; and we must not look for beauty in all his points.

Having now described each individual external part of the horse essential to his being a good hunter, we shall, in a few words, exhibit him to the reader's view in what we consider his best form. He should have a light head, well put on, with a firm, but not a long neck; lengthy, and consequently oblique shoulders, with very capacious chest, and great depth of girth; a long, muscular fore-arm, coming well out of the shoulder, the elbow parallel with the body, neither inclining inward nor outward; a short cannon or shank, with large tendons and sinews, forming a flat, not round leg; an oblique pastern, rather long than short, and an open circular foot; the back of moderate length, with well-developed loins and fillets, and deep ribs, making what is termed by sportsmen a good "spur-place." From the loins to the setting on of the tail, the line should be carried on almost straight, or rounded only in a very slight degree. Thus the haunch will be most oblique, and will produce a corresponding obliquity in the thigh-bone, which formation is peculiarly characteristic of the well bred horse. The dock of the tail should be large, the buttocks close together, and the fundament small, and somewhat resembling the front or eye of the pippin apple. The thighs should be muscular and long, rather inclining inwards, with large lean hocks, the points appearing to stand somewhat behind the body, which will bring the lower part of the hind-leg, or shank, under it. The shank, fetlock, and pastern of the hinder-leg, should exactly resemble those of the fore-leg, as also should the foot. The legs should appear short, from the great depth of chest, and well-proportioned substance of the body, or middle-piece.

The stature of the horse is no more absolutely fixed than that of the human body, but a medium height is considered as best for a hunter, say 15 hands, 2 or 3 inches. For one good horse over this height, there are a hundred under it. In fact, there are, in the operations of nature as well as of art, limits which they cannot surpass in magnitude, and no very large animal has strength in proportion to its size. That the horse has not, the pony affords proof, if any other were wanting. Even the heaviest weights find horses about the height we have fixed upon best calculated to carry them. There have been many extraordinary instances of horses, little more than 14 hands high, being equal to the speed of hounds over the strongest counties in England, for example, Mr William Coke's "Pony," as he was called, many years celebrated in Leicestershire, and Mr Green's "Piccolo;" but they are not pleasant to ride, by reason of the fences, when high, appearing higher to the rider than when he is mounted on a taller horse.

Temper and mouth are essential points in a hunter. The former adds much to his value, not only as it contributes to the pleasure and safety of his rider, but a horse of a placid temper saves himself much in a long day's work with hounds, and especially when there is much leaping. Indeed, fretful horses are proverbially soft, and not generally to be depended upon at a pinch, which caused Shakspeare to make them the symbol of false friends. Thus Julius Cæsar exclaims,

> "Hollow men, like horses, not at hand,
> Make gallant show, and *promise* of their mettle;
> But when they should endure the bloody spur,
> They fall their crest, and, like deceitful jades,
> Sink in the trial."

A hunter should have courage, but nothing more, to make him what he is required to be, namely, not afraid to leap at any fence his rider thinks proper to put him at. His mouth will depend upon two things; first, upon the judgment of the person who breaks him in, in his colthood, and, secondly, upon the position of his hinder legs, but chiefly upon the first. It ought to be endowed with so great sensibility, that the slightest motion of the bit should give him warning, and direct his course, which is significantly implied by Horace, when he said, "the ear of a horse lies in his bridle." It is true, that what we call the "mouth" of a horse, is an artificial feature, at all events, a figurative term for his being easily acted upon by the bridle; but it is a point of the utmost importance in a hunter. Without it, in short, he is absolutely dangerous to ride; for although the skill and power of his rider may prevent his running away, yet he is always in danger of being placed in some unpleasant situation or other by him. In the first place, he cannot be a large fencer, nor safe at all sorts of leaps, if he will not suffer his rider to pull him together, to collect him for the effort of rising at them. Secondly, he is as dangerous in going through gates only partly opened. Thirdly, if the horse immediately before him should fall at a leap, he is very apt to leap upon him, or his rider; and, lastly, his strength is sooner exhausted than that of a horse, perhaps not naturally so good, which is going quietly, and within himself, by his side.

No doubt many of the ancient writers were good judges of horses, although they were deficient, compared with the moderns, in availing themselves of their highest capabilities. Were a purchaser of a hunter to look no further than the first chapter of Zenophon *περι ἱππικης*, he would find hints that would be well worthy his attention; and nothing can be more expressive of the evils attending a bad mouth, in a horse of this description, than the following sentence from Pliny, "Equi sine frænis deformis ipse cursus, rigida cervice, et extento capite, currentium," which may be thus translated:—The career of a horse without a bridle is disagreeable, carrying his neck stiff, and his nose in the air. When we consider how often it is necessary to pull up, or to turn a horse very short in crossing inclosed countries, the value, even on the score of comfort, of a good mouth cannot be too highly appreciated by the sportsman.

We now come to the action of the hunter, which, after all, is the main consideration. He should have energy in all his paces, but he may have too much of what is generally called action. Nothing conveys to us a better idea of that which is adapted to his business, than the concluding sentence of a huntsman of former days, when describing to his master a capital run with his hounds. "The old mare," said he, "*carried me like oil.*" The action of the hunter should be *smooth*, or it will not last. His stride in his gallop should be rather long than otherwise, provided he brings his hinder legs well under his body; and the movement of the fore-legs should be round, but by no means high. Above all things, there should be no "*dwelling*," as it is called, in the limb, coming to the ground; a great obstacle to speed, but often the accompaniment of excessive action in the fore-legs. But the test of action in the hunter, is in what sportsmen call "dirt," that is, in soft, tender ground, or when passing over such as appears dry on the surface, but is not sufficiently so to bear his weight. It is not exactly in the power of the best judges to determine whence this peculiar excellence, which some horses possess over others apparently well-proportioned, arises, for which reason the eye should never be depended upon in the selection of horses for the field. Wisdom here can only be the produce of experience; and many sportsmen have paid dear for it on this particular point. In fact, nothing next to ascending steep hills under great weight, puts the physical powers of a horse to so severe a test as carrying a heavy man, at a quick rate, over a country that sinks under him at every step. Mere strength alone will not do it. It must be the result of a combination of strength with agility, good wind, and speed, to produce which the most perfect arrangement of the acting parts, although the exact symmetry and proportion of them may not be exactly discernible to the eye, are requisite, and, we may be assured, are present. As the beauty of all forms is, in great part, subordinate to their utility, a horse of this description, that is, one which can carry sixteen stone well up to hounds in any or in all countries, at the rate they now run, not only, as has before been observed, commands a very high price, but, to a person who loves to study nature, presents a feast to the eye.

A hunter should be what is called very quick as well as very fast; by which is implied, that he should not only have great speed, but that he should be very quick in regaining his speed after taking his leap, or being pulled up from any other cause. One so gifted will cross a country, especially a close one, in less time than one that is more speedy, but not so "quick on his legs," as jockies term it. It is also very agreeable that a hunter should be safe in his slow paces on the road; and, if a fast trotter, he relieves himself by changing the action of the muscles, when the pace of hounds so far abates as to allow him to break into a trot.

Leaping.

One of the greatest accomplishments in a hunter is being a perfect and safe leaper. The situation of a sportsman riding a horse that is "uncertain," as the term is, at his fences, may be compared with that of the philosopher whom Cicero describes in his Tusculan Questions (5, c. 21) as seated on the throne of Dionysius, gazing upon the wealth and splendour that surrounded him, with a naked sword suspended over his head by a single thread. But a horse following hounds often leaps under very great disadvantages, which accounts for the numerous falls sportsmen get. Putting aside the labour of rising from the ground, which, to the horse, with a weight on his back, must be great, from the earth's attraction and the body's gravity, he has often to take his spring without any fixed point for support; whereas, in most other cases, leaping takes place on a fixed surface, which possesses the power of resistance in consequence of its firmness. Nevertheless, although the surface yield to a certain degree, leaping can still be performed, notwithstanding the retrograde motion of the surface produces a great diminution in the velocity of the leap, compared with that which is made from firm ground; and the velocity is always greater in proportion as the resistance is perfect. Thus it is, that we find horses able to cover much greater obstacles in Leicestershire, and the other grass countries, where the taking off for the leap is generally good and sound, than they can cover in ploughed and marshy districts, where they have not that advantage, from the less firm state of the soil. We shall now endeavour to point out the form most likely to constitute a good leaper.

The very worm that crawls on the ground first carries its contraction from the hinder parts, in order to throw its fore parts forward; and it is chiefly from the *vis a tergo*, or strength of back, and hinder quarters, that the power of leaping in a horse is derived. It must, however, be admitted that oblique shoulders give him a great advantage, by enabling him to extend his fore quarters; but if his loins be loose and weak, and his hinder legs ill placed, with weak hocks, he cannot make, in any one's hands, a safe and perfect leaper. But the position of his head has something to do with it. A plank placed in equilibrio cannot rise at one end unless it sinks at the other; and although a horse in light harness cannot, for appearance sake, carry his head too high, provided he be obedient to the rein, the hunter should carry his low. A colt, running wild, never raises his head when he leaps, but rather lowers it, and so should the hunter; and he is always less liable to fall in galloping over a country when he carries his head low; likewise, in horses with lengthy shoulders, the seat of the rider is rather benefited than injured by it.

The sort of fence that stops hunters more than any other description of obstacle, is a wide brook; and, like all other wide places, it takes a good deal out of him, if he clears it. Lengthy horses are the best brook jumpers; but they require good loins and hinder quarters as well, and, above all things, *courage*. Unless a horse takes a wide brook in his stroke, he is almost sure to be in it; for which reason he is generally ridden fast at it, and, for the most part, not allowed to see it till he comes close to it. Immense space has been covered by horses when jumping brooks, particularly when there has been a difference of elevation of the banks in favour of the horse. We have heard of thirty feet and upwards from hind foot to hind foot; but half that space *in water* is considered a good brook, and even if the banks are sound, stops a great part of the field. When unsound, it requires a horse coming under the denomination of a "good brook-jumper" to clear it without a fall, and particularly if towards the end of a run.

To be a good timber leaper is a great desideratum in a hunter, although many horses are great timber leapers, but, from their form, can never make good hunters. It only requires a short backed, truss-horse for this purpose; and he can dispense with the general length so necessary to the complete hunter. Good and well-formed thighs, however, are necessary. For those hunting countries, such as Cheshire, where the hedge is generally placed on a bank or "cop," as it is there styled, rather a short but very active horse performs best. But he must be very good in his hinder legs, and very quick in the use of them. Wall jumpers come within the same class with timber jumpers as to make and shape.

There is one faculty in which the horse is wanting, that would, if he possessed it, give him a great advantage in leaping. In the human species, the power and influence of feeling are inherent, in a great degree, to the very tips of the fingers; but the horse has no proper organ of feeling or touch. When a man takes his spring for a leap, or leaps on the top of any substance, he has a distinct and certain sense or knowledge of the nature of the ground from which he has sprung, and of the substance on which he has alighted; but, from the insensible nature of the horse's hoof, such feeling is, in a great measure, denied to him, and indispensably so too. Still, however, there are a few instances upon record of horses going very well over a country even after having undergone the operation of neurotomy, by which all sensibility, from the fetlock downwards has been destroyed.

The *necessity* for the thorough-bred horse in the field is belied, by the experience of all unprejudiced sportsmen, and in Leicestershire, where the best studs are to be found, very many of the hunters have a bend sinister in their escutcheon. But this perhaps arises from three causes. First, there is a difficulty in procuring full-bred horses to carry even moderate weights, and speed is but a second attribute to a hunter. He must have sundry other qualifications, and the most prevailing objections to the thorough-bred horse are generally these: He is apt to be deficient in substance to carry high weights over rough and deep countries, without trespassing too much on the virtue of his high descent. Secondly, he is inclined, and especially if he have been trained, to be shy of facing rough and thorny fences, by reason of the delicate nature of his skin, rendered so by repeated sweats in clothes, when in training. It often happens, indeed, that even the cheering influence of hounds, which has so much effect on other horses, will not induce him to take them. In fact, which may appear extraordinary, he does not appear to have in the field the courage of the half-bred horse. Lastly, his feet are apt to be small, in which case he sinks deeper in soft ground than does the lower-bred horse, whose feet are larger and wider, and thus suffers more than the latter does, in crossing a deep country. As for his powers of endurance under equal sufferings, they doubtless would exceed those of the cocktail, and being, by his nature what is termed a "better doer" in the stable, he is sooner at his work again than the other. Indeed, there is scarcely a limit to the work of full-bred hunters of good frame and constitution and temper.

A sportsman, partial to thorough-bred hunters, should either breed them, or purchase them, not exceeding two years old. If he breeds them, he should select large and bony mares, putting them to horses who have hunting action, such as Tramp had; and, if he buy them, it will be his fault if he do not buy those of the right stamp. From their never having been trained, but ridden over rough ground in their colthood, they would have freer and higher action, and, when castrated at a proper age, would very rarely fail making first-rate hunters. The reason for subjecting them to the enervating operation of castration is, that by far the greater number of entire horses, used as hunters, are either dangerous in a crowd, and when pressed upon in gateways; or given to refuse their fences, when they feel themselves somewhat distressed; and, if once well tired, are not to be depended upon afterwards. The late Earl of Lonsdale's Julius Cæsar was, nevertheless, a good instance to the contrary; and so was Mr Arkwright's Dr

Faustus. If free from these defects, they are doubtless superior to either geldings or mares.

Purchase of a Hunter.

Although it may not be necessary that a person should be perfectly acquainted with the mechanical structure of the horse's frame, according to the laws of nature, to render him a good judge of a hunter, yet, fortunately for such as have them to sell, vast numbers of persons purchase hunters from very slight experience of them, regardless of the proverb of, "he hath a good judgment who doth not rely on his own." There is also another proverb, prevalent, we believe, in Spain, which well applies here: "He that would buy a mule without a fault must not buy one at all;" and, although faultless hunters may be as rare as faultless riders of them, we will offer a few hints to a person in the act of purchasing one, addressing him in the colloquial style.

First, bear in mind the country you are about to hunt in, whether flat, hilly, firm, soft, open, or inclosed, and refer to the remarks we have made on the sort of horse we have adapted to each; only be assured that in an open country, especially if a hilly one, nothing has a chance with a thorough-bred horse, in good form, and not over-weighted. Secondly, consider well your weight, and be sure to have at least a stone to spare. A light man on a light horse throws away all the advantage of being light, and can go no faster, or leap larger fences, than a heavy man on a strong horse, *for strength will be served.* Until you try him, it is hard to say what horse will make a hunter, but the following indices may induce you to try him:—If he appear well-bred, with a loose, bright skin, which may be called his complexion; observe that his hair does not stand hollow from the skin, particularly about the poll of his neck. If you find him standing over a good deal of ground, it is a sure sign that he has got length where it ought to be; not in the back, but from the obliquity of his shoulders, and the arm being set on at the extreme point of his shoulder, which so much contributes to the act of extension of the fore parts in galloping, leaping, and clearing grips. Next examine minutely his thighs and hocks, being especially careful to observe the position of the point of the hock bone. Above all things, avoid a short, or an overtopped horse. The former will never carry you to your satisfaction, however good he may be in his nature; and the latter, from being too heavy for his legs, will seldom last many years. As for the minor points, common observation alone is wanting. Have his head placed in such a situation as will enable you to satisfy yourself that he has perfectly organized eyes, free from incipient cataract, sometimes rather difficult to be detected; and as for his age, there are but two ways of satisfying yourself on that point. By his teeth till about eight years old; afterwards by the state of his legs, which are, in fact, the best test of his value, the best proof of what he has done, and the sure source of speculation as to what he may hereafter be expected to do. Observe, also, his joints, that no material injury has been done to them by blow, &c., and that they are strong.

But the purchaser of a hunter must not trust to his eye. Neither must he be satisfied with him, how well soever he may gallop with him upon *sound* land. It is the peculiar excellence of "going well through dirt" that renders a horse valuable for all our best hunting countries; and no man can assure himself that a horse has this peculiar excellence, until he puts him to the test. The best method of doing it is this: The rider should put him along at a good pace, with a slack rein, upon sound ground, letting him find himself all at once upon that which is soft and holding. If, on quitting the former, he cringes more than might be expected under the weight, and shortens his stroke much, he must not purchase him for a hunter. He may go well over a light, down country, but he will never distinguish himself over a heavy one, as he will be going in distress, when other horses are going comparatively at their ease. Horses possess gradations of excellence in this natural qualification, or gift, more than in any other, but in it consists the *summum bonum* in a hunter; inasmuch as, whatever may be his other good qualities, they are all useless, when the acting parts are, from this cause, deep ground, easily over-fatigued. With regard to his wind, he must not judge hastily of that, in a horse not in work. Should he not perceive anything like whistling in his respiration when he puts him along at a quick pace, and his chest is capacious and deep, and his head well set on, he is not to reject him in case he appears blown by a short gallop. Condition and work will rectify that; but many a good hunter has been rejected on this account, by persons not taking into consideration the state of his bodily condition, in a trial of this nature.

The price of the hunter varies with the times, and, no doubt, is as much regulated by the price of wheat as the quartern loaf is. During the war prices, the sum of 1000 guineas was occasionally given, and that of 500 guineas frequently. From 150 guineas to 300 guineas now commands a first-rate hunter. But first-rate horses, in all ages of the world, have ever produced extravagant prices; and it is recorded of Alexander the Great, that he gave four Roman talents for the celebrated Bucephalus, by mounting which the young prince gave the first token of the skill and daring which carried him through so many difficulties.

THE HACKNEY.

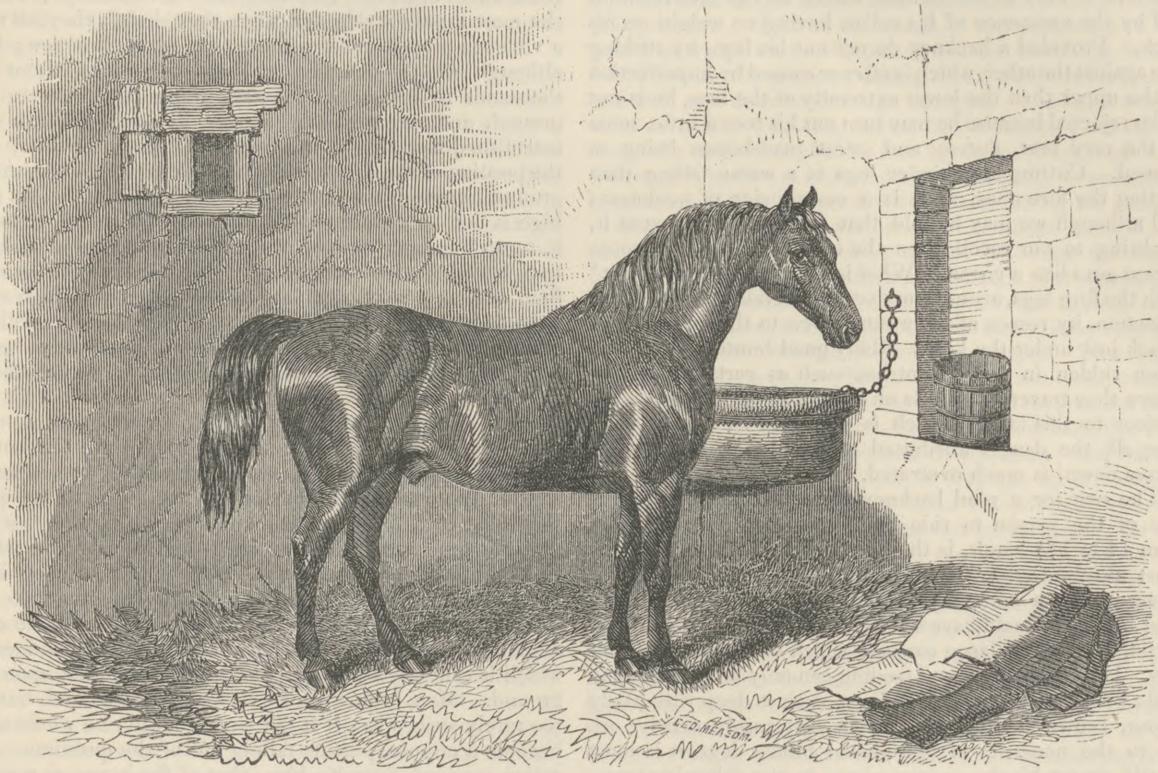
Under this term are comprised the following:—The Cover Hack, the Pack Hack, the Lady's Horse, the Roadster, the Cob, the Galloway, and the Pony.

The difficulty of procuring really good hacks is admitted by all persons who have kept them for the various purposes of either business or pleasure, and for the following obvious reasons. First, very few people try to breed hackneys, therefore, although we require them to be nearly perfect in shape and action (and perfect they should be to be "really good hacks"), they may be said to be failures in the breeding stud after all. Secondly, by reason of their appearing to be failures in their colthood, they are not forced into good shape, as more promising young horses are, by high keep and care. Lastly, if a man has a really good hack, he is unwilling to dispose of it at the price generally given for such animals. But a question arises, What is a good hack? It cannot be answered but with reference to another question, namely, What description of person is he to carry? The horse that a sober citizen of London or Edinburgh would call a perfect hackney to carry him to his country seat, would not be worth five shillings to a Newmarket or a country jockey, or as a cover hack to a Leicestershire or Warwickshire sportsman. We will commence, then, with the cover hack, and describe the others in their turns.

The cover hack of the present day is very difficult to be procured, because he must unite, with the good qualities of the roadster, the requisites and accomplishments of the hunter. In fact, he must be a hunter in miniature; and after all, the form of the hunter is the best calculated for a roadster. He must be fast in all his paces, able to gallop well on deep or soft ground, and equal to carrying his rider over moderately sized fences; and if taught to leap timber, standing, his value is proportionally increased. But, above all things, he must go from 12 to 15 miles in the hour, when wanted, without showing any symptoms of distress; and he is too often unnecessarily called upon to perform much more than this, by his owner delaying the period of his leaving home in the morning, for the purpose of

Hackney.

meeting hounds. It may also be observed, that it is not every sportsman who keeps two cover hacks, although he may keep six or eight hunters; and it often happens that the cover hack does more work than any horse in the stable, although in justice it should be stated, that the same care in the stable is now taken of him as of the best hunter in it.



Unless to carry a great weight, the cover hack should be all but thorough-bred, if he cannot be procured of quite full blood; with excellent legs and feet, lengthy and elevated shoulders, and with a susceptibility of mouth that will not only enable his rider to keep him well on his haunches, to guard against danger when going fast on all sorts of roads, but as tending to lessen the fatigue of riding him; and the strength of his rider should be reserved for his day's diversion after hounds. The chief pace of a cover hack should be the canter, and his temper should not be overlooked, for if fractious, and a puller, he will add much to the fatigue of a severe day's sport. A horse of this description, nearly 15 hands high, young and sound, will command from L.60 to L.100. The other points essential to a good road hackney, which will be noticed hereafter, apply equally to the cover hack.

The park hack of the present day is the race-horse in miniature. To be quite *à la mode*, he should be thorough-bred, with a very neat head, beautifully set on, and a switch tail; and so well bitted as to be ridden with a slack rein. He should have much liberty in his walk, which, and the canter, should be his chief paces. He must have great obliquity of shoulder, with a corresponding true formation of hinder quarters, and above all, the well-bent hinder legs; in which case, if the position of his fore legs enable him to put his feet down properly, which will be explained in describing the general action of the hackney, he will be, if good tempered, and not given to fret, the perfect park hack.

The lady's horse is, after all, the most difficult to obtain, because he ought to approach very near to perfection. His paces, mouth, and temper, should each be proportioned to the power and capability of his rider; and he should be proof against alarm from either noises or sights, which otherwise might cause him to run away. This description of horse should likewise be well bred, as in that case his action will be easier, and his appearance and carriage more in character with the generally elegant appearance of his rider. His pace should be the canter; the trot causes an ungraceful movement in the person of a woman, to enable her to rise to it; and if she do not rise to it, she is much shaken in her seat. Neither is the form of the side-saddle fitted for the trot; and the canter of a well-bitted horse is more safe, because his haunches are more under him in that pace than they can be in the trot. A good, bold, walk, however, with the head in proper place, is essential to a horse that has to carry a woman; and his action should be very true, that is, he should not "dish," or throw, his legs outward, as the term is, in any of his paces, or he will cover the lower garments of his rider with mud when the roads are wet and dirty. To provide against the latter inconvenience, however, all horses intended for this purpose, should not be much under 15½ hands in height, which size corresponds with the lengthened drapery of a lady's riding costume. As a preventive against accidents, ladies' horses, however well broken and bitted, should not be too highly fed; and, if at all above themselves, should be ridden by a careful servant, with good use of his hands, before ladies mount them. It is, however, an acknowledged fact, that horses go more quietly under women than they do under men, which is accounted for by the lightness of their hand, and the backward position of the body in the saddle. We have, in fact, known several instances of horses being very hard pullers with men, standing up in their stirrups, and, consequently, inclining their bodies forward, but going perfectly temperate and at their ease under women.

The power and parts conducive to action in the roadster, or hackney, are derived much from the same shape and make as we have shown to be best fitted for the hunter; but it is desirable that he should be more up in his forehand than the hunter is required to be, as such form gives confidence to the rider. *The most dangerous* form he can

Hackney.

exhibit, if we may be allowed such a term, is, with his fore legs standing too much behind the points of his shoulders, *and those points loaded.* Even with the best-formed hinder legs, the centre of gravity being thrown so far forward beyond the pillars of support, is, in this case, with great difficulty preserved on the horse making a stumble; but with straight hinder legs, a horse so formed in his fore quarters is only fit for harness, where he can recover himself by the assistance of his collar, having no weight on his back. Provided a hackney do not cut his legs, by striking one against the other, which is oftener caused by imperfection in the upper than the lower extremity of the legs, he is not to be rejected because he may turn out his toes a little, some of the very best, fastest, and safest road-horses being so formed. Cutting the hinder legs is a worse failing than cutting the fore ones, as it is a certain sign of weakness; and although we may be told that shoeing will prevent it, we bring to our recollection the old adage, that "a goose always goes like a goose." What is called the "speedy cut" with the fore legs, arises from excess of action, and is a great objection, by reason of the wound given to the leg, which is struck just under the knee. Many good hunters, especially when ridden in hilly countries, such as parts of Surrey, where they traverse the hills on loose and stony ground, are subject to this failing, which is remedied by a boot; and, after all, the danger attributed to speedy cut, in throwing horses down, is much overrated.

The size for a road hackney must be regulated by the size of the person to ride him; but, generally speaking, from 14 to 14½ hands, is the proper height. His strength must also be thus calculated, for a light man does not ride pleasantly on a horse equal to double his weight. But a road hackney should have strength of shoulder, with a round barrel, but not a large carcass, which only wears out his legs. His constitution and feeding can only be proved upon trial; but there are certain indices, such as deep ribs, hardy colour, brown muzzle, &c., which very rarely deceive us. As to the necessity of well-placed hinder legs, it is most clearly shown by the answer given to the following question:—If a horse make a serious blunder forward, and the centre of gravity of his body fall beyond the pillars of support, and is for a moment lost, what restores the equilibrium? Is it merely the chuck under the chin to an animal of his bulk and weight, and that "chuck" given perhaps by the weak, powerless wrist of a feeble old man, or delicate young lady? No: the main effect of the bit, or curb, in this case is, first, warning the horse of his danger; and, next, by the momentary raising of his head, he is better able to bring a hinder leg *instantly* to his assistance, by advancing it under his body, and thus restoring the equilibrium. In the walk, in fact, the horse actually begins to move by advancing the hinder leg under the body, before the fore leg quits the ground; and if he did not do so, there would be no equal support for the body, during the suspension of the fore leg in the air; nor could the body be moved forwards, until the hinder leg had, by quitting its station, taken a new point of support. Seeing then, that in the walk, as in all other paces, the centre of gravity in the horse is maintained, as well as the body propelled, by the action of the hinder legs, the greatest attention should be paid to the position and action of them in the hackney, as the best safeguard against his falling. We should observe, then, when he is exhibited to our view, that, in his walk, the hinder foot oversteps the fore foot, at least a shoe's length, which a horse with straight ill-formed hinder legs cannot do; and if such action be accompanied by generally good hind quarters, it is a great indication of safety, as far as one-half of the body of the horse is concerned. But as the false step is made, not with the hinder, but the fore leg, the chief safeguard against falling is to be found elsewhere, namely, first, in the length of the shoulder, which throws the centre of gravity further back than a short one; and, secondly, proceeding also from the free use of the shoulder, in the act of setting the fore foot down on the ground. It is a general but very mistaken notion, that the safety of a roadster depends upon his lifting his fore feet high from the ground, when he is said to "go well above his ground;" whereas it all depends on the manner in which he places them down upon it. Not only are the highest goers often the most unsafe to ride, for, when they do fall, they fall with a violence proportioned to the height of their action; but, although we do not advocate such extremes, there are thousands of instances of horses going *very near* to the ground, and never making a trip. It is, however, a well established fact, that if the form of a horse's shoulder, and the position of the fore leg, enable him to put his foot to the ground *flat*, with the heel well down, his lifting up his foot high is not at all necessary; whereas, on the other hand, if, by an improper position of the leg, issuing out of a short, upright, ill-formed shoulder, the toe touches the ground first, and, as it were, digs into it; no matter how high such a horse may lift up his leg, in any of his paces, he will always be dangerous to ride. And this will be clearly shown, if we consider the position of the fore leg, when off the ground, or in action. It is bent in the form of a *C*, and the foot suspended in the air, turning inwards, with a curve towards the body. When in this state, were the foot to come in contact with a stone, or any other substance, it would pass over it without resistance, the limb being at that time in a flaccid state; but when it approaches the ground, the limb being extended, and having the whole weight of the fore quarters about to be thrown upon it, if it strike against a stone, or any hard substance, then the case is greatly altered, and a stumble is the inevitable consequence. The base now requires to be firm and even, which it can only be by the foot being placed flat upon the ground. Man, in fact, walks very near the ground, but his toe rarely strikes it. If it did so frequently, he would soon become a cripple, putting falling out of the question. His action proceeds from his hips; that of the horse, as regards the fore legs, from his shoulders; but the principle is the same with each; each is a piece of curiously-wrought mechanism, and according to the correctness of that mechanism is their action true. A wrong notion, however, prevails here, which may lead the purchaser of a hackney astray. It has been asserted by various writers, that if the shoe of a roadster be found worn at the toe, it is a sure sign of his possessing the dangerous action to which we have alluded. This is false; many horses wear at the toe, solely by the act of picking up the foot, and quite independently of placing it down. That many hackneys, however, fall from their shoes being neglected and suffered to wear too much at the toes, we are well aware, as well as from their pressing upon the heels and quarters, from the want of being removed in proper time. When a horse is given to wear at the toe, the wearing part should be steeled.

The best method of ascertaining the manner of putting down the foot, on which we have shown the safety of a hackney depends, is, to ride a horse with a slack rein, on a footpath, on which there are trifling undulations, scarcely perceptible, but sufficient for our purpose. If he walk smoothly over such ground, and do not strike it with his toe, we may be sure he puts his foot properly down, and will not, from that cause, be a tumble-down. But there are various ways in which horses fall on the road; bad shoeing, as we have already said, being one of them, and bad condition another. What is called a false step, very different from a stumble, may occur to any horse, and is occasioned by his accidentally putting his foot on a loose stone, that rolls away from under it, when, of course, his footing is lost. In this case, his chance of recovering himself is in his shoulders being oblique and lengthy (for upright shoulders are always short)

Hackney.

and well placed hinder legs. Thrushes and corns are likewise the cause of stumbling; as likewise is starting, one of the worst failings a hackney can have. In some horses it is a nervous affection, rather difficult to account for in animals of such strength of frame; and often arises from imperfectly formed eyes, such as flatness of the cornea, or outward surface of the eye, generally a small one, causing short-sightedness. In the latter case, this fault in a hackney may be guarded against, by employing a veterinary surgeon to inspect him previous to purchase.

The old adage of "no foot, no horse," applies particularly to the road-horse. The hunter can cross a country upon feet that are very far from good; and by the help of bar-shoes, the coach-horse, with no weight on his back, and with the support the harness gives him, gets pretty comfortably over his stage on unsound feet; but the road-horse must have sound feet. Previously to the use of horse-shoes, the value of a solid hoof was so great as to have been made the image by which the Prophet Isaiah set forth the strength and excellence of the Babylonish cavalry, "whose hoofs," says he, "shall be counted as flints." Both Homer and Virgil mention it as an indispensable requisite in a good horse, the latter making it to resound as it strikes the ground—

> "——— et solido graviter sonat ungula cornu."

We are not going here to enter on a long discussion upon the foot, but only to observe, that the wide hoof and expanded heel of the hunter is not so essential to the road-horse as many persons suppose. Indeed the hoof that has been found to stand *severe* road-work best, is one rather high at the heel, and not very wide, provided the pastern above do not approach too near the perpendicular; forming what is called "an upright pastern," which, by the jar the foot receives from it, when it comes to the ground, is nearly certain to produce disease. The strong foot, however, of which we are speaking, is one that requires care, by being frequently drawn out with the knife, to prevent its becoming too strong; and by giving moderate pressure to the frogs, to prevent the heels getting nearer together than we find them, and they already approximate to contraction in a foot of this description. The just form of the hoof in front, upon which mainly depends its form behind, is said by Clarke to be at an elevation from the ground of 33°;[1] and we are inclined to think, that a much greater elevation than this would approach too near the perpendicular, for any kind of foot. As the inner heel or quarter has more weight thrown upon it than the outer, it is the principal seat of corns and sandcracks, for which reason great care should be taken that an even bearing to the whole of the crust be given by the smith to the foot of the hackney, previously to his setting on the shoe, the inner heel being given to wear away more than the outer on that account.

In the action of the hackney consists his chief merit. It should be smooth, and with not too long a step, or stride, or he will tire. He should also go straight on his legs, as the term is; for although horses that dish their legs may be, and commonly are, safe goers, yet they are disagreeable to ride in wet roads, as they cover the rider with mud. As we have already observed, the action of a hackney should not be high, as that tends to fatigue the rider and destroy himself; and if he puts his foot well down on the ground, he will never fall by reason of his action being low, and he will last the longer for its being low.

The paces of the hackney are in a great measure dependent on the will of his owner. The walk and the canter are most essential to what may be called the pleasure hackney; but for general purposes, the trot is the most useful and available pace in a roadster, and one in which he will continue longer, according to the rate he is going at, than in the canter. There are instances, however—and here is perfection in a hackney—of horses with very oblique shoulders, and excellent hinder legs, being able to carry their riders in a canter, over every variation of road, downhill as well as uphill, without offering to break into a trot, for a great distance of ground; and although not *appearing* to go more than at the rate of nine miles in the hour, are really going twelve. This is the result of the perfection of the points to which we have alluded, and can never be looked for in horses of a contrary make, whose shoulders are short and stiff, and their hinder legs straight. Above all things, what is called "fighting action" in a hackney should be avoided; neither ought the fore leg to be thrown out with a dart, as it is always attended with a dwelling or temporary suspension of the foot previously to its reaching the ground.

Most horses have some peculiarities about them, if not absolute "tricks," as vicious practices in horses are designated. Starting has already been noticed; but plunging is still more dangerous, as in that case a horse seldom stops until he have unseated his rider, at least made many attempts to do so, or thrown himself upon the ground. This latter trick often proceeds, not from sheer vice, but from a sense of pain in the horse, from being too tightly girthed; or from the to him very unpleasant sensation of a cold saddle, with a weight upon it, being pressed to his back; and having once taken a dislike to it, he is very apt to continue it. Against each of these evils it is in our power to provide. Against the first, by not girthing the horse tightly, for the doing of which there is no good reason; and against the second, by having the saddle put on an hour before the horse is wanted, in which time it will become warm, and not disagreeable to the skin of his back, which, in some horses, we know to be extremely susceptible. It is upon this principle that the collars are left day and night upon such road coach-horses as are given to "jib" at starting, the consequence of tender shoulders. But there is one failing to which hackneys are subject, not proceeding from vice, but still attended with danger, as it is often the cause of their falling; and we will endeavour to exhibit this failing. We need scarcely insist upon a good mouth, with neck and head in good place, in the best description of roadhorse; nevertheless, if he will not suffer his rider to avail himself of those advantages, they are useless to him. Such, however, is the case when a hackney, as he is going along in his fast paces, throws his head backwards, which he has always the power to do, his rider being unable to prevent him. Twofold danger attends this fault. First, when in the act of doing it he sees not where he places his feet; secondly, his rider loses his mouth for the moment, and in that moment he may fall. Independently of this, it gives the rider the idea that the horse is becoming fatigued, and doubtless it is an indication to that effect. Our idea, then, of a *perfect* hackney to carry a gentleman is this: A well-bred, short-legged, lengthy horse, with *very good legs and feet*, not under fourteen nor above fifteen hands high, that will walk four miles in the hour, trot eleven or twelve, and, if wanted, will go fifteen in that time in a canter or hand-gallop, *without once throwing up his head*, or requiring to be pulled up. We are, of course, supposing him to be in good condition, and in strong work, or it would not be fair to exact so much from him. But it is only in cases of necessity that any horse should be made to perform the latter task; for we are averse to trespassing unnecessarily upon the powers and capabilities of so noble an animal. On the contrary, we recommend every indulgence that can be granted to him on a journey, and especially in hot weather. At all times, indeed, it is our interest to do so; but, in very hot weather, a few sips of soft water, often given, keep off

Hackney.

---

[1] White says forty-five.

fever, and replenish the loss he sustains by exhaustion from excessive perspiration.

One word more respecting action. We are no advocates for *very fast trotting*. It forces the animal to the very extent of his powers, which, of course, wears him out; it induces his owner either to be constantly displaying these powers in private, or matching him against time in public. Add to this, fast trotting is not a gentlemanlike pace; that is, it has not a gentlemanlike appearance, neither is it agreeable to the rider. This is apparent at first sight, when we follow two horsemen on a road, one on a fast trotter, and the other on a good canterer; although going at the same rate, the cantering horse and his rider are both much more at their ease. With the ancient Romans, indeed, a trotting horse was called a tormentor. Nevertheless, we admit that fast trotting is a proof of action, in excess, but of a peculiar nature, and is, perhaps more than any other, transmitted from sire to son, as the produce of the various Norfolk and American trotters have shown. The amble is a pace very little known in England, although very general on the Continent, where the act of rising in the stirrups by the horseman, in the trot, is not practised. We wonder, however, that horses are not oftener broken to this pace than they are, for the use of women, or of men unequal to fatigue. Although the amble is not allowed to be a pace in the manège—the walk, trot, and gallop being all—it is said to be the first pace of the horse when a foal, but when he has strength to trot, he quits it. Another peculiarity attends it. A horse, we know, can be put from a trot to a gallop without stopping, but he cannot be forced from an amble to a gallop without a halt.

The Pack-Horse.—This description of horse is not now in use. His capabilities were prodigious in carrying weight, but were abused by being trespassed upon. When crossed with the heavy cart-horse, a most useful breed for draught was produced, as also what was called the farmer's hackney, that is, a sturdy animal between the cart-horse and the hackney, useful for all purposes of agriculture, as well as for carrying his owner, and always ready to give help upon a pinch, either in the plough, the harrow, or the harvest-cart.

The Cob.—The word cob is one of new mintage in the sporting world, signifying a powerful, short-legged horse, about fourteen hands high, without any pretensions to blood, but able to carry a great weight, at a certain pace, on the road. He is generally the produce of a light, active cart-mare, and either a thorough-bred or half-bred stallion; and, failing to grow in height, often increases in lateral growth to substance equal to that of the old pack, or miller's horse, of former days. When gifted with action, combined with good shape and appearance, this description of horse is much sought after in London, as also in the country, and often sells for a hundred pounds, to carry heavy elderly gentlemen. The attempt to breed him, however, is a hazardous one, as in case of fault in his action for the saddle, he is not suitable to the coach-horse market, the present rate of travelling requiring more lofty as well as higher bred cattle.

The term *Galloway* now applies to any horse not exceeding 14 hands in height, although it originated with a breed peculiar to the county of Scotland known by that name. In the early days of English racing, there were several capital thorough-bred Galloways in training, at the head of which was the Bald Galloway, sire of Cartouch, and also of the Carlisle Gelding, who, as the *Stud-Book* informs us, "was remarkable for having supported the fatigue of running as a trial horse in private, and with success in public, till the age of eighteen, at which period, after winning a heat near Stilton, in Huntingdonshire (1731), he broke his leg, and died." The celebrated Mixbury Galloway, of the middle of last century, was only 13 hands 2 inches in height.

Previously to the improved system of coaching, and the cheapness and expedition of that mode of travelling, the well-bred galloway was the favourite hackney of jockeys, graziers, horse-dealers, and cattle jobbers, and in fact of all light weights who had occasion to travel long distances on the road in a short space of time; and no description of horse is better adapted to the purpose. Many years since, there was a little entire horse in Devonshire, called Katterfelto, the sire of many most extraordinary galloways, to whose labours on the road, indeed, there appeared scarcely to be any limit.

The Pony.—A horse is called a pony when under the height of 13 hands, 4 inches to the hand. It is difficult to account for this diminutive breed, unless we believe it to have been imported from countries farther north than Great Britain, which appears probable from the fact of ponies being found in greater abundance in Scotland and Wales than in any other part of the island; the effect, no doubt, of climate. In Ireland they are very rare.

There is no animal that improves in form and character so much as the pony does from the effect of good grooming and high keep. A real Welsh mountain pony, in very good condition, especially if not castrated, is a perfect war-horse in miniature, uniting almost every good property his species possesses. As a proof of one essential quality, we can state upon authority, that the Earl of Oxford had a mare pony, got by the Clive Arabian, her dam by the same horse, out of a Welsh mare pony, which could beat any of his racers 4 miles at a feather weight. Whether Welsh, Scotch, or Hampshire (New Forest), ponies have properties belonging to them, which should attract the notice of the hippopathologist, among the most prominent of which are the following:—They are never lame in the feet, nor become roarers. A broken-winded pony is a very rare sight, and they live to the extreme of old age, if not unfairly treated. They are also very little susceptible of disease, in comparison with other horses; and as for their powers of endurance, they stagger belief. A rare instance of the latter excellence may be produced, from the well-known fact of the pony Sir Teddy, only 12 hands high, accompanying the royal mail from London to Exeter, and arriving in that city fifty-nine minutes before it, distance 172 miles, in twenty-three hours and twenty minutes. It may scarcely be necessary to state that he carried no weight, being led between two horses all the way; nevertheless it was a task that we think no full-grown horse would have performed. A correct likeness of this pony was painted by the elder Marshall, of Newmarket. In 1784 a Shetland pony, 11½ hands high, carried a rider, weighing five stones, from Norwich to Yarmouth and back, 44 miles, in three hours and forty-five minutes. As a proof, also, of their powers in crossing a country, the fact may be stated of the late Sir Charles Turner riding a pony 10 miles in forty-seven minutes, and taking thirty leaps in his course, for a wager of 1000 guineas with the late Duke of Queensberry, then Earl March. During the drawing of the Irish lottery, the expresses from Holyhead to London were chiefly conveyed by ponies, at the rate of nearly 20 miles in the hour.

THE CHARGER.

No kind of horse, no animal, indeed, of any sort, makes so prominent a figure in history, sacred or profane, as "the goodly horse of the battle," or war-horse. The description of him by Job is admitted to exceed the powers of human eloquence; "and," as M. Rollin says of it, "every word would bear an explication to display its merits." The *Guardian* (No. 86) has a very ingenious critique upon it;

Charger.

and Bochart devotes seventeen pages to this and all the other passages in Scripture in which the horse is mentioned. Virgil's representation of him, in his third Georgic, is considered as the nearest approach to that of the sacred writer; and the speech, in the tenth *Æneid*, of the hero Mezentius to his favourite charger, when on the point of sallying forth to avenge the death of his son, is not exceeded, in the pathetic, by any other passage in the poem. Homer is blamed for his too frequent allusions to the horse; but the history of all wars produces materials for panegyrics on this noble animal. The far-famed Bucephalus is said to have preserved the life of Alexander, by carrying him out of reach of the enemy, although he had received his mortal wound, and dropped down dead immediately on his (Alexander's) alighting from his back. In the battle which was to decide the fate of Persia, on the ground upon which the great Nineveh once stood, the merit of the victory was chiefly ascribed by the Byzantine historians, not to the military conduct, but to the personal valour of their favourite hero, in which his horse bore his share. "On this memorable day," says the eloquent Gibbon, "Heraclius, on his horse Phallas, surpassed the bravest of his warriors. His lip was pierced with a spear, the steed was wounded in the thigh, but he carried his master safe and victorious through the triple phalanx of the barbarians." How many British soldiers have owed the preservation of their lives to the courage and docility of their horses.

The movement of turning being the most difficult with the horse, by reason of the inflexible nature of his backbone, the one selected for a charger should have great freedom of action, having his hinder legs well bent under his body, so that he may be easily thrown upon his haunches; also much liberty in his shoulders, and pliancy in the muscles of the neck; in which case he will seldom fail in having the proper requisites for his calling. The position of his hinder legs, however, is most particularly insisted upon, because, should they be straight, that is, not inclining inwards from the hock, after the form of the ostrich's leg, he will with great difficulty be made the supple, short-turning, handy animal that he ought to be, to render him perfectly available to his rider, at the head of his regiment, or in the ranks. Perhaps those horses which were destined to mount our ancient nobility, or courteous knights of old, for feats of chivalry, and gained them the palm in that field of romantic honour, were more highly "dressed," as the term is, in the manège, than an officer's charger of these days should be; nevertheless, as Colonel Peters observes, in his *Treatise on Equitation*, London, 1835:—"Although it might spoil a good horse for military purposes to form him perfectly after the higher manège principles, yet he would be equally unfit for that duty if he were left in a raw and ignorant state."

Amongst the ancient Greeks, all horses, as well as all men, were strictly examined before they were admitted into the cavalry; and the precedent cannot be too closely followed. It is well known, that in the various campaigns of the last war, several British officers lost their lives, in consequence of being mounted on chargers not equal to their weight over every description of ground. In one particular instance, a colonel of a light dragoon regiment was cut down in retreating, by reason of his handsome, but powerless charger, being unable to gallop with him over a deeply-ploughed field. At the battle of Waterloo, the ground became excessively wet and soft, owing to continued rain; and, in consequence of it, the Duke of Wellington gave a large price to an officer on his staff for a fine, powerful mare, which had been purchased out of an English fox-hunting stud. In fact, the sort of horse best fitted for an officer's charger, is one which possesses most of the essential qualifications, as well as accomplishments, of a hunter, as his rider, when on service, knows not how soon they may be called for. He should, however, be of airy form, with light action, and well-bred, or he will not look in character with the smart costume of his rider; but to his appearance there must not be sacrificed those essential points, substance and strength, which will enable him to struggle through difficulties, in which a weaker, though more highly-bred, animal might sink. But a trifling deviation in form in the charger, from the points insisted upon in the hunter, may be admitted. For example, the shortness of leg, that is, in the cannon or shank bone, is not exactly desirable in the charger, as his action is required to be of a grander and more showy appearance than we wish to see in the hunter. A moderate length of leg, then, is favourable to such action, and gives lightness, as well as gracefulness, to his movements.

Troop-Horse.

We cannot imagine any brute animal more likely to insure the gratitude of man than the horse which has borne him in safety throughout even a single campaign; and it is not be wondered at its having been made a subject for rebuke to Cato, that he left his charger in Spain, to avoid the expense of bringing him home; or that it should be recorded in praise of Andromache, that she fed the horses of Hector with her own hand. A case parallel with the first, we would not produce if we could; but without having recourse to history beyond the period of our own time, we may set forth a flattering resemblance to the second. The late Duchess of Wellington, during her grace's residence at Strathfieldsaye, in Hampshire, seldom omitted for a day feeding, with her own hands, the favourite charger of her gallant husband.

The height of a charger should not exceed fifteen hands and a half, horses of that size being more easily set upon their haunches, and also made to turn more readily than taller ones. His colour must depend upon circumstances; but next to the silver gray, which best displays his trappings, and which, we may presume, was the colour of the celebrated Phallas (the Greeks called a gray horse φαλιος), bay, black, and chestnut, are the best.

THE TROOP-HORSE.

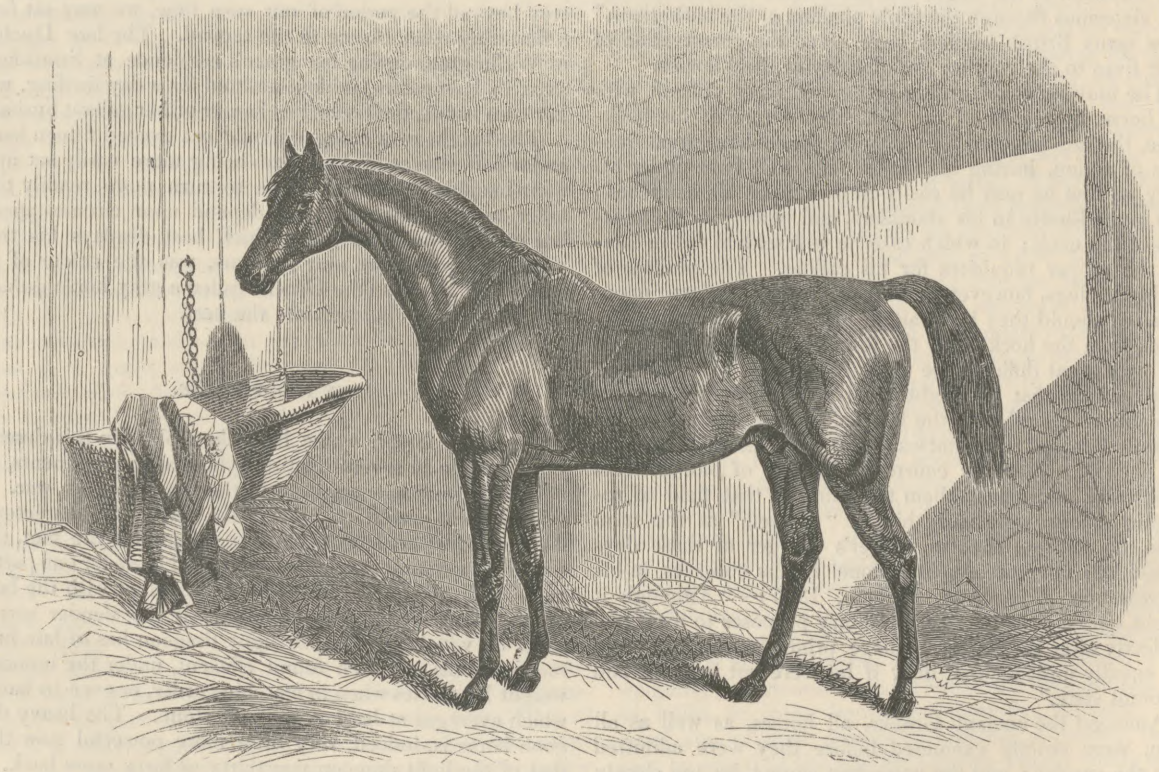
A change for the worse has taken place in this description of horse, in several British light dragoon regiments, the effect of which was apparent in the last European war. It originated in a wish to imitate the style and character of the hussar, without taking into consideration the fact, that that description of cavalry was intended more for out-parties and skirmishing, than for coming in contact with the body of an enemy; and that consequently the slender sort of horse on which the English light dragoon has of late been mounted, has not been found efficient, under the immense weight he carries when in marching order, or even in battle, which averages at least seventeen stone. The heavy dragoon horse is, indeed, very little more powerful now than that of the light dragoon was thirty or forty years back.

The horse best calculated for a light dragoon trooper, is something between the modern coach-horse and the hackney; upon short legs, with good bone, and with much substance in the body. His back should be short, and well ribbed up, his barrel round and large, to allow plenty of room for food, as he is often a long time without it; and hardiness of constitution is a very material point in a soldier's horse. It is true they are purchased when young, many of those for the household troops, at three years old; and their good keep, upon hard food of the best quality, forces them into shape, and makes them what we see them. Most of the troop-horses are picked up at Stourbridge Fair; but the late Sir Walter Gilbert considered that the dragoon guards were never so well mounted as they were in India, when the Cape-bred hackneys were imported for their use. The Duke of Wellington was always very particular about giving them regular exercise, and it is stated by the Druid in the *Post and the Paddock*, that they did 6 miles out of Brussels and back again every morning in two hours; 8 miles of it at a sharp trot, and the other 4 in a walk.

THE COACH-HORSE.

If it cannot be absolutely asserted that the first use of the horse was in harness, it is quite certain that the chariot-horse was held in high estimation in very early times, and is alluded to by poets and historians of all nations and in all languages. Homer says that Diomed, an Asiatic prince, had ten chariots, with a particular sort of horses for each; and he also makes Nestor, at the funeral games of Patroclus, harness the horses for his son with his own hands; and, by his skill in directing him in the race, he wins it. But the Grecian bard goes still further into minutiæ. He even represents Menelaus, on the same occasion, using Œthe, one of the horses of Agamemnon, with one of his own; and Priam is found harnessing his favourite steeds to the car, in which he returns, with the dead body of his father, from Achilles's camp, on the plains of Troy. It would be endless to turn to other writers to show the estimation in which the chariot-horse has been held.

In its present acceptation, the term "coach-horse" includes two varieties; namely, the horse that draws the gentleman's carriage, and the one that is employed in those public conveyances called "stage-coaches." As regards the former animals, we believe a similar alteration has taken place in the form, appearance, and breeding of them, as has been seen in the English hunter within the last half century. The Flanders mares, so highly esteemed, and seen only in the carriages of families of distinction; the well buckled-up, long-tailed blacks and roans—have all disappeared, and we find in their stead the sort of horse nearly approaching to the one which was formerly considered quite well-bred enough for the chase. But the fact is, that nothing but well-bred horses have a chance to stand what is called harness-work on our roads. Those used also for "town-work," as the term is, are of a superior description, amongst which hundreds of good hunters might be selected; but such have been the high prices given for them by the dealers, at an age which would not admit of their being tried in the field, they have found their way into harness, and when once there they remain in it.



The form, however, of what may be termed a splendid town coach-horse, need not be, by any means perfect; and were a judge to examine minutely the points of vast numbers of those handsome horses seen in the carriages in London, or other large towns, he would find them very deficient in several points, essential to any purpose but harness—shoulders and hinder legs especially. But it is fortunate for breeders of horses, that it does not require true symmetry and action to form a grand coach-horse. His false points are, for the most part, concealed by his trappings; and if he be anything near the following form he will make an excellent appearance in harness. His head is not so material, as the bridle covers so much of it; but his neck should rise well out of his shoulders, as the higher he carries his head the better, provided the form of his neck admits of its being drawn inward by the bearing rein, when only moderately tight, in which case he will be easily acted upon by the driving rein. The back of the coach-horse is a material point, as, without an easy slope behind the withers, his forehand will not appear grand, nor will the pad sit well upon him. His hinder quarters should be straight and blood-like; his gaskins well spread; and his tail should be set on high. His action should not be too short for town-work, but the knee should be thrown well up in the trot, to give him a grand appearance. This peculiar action, the result of strong flexor tendons, suited nearly to this purpose only, is observable in colthood, but is increased afterwards by the horse being thrown more upon his haunches by the bit; and the act of drawing is not unfavourable to it. Light work in harness, indeed, is favourable to all action, that of galloping excepted.

The North and East Ridings of Yorkshire may be called the modern Epirus, as the greater part of the London coach-horses are bred there, and get into the dealers' hands at Howden and Northallerton fairs. The most usual cross is between the thorough-bred horse and the Cleveland-bay mare; but the appearance of too many of them incline us to believe that breeders resort, oftener than they should, to the half-bred horse, as well as to the half-bred mare. This, added to the rich grass land they are bred upon, accounts for the coarse, ill-placed shoulders, and flat, fleshy feet that so many of the London coach-horses exhibit. For road-work, in noblemen and gentlemen's carriages, horses cannot be too nearly full blood, provided they have strength equal to their work. Here, as over a country, "it is the pace that kills;" and as, in considerable velocity, the power of a horse is nearly exhausted in moving his own body, he needs every advantage we can give him.

The colour of the gentleman's coach-horse is, for the most part, bay or brown; but by far the most imposing in harness is the silver-gray, with black mane and tail. This colour was held sacred by the ancients; and Camillus is said to have given great offence to the Romans by being drawn through Rome, in his triumph, by four gray horses, no general having before ventured to do so. Gray coach-horses, however (in which Sir Henry Peyton latterly delighted), require the nicest grooming, and the best appointed harness. The piebald look conspicuous, but very few like to drive them. The skewballs are equally unfashionable, although the late Duke of Beaufort, whose taste in these matters was irreproachable, would have nothing else in his carriage. Virgil was partial to the piebald, or party-coloured breed, and mounts young Priam upon one of them in the fifth, and Turnus in the ninth *Æneid*, both Thracian horses.

There are, however, a few points very necessary to be observed in the purchase of the road coach-horse. As in drawing, the force applied proceeds from the fulcrum formed by the hinder feet, well spread gaskins and thighs form a main excellence. His fore legs also should be good to make him a safe wheel-horse, nor can he throw his whole weight into his collar, unless he be sound in his feet. But alas, how many are thus deprived of their natural powers, by being worked upon unsound feet, and expected to exert themselves to the utmost.

There is no truth so easily proved, or so painfully felt by the post-master, at least in his pocket, as that *it is the pace that kills.* A horse at a dead pull, or at the beginning of his pull, is enabled, by the force of his muscles, to throw a certain weight into the collar. If he walk 4 miles in the hour, some part of that muscular energy must be expended in the act of walking; and, consequently, the power of drawing must be proportionally diminished. If he trot 8 miles in the hour, more animal power is expended in the trot, and less remains for the draught; but the draught continues the same, and, to enable him to accomplish his work, he must tax his energies to a degree that is cruel in itself, and that must speedily wear him out.

Let it be supposed, what every horse cannot accomplish, that he shall be able, by fair exertion and without distress, to throw, at a dead pull, a weight into his collar, or exert a force equal to 216 lb.; or, in other words, let him be able to draw a load which requires a force of 216 lb. to move. Let him next walk at the rate of 4 miles in an hour; what force will he then be able to employ? We have taken away some to assist him in walking, and we have left him only 96 lb., being not half of that which he could exert when he began his pull. He shall quicken his pace to 6 miles an hour, more energy must be exerted to carry him over this additional ground. How much has he remaining to apply to the weight behind him? 54 lb. only. We will make the 6 miles an hour 10; for it seems now to be the fashion for the fast coach, and for almost every coach, and every vehicle, to attempt this pace. How stands the account with the poor beast? We have left him a power equal to 32 lb. only to be employed for the purpose of draught.

The load which a horse can draw is about fifteen times greater than the power exerted, supposing the road to be hard and level, and the carriage to run with little friction; and the horse which, at starting, can throw into the collar a weight or force equal to 216 lb., will draw a load of 3200. Let him, however, be urged on at the rate of 10 miles in the hour; deduct the power used in swiftness of pace from the sum total of that which he possesses, and what remains? not a sixth part, not that which is equal to a quarter of a ton, or, if it be a stage-coach, the energy exerted in draught by the four horses will not be equal to a ton.

The coach, and its passengers, and its luggage, weigh more than this, and the whole is still drawn on, and must be so. Whence comes the power? from the overstrained exertion, the injury, the torture, the destruction of the horse. That which is true of the coach-horse, is equally true of every other. Let each reader apply it to his own animal, and act as humanity and interest dictate.

It would be in vain to attempt any standard for road coach-horses. They must be picked up where they can be found, and, if possessed of action, the rest must be left to chance. A good constitution is desirable, for many die in the "seasoning," as it is called, on the road, and a young, green horse cuts a poor figure in a fast coach. Coach-masters are too much given to purchase infirm horses, by which they incur loss, for, if quite sound, it is as much as can be expected that they remain so for any moderate length of time; and we believe the average duration of horses in fast work is not more than four years, if purchased sound. Unsound horses, then, cannot be supposed to last nearly so long, independently of the cruelty of driving them. The most likely horse, however, to stand sound, and do his work well in a fast coach, is one that, with sufficient strength and a good set of limbs, has action sufficiently speedy to admit of his keeping time without going at the top of his pace. When this is the case, he runs his stage, from end to end, within himself, and is as good at the last as he was at the first; but when he cannot *command* the pace, he soon becomes distressed, and is weak at the end of his stage. This accounts for sundry accidents having occurred by wheel-horses being unable to hold back a loaded coach down hill, at the end of the stage, although they would have been more than equal to it at the beginning of it. In fact, many coach-horses are very good for 8 miles, but very bad for 10, so nicely are their powers measured in harness. Above all things, we recommend good legs and feet in working horses, if they are to be had; and an extra price is well laid out in procuring them. Whether they are strong in their harness, in very fast work, cannot be discovered until they are tried; but well bred ones, having substance, are most likely to prove so.

Coach-horses are subject to many accidents, and some diseases nearly peculiar to themselves. Amongst the former is the fracture of a leg, or the coffin-bone of the foot, occasioned generally, it is supposed, by treading on a stone, or any other uneven surface, when the limb is strained in draught. It, however, sometimes happens when the horse is trotting along on very fair ground, and in such cases the accident is rather difficult to account for. In very heavy draught, when the foot is much overcharged with the weight and pressure of the body, a fracture will sometimes take place at the first step the horse takes. Perhaps these accidents may be independent of what is called shape and make, but coach proprietors would do well to purchase their horses with good legs and feet, and then they are less liable to these accidents, and, with good care and good shoeing, may last many years in very quick work.

The diseases peculiar to coach-horses are the megrims and the lick. The former attacks the head, and is caused by irregular motion of the fluids within the vessels of the brain, stopping, for a time, all voluntary motion. The horse in consequence staggers and falls, if not immediately pulled up, and that does not always prevent him. This species of vertigo is generally produced by the effect of a hot sun, especially if the horse be running in the face of it, for which reason horses subject to megrims are generally worked at night. In fact, many coach-horses are good horses by night, although they cannot keep their time by day, in the summer, particularly thick-winded horses. Blind horses also do not like sun, but "as healthy as a blind horse in the winter" is a proverb.

The lick can scarcely be called a disease, but it greatly injures the condition and appearance of coach-horses. When under its influence, they are almost constantly, when not feeding, licking each other's skins, or else the rack or manger. It proceeds from a heated state of the stomach, from the excitement of high food, and almost daily profuse sweating, and is invariably removed by alterative medicines or physic.

A great mistake is made by too many coach-masters in being *under* instead of *over* horsed for their ground. Instead of keeping five horses to work a certain length of ground, and feeding them very high to perform it, it would answer them better to keep six horses on the same allowance of corn that the five horses are eating. The stock would last longer, and the money they cost be "kept together," as the term is, longer, by such means. Each horse would then rest two days out of six, when they were all fit for work, which would keep him very fresh in condition; and there would always be one spare horse left, in case either of the six wanting physic or rest. It is the almost every-day excitement that breaks down the constitution of coach-horses.

THE GIG-HORSE.

Once on a time a country parson and his wife, or a wealthy old farmer, were the only persons seen in England in two-wheeled carriages, then called Whiskies. They were useful though far from ornamental vehicles, having what is termed a "head" to protect the inmates from weather, and, with a very quiet horse, were considered as nearly equal in security to close four-wheeled carriages. In the character and appellations of these carriages, however, a wonderful alteration has taken place within the last fifty years, and even royalty itself has been seen seated in gigs, cabriolets, Stanhopes, and Tillburies; the two last taking their names from the inventors of their peculiar forms. The build of these two-wheeled carriages has reached the very summit of perfection, not only as regards their firmness but their elegance; and it is scarcely necessary to add, that the horses driven in them, as likewise their harness, have equally altered their character. From 200 to 300 guineas (and, in one instance, 700 guineas were paid) have been no uncommon prices given for gig and cabriolet horses; and for gentleman's work we might put 70 as the average of the last forty years.

The choice of a gig-horse (for we confine ourselves to that term for the present) must be regulated by local circumstances. If for London streets, his action should be rather lofty or "grand," as the term is, than fast; that is to say, he should step with his knee much elevated, which of course is unfavourable to speed. His appearance also should be of the first order of his species, not under 15 hands 2 inches in height; and if of a fancy colour, the more money will he fetch in the market. He must be well bitted, carrying his head high, and very quick in getting into his trot, or "upon his legs," as coachmen say, to enable his driver to make his way in crowded streets. We should also add, that this quickness in his motions should be accompanied by perfectly good temper, and freedom from all vice; in which case he is always worth 100 guineas, or more, if in the prime of life and sound.

For the country a different sort of gig-horse is required. In drawing a gig on a soft or newly gravelled road, the resistance is much the same as a continual hill; and therefore a horse with a quick, short step is best calculated for the road, as such action fatigues less than that which we have recommended for London. For all purposes, however, a horse in single harness, to be safe, should be well up before; that is to say, he should go with his fore quarters high up, and not boring on his shoulders. In this case, if he have well-placed shoulders, good legs, and sound feet, free from corns and thrushes; good natural courage to induce him to "run up to his bit," and a good mouth, there will be very little danger of his falling down in a gig; but accidents from vice must depend upon other circumstances. These accidents, however, are often the result not of real vice, or even of ill temper, but of want of knowledge in his owner of putting him properly into his harness, as well as of driving him afterwards.

Innumerable accidents to horses in gigs arise from some part of the harness pinching him, particularly about his withers or back, when he will endeavour to kick himself out of it, to rid himself of the torment. Indeed we have more than once seen a road coach-horse, in regular work, set a-kicking merely from a twisted trace rubbing edgeways against the outside of his thigh.

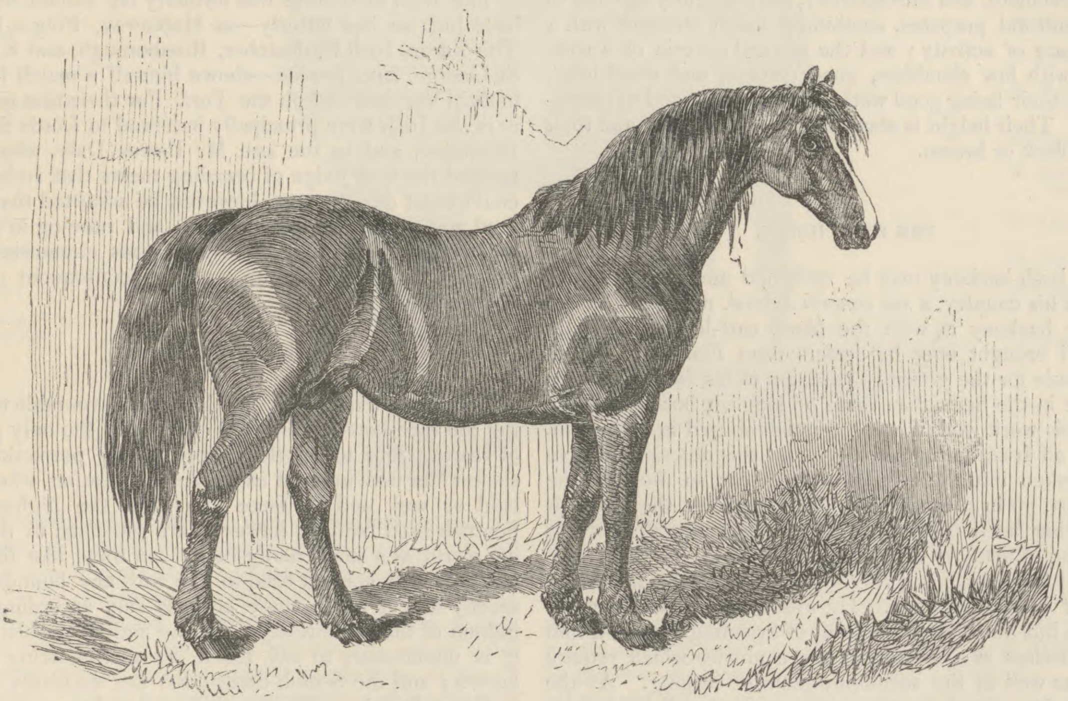
We consider mares objectionable in single harness, for reasons which are obvious; and few of them are to be trusted at certain periods of the year, particularly in the case of a rein getting under the tail. When driven, the precaution of the safety rein should not be omitted. We are also of opinion that numerous accidents from gigs would be prevented, if horses intended for them were to be broken in to them in bridles without winkers, as a great portion of the horses on the Continent are driven. The not knowing what they have behind them is a natural cause of alarm, and would by this means be obviated.

THE POST-HORSE.

This description of horse, although its day is quite gone by, is one of the most useful we have. He is spoken of by Xenophon, in allusion to the posts instituted by the first Cyrus, and as the most expeditious method of travelling by land (*Cyropædia*, lib. viii., p. 496, edit. Hutchinson); although, perhaps, he was chiefly made use of to forward public despatches. Augustus was the first to introduce post-houses, and consequently post-horses and post-chaises, amongst the Romans, disposed at convenient distances (Suet. *in vit. Aug.* vi., 49), but these were chiefly for the purpose of political intelligence. Thus, in a letter from Pliny to Trajan, we find him informing the emperor of his having granted a courier a warrant to make use of the public posts, as he wished him to be quickly in possession of some important facts, communicated to him by the King of Sardinia; and he subsequently (Letter cxxi.) apologizes to his royal master for having ventured, on his own responsibility, to grant an order for his wife to be forwarded by post-chaises, on occasion of a domestic affliction. His letter produced a kind answer from the emperor, approving, *in this peculiar instance*, of the use of the warrants which he had entrusted to his care.

The character and appearance of this class of horses, as well as of all others, has undergone a marked improvement in comparatively modern times. Up to the end of the last century the post-horse was, except in a few instances, an object of commiseration with travellers. With galled sides and sore shoulders, and scarcely a sound limb, he would not go without the lash or spur; whereas he now comes out of his stable in high condition, and runs his 10 miles stage in an hour with a carriage of the average weight, and 12, if required, with a light one. He is also seen to perform either of these tasks without being distressed, unless in immoderately hot weather, when humane persons would check his speed. Montaigne says, "There is a certain general claim of kindness and benevolence which every creature has a right to from man," a sentiment in which we heartily concur; for, although man may be considered as the delegate of heaven over inferior animals, he has no right to go to the very extremity of his authority. It is, however, much to be feared that a thoughtless indifference to the sufferings of the post-horse is too frequently to be laid with truth to travellers in our own country, who, without any sufficient reason, urge him to a rate of speed which cannot be unattended with suffering.

The form of the good post-horse should resemble that of the hunter, which is generally ridden in the deep and close hunting counties of Great Britain; that is, with as much blood as can be got, in conjunction with good bone and strength. The riding horse of the pair must have sound legs and feet; but, if a little the worse for wear, an old hunter makes an excellent hand-horse (if he will not lie down the moment he has to take to his collar at a hill), and innkeepers generally avail themselves of the saving occasioned by putting horses of a less price in that place than the one which carries the driver. Notwithstanding this, the average purchase money of a useful pair of post-horses cannot be estimated at less than from L.50 to L.70.



THE CART-HORSE.

Errors detected by experience are allowed to be equal to demonstration; but this truism is not admitted by a vast majority of English farmers, who persevere in the use of the heavy horse for agricultural purposes, for which, solely, he is by no means fitted, from the slowness of his step (independently of his weight), unless very highly fed. As long, however, as the ponderous vehicles made use of in London and elsewhere for the transmission of heavy goods are persevered in, this equally ponderous animal, which sometimes weighs a ton, may be necessary; but it is certain that lighter horses in lighter vehicles would do the business better, that is, more speedily and at less cost. Notwithstanding the objections to him, the heavy cart-horse pays well for rearing; for, being always saleable at two years old, a certain profit is insured, as for the first year the expense of keeping him is trifling. If on a large scale, and promising to be fit for the London market, or the best-conducted road waggons, he commands a price that leaves a handsome surplus to the breeder.

The chief desiderata in the cart-horse are substance and action. If possessed of the latter, his shoulders and fore-quarters can scarcely be too coarse and heavy; for drawing being an effort of the animal to preserve himself from the tendency which his weight gives him to the centre of gravity when he inclines forward, so the more weighty he is before and the nearer he approximates this centre, the more advantageously will he apply his powers. Notwithstanding this, we are not advocates of heavy horses for farmers' work, much less on the road. The lighter horse gets over in eight hours what would take the heavy one ten; and the great improvement in the present mode of culture, and the implements used for agricultural purposes, do not require more weight or strength than what the Suffolk, Clydesdale, Cleveland-bay, and other lighter breeds, are masters of. Besides, there are periods of the year when despatch of business is of great moment to the farmer, which he cannot command in those mountains of horse-flesh which we see labouring in most of the finest districts in England, tiring themselves by their own weight.

Travellers on the Continent, occupying land in England, should carry in their eye the form and action of the horses which draw the public carriages, particularly those bred in Picardy, in France. The prevailing colour is *iron* roan, and their nature appears to sympathize with that colour; for, Irish Horse.

speaking figuratively, they are as hard as iron itself. It is not unusual to find four or five of them drawing those cumbrous diligences, weighing perhaps 6 or 7 tons, a 20-mile stage at the rate of 6 miles an hour, preserving up their condition to the highest pitch; and this with hay and corn very inferior in quality to that grown in England. To keep up the condition of the English cart-horse, requires him to consume nearly as much as his labour is worth; and unless he lives well he is only half alive, which his sluggish action denotes. In fact, his chief fault lies in his having too great a body and too little spirit, consequently he exhausts himself in the mere act of carrying that body. The nimbleness of the smaller kinds of cart-horses to which we have alluded, is owing to their moderate size; and their immense powers in lifting weight (with the Suffolk Punch, and Clydesdale breeds, in particular) to the same cause, combined with the low position of the shoulder, which occasions weight to be acted upon in a just and horizontal direction. The Welsh cart-horses, especially those in use in the counties of Denbigh, Merioneth, and Montgomery, are eminently adapted to all agricultural purposes, combining much strength with a great share of activity; and the general criteria of a wide breast, with low shoulders, good carcase, and small head, indicate their being good workers, with hardihood of constitution. Their height is about 15 hands 2 inches; and their colour black or brown.

THE IRISH HORSE.

The Irish hackney may be reckoned amongst the indigenæ of his country, a *sui generis* animal, not mixed as the English hackney is, with the black cart-horse, originally and still brought over by dealers from Flanders. He is remarkable for the general soundness of his feet, which are stronger in the heels than those of English horses, and he stands his work well, if not too much abused in his youth. Almost all Irish horses coming under this description have been broken into the plough and the car, so they, for the most part, go in harness; but the worst fault they have is not having been properly broken in, and bitted, which is the cause of many of them being restive.

The Irish hunter is a very different animal from what he was half a century back. He was always celebrated for leaping, but until lately the want of breeding rendered him nearly useless as a hunter, in the countries which require speed, as well as the accomplishment of leaping. At the present time great numbers of excellent well-bred Irish hunters are annually imported into England, and being found to answer well, fetch good prices. This is the result of horse-breeders in Ireland seeing the necessity of putting their hunting mares to thorough-bred stallions, and not, as before, to the slow, *great-jumping* hunter, no matter how low his breed. The improved cross, being again put to the thorough-bred stallion, of course has produced a still better kind of animal, and thus are Irish hunters "progressing" towards perfection.

The method of leaping of the native Irish horse is peculiarly suited to some of our English counties, Cheshire and Lancashire, for example, and likewise to those inclosed with walls both in England and Scotland. To use an expressive Irish phrase, "they have always a leg to spare," implying that they have a ready use of their hinder legs; which is the fact, in tipping or touching walls or banks, with one or both, which gives them a fresh fulcrum, from which they can extend their leap, in case of their finding an unforeseen difficulty or obstacle on the landing side. In the wall counties of Ireland, indeed, the horses are taught to alight on their hinder legs upon the summit of the wall, after the manner of the dog when he leaps a gate, which, if the wall be broad and firm, adds to the facility of the exertion, as also to the safety of the rider. Irish hunters are generally good brook jumpers, being educated, indeed bred, amongst drains; but field gates, or stiles, being of rare occurrence in the pastoral districts of Ireland, they are not to be relied upon as timber leapers, until they have been initiated to that description of fence.

Scotch Horse.

Persons who have had experience in Irish hunters have found them very shy of having a whip, with a thong to it, made use of by the rider, either for the purpose of smacking it, or to strike an unruly hound. This, we fear, proceeds from unnecessary severity in the exercise of the whip in breaking, but which would be obviated if breeders were aware of the inconvenience it occasions to servants, who are called upon to ride Irish horses with hounds in the capacity of huntsmen or whippers-in. We have seen a few of these horses nearly useless from this cause, as servants' horses; although well suited, in every other respect, to this peculiar purpose from their style of fencing and hardiness.

The Irish race-horse was formerly far behind the English; but he has latterly—as Harkaway, Foig-a-Ballagh, The Baron, Irish Birdcatcher, Russborough, and Knight of St George, have proved—shown himself a match for them both in the stud and on the Turf. For their first good runners the Irish were principally indebted to Lords Sligo and Rossmore, and to the late Mr Bowes Daly, who was esteemed the best judge of breeding racers that Ireland ever could boast of. It must, however, be admitted that horses bred and trained in one country, and running in another, meet their rivals under disadvantageous circumstances, in consequence of the loss of condition consequent on a sea voyage.

THE SCOTCH HORSE.

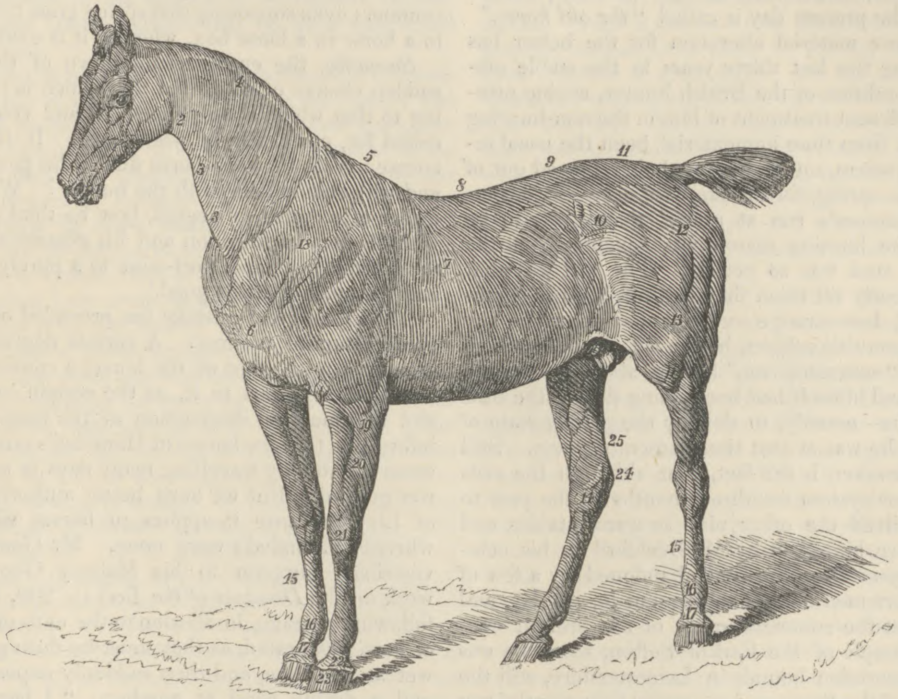
Like all cold countries, Scotland is unfavourable to breeding the race-horse in his best form; and the only prospect of rearing him to anything approaching perfection is to shelter him with unusual care from the weather, when either cold or wet, and to force him with the highest keep. Scottish-bred hunters, however, are esteemed in the hunting world as a stout, hardy race; and they, like the Irish, are now well enough bred to live with any hounds at the speedy rate at which those animals run, according to the fashion of the present day. Of the native Highland pony it is unnecessary to say much, its merits being so well known; and the Scotch cart-horses are decidedly the best in Great Britain. The peculiar variety known as Clydesdale horses stand first in repute. Of the origin of this race various accounts have been given, but none of them so clear or so well authenticated as to merit much notice. They acquired their appellation, not because they are peculiar to Clydesdale, as the same description of horses are bred in the other western counties of Scotland, and over all that tract which lies between the Clyde and the Forth, but because the principal markets at which they are sold—namely, Lanark, Carnwath, Rutherglen, and Glasgow—are situated in that district, where they are also preserved in a state of greater purity than in most other parts. They are rather larger than the Suffolk-punch, and the neck is somewhat longer; their colour is black, brown, or gray; all the essential points for heavy draught are very conspicuously developed; and they are extremely docile withal, and excellent at what is called a dead pull. Mr Charles Philips, of Cracrop, Cumberland, is the best English breeder of them; and some of his two-year-olds, according to *The Druid*, have been sold in Canada at 4 shillings and 8 pence per pound! Some magnificent specimens of this breed are to be seen in the streets of Glasgow, in the service of merchants and carriers. We have reason to believe that, if tried by a dynamometer, the Clydesdale horse would exceed

Treatment of Horses.

any other of his inches and weight in his powers of draught; and his quick step adds much to his value.

GENERAL TREATMENT OF HORSES.

Humanity and mercy are esteemed the choicest characteristics of man; and there is hardly a greater instance of ill-nature, or a more certain token of a cruel disposition, than the abuse of dumb animals, especially of those who contribute to our convenience and pleasure. Judge Hale beautifully expresses himself on this subject in his *Contemplations.* "There is a degree of justice," says he, "due from man to the creatures, as from man to man; and an excessive use of the creatures' labour is an injustice for which he must account. I have therefore always esteemed it a part of my duty to be merciful to my beasts." We know of no remedy for this; but it is pleasing to reflect that in all classes of society so noble, generous, and useful an animal as the horse, is now freed from many evils to which he was formerly subjected. In fact, if the Society for the Suppression of Cruelty to Animals hear of a case, they will send their agent any distance to prosecute it. The short-docking of the cart-horse, the effect of prejudice and ignorance, it being supposed to add strength to his back, is very generally discontinued, and he is allowed the use of a full tail, the only natural defence against the torment of flies in the summer. Those barbarous operations, nicking the tail, and cropping the ears of pleasure horses, are very seldom had recourse to; neither is firing the limbs nearly so frequent a remedy as it was, veterinary science having substituted other equally efficacious, but less painful means. And, though last, not least, the improved condition, and the effect of better stable management, on all horses employed in fast work, has very considerably lessened their sufferings. On this subject we offer the following remarks:—



1. 1. 1. Muzzle, parts about the mouth.
2. Gullet.
3. 3. Windpipe.
4. Crest.
5. Withers.
6. Chest, or counter.
7. 7. Girth.
8. Back.
9. Loins.
10. Hip, or ilium.
11. Croup.
12. Haunch, or quarters.
13. Thigh.
14. Hock.
15. Shank, or cannon.
16. Fetlock.
17. Pastern.
18. Shoulder-bone, or scapula.
19. Elbow.
20. Fore-thigh, or fore-arm.
21. Knee.
22. Coronet.
23. Point of the hock.
24. Ham-string.

Condition, or Stable Management of the Horse.

The improvement in training the race-horse has been the result of two distinct causes, each equally likely to produce the desired effect. First, practical experience, an excellent schoolmaster in such matters; and, secondly, both breeders and trainers of this animal now look into books, not only reading them, but reflecting upon what they read. As we have already observed, trainers dislike green meat, and a racing-colt may now be said to be in training, if not from the day on which he is foaled, from that on which he is weaned; for his condition, at least the foundation of it, is from that period in progress. Again, the early period of his going into work, compared with what it formerly was, but now become so general, has not been without its effect. It has called forth additional exercise of the trainer's professional skill; for it may easily be imagined that bringing very young horses to the post, in the perfect state of condition and full development of muscular power in which we now-a-days see them at every race-meeting in our island, is a very difficult task, and that it is a still more difficult one to preserve them in that state, even for a few days. On the whole, the training system of the present day is not nearly so severe as it was; and railways have done much towards keeping horses in condition, by allowing them to stay at their own stables and training-ground till within a few hours of the race, instead of losing condition by a long walk on the road, and even to say nothing of a fresh stable and fresh water every night. Many of the great favourites have now their own food and water brought to a race-meeting with them for fear of risks, as change of water especially is most detrimental to a horse in form. Both constitution and temper being to be consulted, the very refinement of the art is called for; in fact, the trainer must act upon principle, and very cautiously too, in his efforts to forestal nature. Inasmuch, however, as muscular action produces muscular strength, the racer of the present day, reared as he is reared, and consequently in a more condensed form, does not, with few exceptions, require the very severe work which it was formerly necessary to give him to increase his natural powers, as well as to rid him of the bulk of flesh and humours he acquired in his colthood under the old system of rearing him. A sight of our two-year-olds at the starting-post is the best demonstration of what is here stated. They exhibit a developement of muscle in their forced and early maturity almost equal to that of the adult horse, and carry 8 st. 7 lb. and even upwards, at a racing pace; a weight unheard of upon so young an animal in former times. How far, however, this forced maturity and its consequences—namely, severe work, and the excitement of high keep, at so tender an age—are favourable to him or to his produce in after life is another question; but the use of a system should never be estimated by the abuse of it. If our race-horses are not, and we believe they are not, so stout in their running as formerly—that is to say, twenty years back—the cause may fairly be traced to the great value of produce stakes and others, which bring them to the post at so early an age; so much so, that, in the language of the turf, a four-year-old colt of the present day is called "*the old horse*."

But a still more material alteration for the better has taken place during the last thirty years in the stable management and condition of the British hunter, arising principally from a different treatment of him in the non-hunting months. It had, from time immemorial, been the usual remark of the sportsman, on his hunters being turned out of their stable in the spring, for the *supposed* necessary advantage of the "summer's run at grass," that it was to be lamented that the hunting season was concluded, as the condition of his stud was so perfect. The fact was that until then, or nearly till then, they had not been in condition at all; and, how strange soever it may appear to any one reflecting upon this subject, by the act of turning them to grass for this "summer's run," he was about to undo all that his groom and himself had been doing during the nine preceding months—namely, to destroy the perfect state of condition which he was at that time lamenting over. Still more strange, however, is the fact, that although the evils of this out-of-door system for three months in the year to an animal who lived the other nine in warm stables and well clothed, were hinted at by Mr Beckford in his celebrated *Letters upon Hunting*, and abandoned by a few of our first-rate sportsmen of, and subsequent to, his day, and particularly about the commencement of the present century, by the example of the Earl of Sefton, when he was owner of the Quorndon hounds in Leicestershire, still the ruinous system of the three, and generally four months' run at grass (viz., from 1st of May to the 12th or 20th of August) continued to be practised until these evils were exposed in all their appalling deformity, and the advantages of an opposite system made manifest in a series of letters in the *Old Sporting Magazine*, under the signature of "Nimrod," which have since been published in a separate form, and very widely circulated. We may also add that the effect of this exposure has been nearly a general abandonment of the grazing system in the studs of all men who mean to ride near hounds.

Previously to our enumerating the real advantages of the modern system of "summering the hunter," we will state the imaginary ones of the old one, and which, as may be supposed, are still held to be such by those who reluctantly acquiesce in any kind of reform. First, the purging by spring grass is insisted upon. Secondly, a relaxation of the muscles, and what is called a letting down of the whole system to its natural state. Thirdly, the benefit the feet receive from the dews of the evening, and coming in contact with the cool earth. Fourthly, the saving of expenses. Fifthly, a kind feeling towards the animal, who, they say, is entitled to his liberty for a certain period of the year, also to the free enjoyment of his natural state. And, lastly, the absolute necessity of rest to the limbs, after the labours of the preceding season. We will now make our own comment on each of these presumed facts.

And, first, we admit there is a laxative, and therefore a cooling, property in early spring grass, but as a purgative it is insufficient, which is admitted by the fact of its having been generally considered necessary to give two doses of physic to hunters previously to their being turned abroad for the summer (thus administering the antidote, as it were, before the poison), and to physic them immediately when taken up. Here, then, is at once an answer to the first objection to the improved system of in-door treatment in the summer; even supposing that spring grass could not be given to a horse in a loose box, whereas it is evident that it can.

Secondly, the entire letting down of the system, by a sudden change of food from that which is highly invigorating to that which is only succulent and relaxing, is neither called for, nor can it be wholesome. It is never had recourse to with the race-horse during his period of inactivity, and why should it be with the hunter? We would ask the owner of a horse so treated, how he thinks it would agree with his own constitution and his *digestion*, to be suddenly taken from beef and port-wine to a purely vegetable diet; and the analogy holds good.[1]

Thirdly, a great mistake has prevailed on this point, the preservation of the feet. A certain degree of moisture is beneficial to the foot of the horse, a continued exposure to wet most injurious to it, as the certain cause of thrushes, and in time total destruction of the frogs. Thus, history informs us that the horses in Hannibal's army were rendered unserviceable by travelling many days in succession in very wet ground. But we have better authority here than that of Livy, because it applies to horses which wore shoes, whereas Hannibal's wore none. Mr Goodwin senior, late veterinary surgeon to his Majesty George IV., in his work on the *Diseases of the Feet* (p. 209, 1st edit.), has the following passage, in allusion to the evils of having the feet of horses saturated, as they must be during a summer, with wet at one time, and then suddenly exposed to a hot sun and a drying wind at another. "I have invariably observed," says Mr Goodwin, "where horses are turned out to grass during the dry and hot summer months, that on bringing them up to be put into stable condition, their feet are in a much worse state than they were when they went out, dried up, and so hard and brittle, that, on the application of a tool to bring them into a form to receive a shoe, the horn breaks like a piece of glass, and all the naturally tough and elastic property is lost, so that it requires some months to remove the bad effects. If it is necessary that a horse should be put out of work during the hot and dry weather, I prefer a large box or shed, and soiling with green food; by which means two objects are gained, viz., all the *injurious* effects of a drying wind or a meridian sun on the hoof are avoided, which create such an excessive evaporation of the natural moisture absorbed into the horn from within, that it not only becomes dry, hard, and brittle, but the whole horny box tightens on the sensible parts, and frequently produces great mischief. But in a loose place, moisture may be applied in any desirable way." In addition to the above, Mr Goodwin says, "Horses at grass are much inclined to thrushes;" which renders it unnecessary for us to say more on this subject at present, although we shall by-and-bye offer the result of our own experience in the treatment of horses' feet in the summer.

---

[1] In No. 59, vol. v., p. 645, of the *Veterinarian*, we find the Editor coinciding with Nimrod on this point, in his second review of his Letters on Condition. "These pithy and valuable extracts," says he, "at the same time that they serve to expose our author's views in regard to summering the hunter, demonstrate a sagacity and experience on the subject, no less worthy of the admiration of the professional man, than of the sportsman himself. The leading consideration in summering the hunter is to maintain his condition, or rather, we should say, to guard against his losing that which we know, both by education as medical men, and experience as sportsmen, once lost, will require much time and pains to be re-acquired. Change of food is necessarily productive, in the animal constitution, of alteration of structure; though parts cannot be said to change their nature under their influence, yet they do become greatly altered both in texture and in tone."

Treatment of Horses.

Fourthly, a saving in expense. This is an objection too trifling to be admitted in opposition to any real advantages. It was calculated by Nimrod[1] (allowing only 4s. per week to have been the charge for each horse, supposing him to have been summered at grass), that the extra expense of his six hunters summered after his system, which we shall further explain, amounted to only L.13, 18s. The mere chance in favour of exemption from accidents to which horses abroad are liable, is worth more than this inconsiderable sum to the man who keeps six hunters in his stable; but twice its amount would be realized in the sale of any of the six, if offered at the hammer in November, beyond the sum he would have produced had he been summered solely in the fields.

Fifthly, we would go any length in advocating the extreme of kind treatment to so noble an animal as the horse; but experience has taught us, that neither the open field, nor the shade, is a bed of roses, in the summer months, to the well-bred, and naturally thin-skinned hunter; for the œstrum, or blood-sucker, pursues him in each; and the desperate attempts he often makes to avoid them, shows the horror he has of their attacks. But, unluckily for the advocates of this system, one of the greatest evils of the out-of-door system here stares us in the face. If the horse cannot get away from this host of tormentors, his only remedy against them is, galloping from one end of his pasture to the other, or else stamping with his feet against the hard ground, and often against the roots of trees, to scare them from one part of his body, only to settle upon another. The injury to both feet and legs from a daily succession of these operations, may be left to the imagination of the reader; but against the charge of cruelty, we quote the following remark from *Nimrod's Letters* (p. 268, first edition): "In the very hot weather" (he is speaking of the summer of 1825, which was remarkable for the intenseness of its heat), "I made a few observations, which are not irrelevant to my present purpose, particularly as to the charge of cruelty in keeping hunters in the house in the summer. On the 29th of July, one of the hottest days, the thermometer was one degree higher, at 2 o'clock at noon, in my two four-stall stables, in each of which three horses had stood for sixteen days and nights, than it was in the entrance-hall of my house, which is 23 feet high, and contains three large windows and six doors, and the aspect due east. Now, will any one tell me, that the most tender animal could be injured by breathing such an atmosphere as this? But all is not yet told. I removed the thermometer on the same day, and at the same hour, into the shade, and there it was *four degrees higher than in my two four-stall stables*. Here, then, the objection to horses standing 'sweating in the stables in the summer time,' returns to its real insignificance."

Lastly, upon the subject of rest, and the means of procuring the advantages of it to the hunter by a summer's run in the fields, we cannot do better than quote from the same author. "When discussing the subject," says he (p. 262), "of summering hunters, with a friend who is an advocate for the grazing system, he made use of the following expression: 'I dare say it may be all very well to keep them in the house in the summer, but then they have not the benefit of *the rest* which they get when at grass.' I could not help smiling at this strange perversion of facts; and ventured to ask him, Whether, if he were examined in natural philosophy, and asked, *what is rest*, he would answer, *motion?* and that would not be a whit less absurd. If rest be desirable, as we know it is, for a hunter's legs, after the labours of a winter, surely he must obtain it more effectually in a small confined place, than when suffered to run over a large tract of land, and to stamp the ground with his feet for so many hours each day." Neither does the labour to the legs end here. All persons who have ridden horses whose growth has been forced in their bodies, as that of most hunters has been, must have perceived that, when letting them drink in shallow water, their fore legs totter under them, in the attempt to reach the water with their mouth. Such is the case with the hunter, at least with the properly formed one, when in the act of grazing (for the horse prefers a short bite); and the tremour in his legs shows the stress that is laid upon them, to enable him to reach his food. In fact, many horses (and we could name some well-known hunters) cannot reach the ground at all with their mouths, unless it be by the painful position of placing one fore foot close to their mouth, and the other even with the hinder legs; and consequently their owners have not been able to turn them out, had they been inclined to do so.

It is now our turn to be heard on this important subject to all owners of hunters; and we proceed to state, that the principal objection to summering a horse abroad, consists in the danger we expose him to by the violent change from a stable at the temperature of 63° (the common one of hunting stables), and the addition of warm clothing, to a bed upon the cold ground on a wet night; or, which often happens in the month of May, to the influence of sharp frost; all this, also, when the animal has scarcely any coat on his back to provide against the effects of bad weather; and with a skin highly porous, from long continued friction in the stable. As well might we expect to find animals and plants that can sustain the heat of the torrid, and the cold of the frigid zone, as horses to bear those extremes with impunity! On the contrary, it is the confirmed opinion of most veterinary surgeons, that more hunters have been ruined by becoming roarers, broken-winded, or blind, from this cause, than from any other to which they are subjected; and they are backed in their opinion by reason. For it is not necessary that the newly-turned-out hunter should be exposed to either a wet or a frosty night, to produce disordered functions; the common exhalations from the ground in the evening, are sufficient to produce them, by a sudden constriction of the pores, opened as they have been by the effect of a hot sun during the day. "Heat and cold, moisture and dryness," says Mr Percival, veterinary surgeon to the First Life Guards, and author of the *Anatomy of the Horse*, in his last work on the Horse (p. 64), when treating on the theory of inflammation, "all in their turn become excitants of inflammation; their mischievous agency residing more in the vicissitudes from one state to its opposite, than in any obnoxiousness in our climate, from their excess or continuance. They may operate either directly as excitants, or indirectly, simply as predisposing causes." Few veterinarians, indeed, as Mr Percival expresses himself, now-a-days feel inclined to deny the uncongeniality of cold and wet to the constitutions of horses, or to maintain that they do not very often, in such situations, contract the foundations for disease, which at some future time is apt to break out and prove fatal to them.

[1]

Two tons five hundred-weights of hay, at L.4 per ton	L.9	0	0
Seventy-one bushels of oats, at 4s. 6d. per bushel	14	4	0
Beans	1	10	0
	L.24	14	0
Six horses at grass nine weeks, at 4s. per week	10	16	0
	L.13	18	0

Nor are the remarks of this scientific practitioner and most perspicuous writer, less to our purpose, when speaking of the horse that is turned out of his stable in the winter. "Take a horse," says he, in his chapter on 'Hide-bound' (p. 296), "fat and sleek in condition, out of a warm stable, where he has been well clothed and fed, turn him, during the cold and wet of winter into a straw-yard, and go and look at him three months afterwards, and you will hardly recognise your own horse. You will find him with a long, shaggy, staring coat; a belly double the size it was when in condition; and a skin sticking close and fast to his ribs, which may now be readily counted with the hand, if not with the eye." But here the analogy between the horse turned out to grass in the summer, and the horse sent to a straw-yard in the winter ceases. The latter loses flesh, and becomes hide-bound, both of which will find a remedy in a return to more generous food in the stable, with the assistance of alterative medicine; and he will speedily resume his condition. But it will not be so with the grass-fed hunter. He has accumulated a load of soft, unhealthy flesh, which must be got rid of at the expense of his legs and feet; or, in the language of grooms, "it must be exchanged for better flesh, the produce of hay and corn." By feeding *ad libitum*, however, he has so plethorized his system, and trespassed upon his digestive organs, that this is become not merely a work of labour and time, but one of no small risk to the general soundness of his constitution. Nor is even this the extent of the mischief. Under the most favourable circumstances, it is not in the power of a groom, how good soever he may be, to bring the grass-fed hunter into the field, fit to be ridden, with hounds, until the hunting season is half expired. For proof of this assertion, we need only go to the race-horse, which cannot be made fit to run under at least four months' preparation, although he has not been at grass since he was six months old. Nature will not be put out of her course by violence; and horses can only be got into good condition by degrees, by long-continued slow work at first, increasing in pace as their condition increases; and it has been the attempt to get the grass-fed hunter into something approaching to condition, by hurrying him in his work, under a load of flesh, and with his muscles in a relaxed state, that has ruined thousands of good horses, by the injury done to their legs especially; and will ruin thousands more, if persevered in. The change of food, again, has been the cause of more broken-winded horses than anything else that can be named. "It must dispose," says Mr Percival, "from its being the chief cause of plethora, to general diathesis of the system; and so far it contributes to the production of pneumonia, or any other inflammatory affection." To this we may add blindness, the natural consequence of the dependent posture of the head when feeding, in an animal in the plethoric state that a previously highly-fed hunter must fall into, after being some weeks at grass; and likewise of constant irritation from flies and sun. Neither should the following remark of Mr Percival's be forgotten by gentlemen who turn out their hunters during a wet summer. "Cold," says he, "abstractedly from wet, even although it be alternated with heat, is not found to be near so prejudicial as when moisture is present too; hence we are in the habit of viewing frosty weather as a season of health among horses; and hence it is that the spring and autumnal months are the most unhealthy, the weather being then moist and variable, and the wind generally in a cold quarter." Again, "Two undomesticated horses," says he, "out of three, under five years old, that are taken from cold situations, and kept in warm stables, will receive catarrh. But even domesticated horses that are advanced in years, and that have been accustomed to such changes, do not always escape, unless some precautionary measures be taken; for hunters taken up from grass in August, unless due attention be paid to the temperature of the stable, are often the subjects of catarrhal attacks."

Perhaps the summer of 1835 may be produced in proof of the danger of subjecting stabled horses to atmospherical changes. In the first week of June, 78, 80, 82, and 84 degrees of heat were marked by the thermometer. On the 13th, the maximum of heat was 15 degrees less than that of the preceding day; and on the 23d, the thermometer fell to 47 degrees, succeeded by four days' rain, with wind veering to S.E., back to W., then to N. and N.E., at times furiously high.

We must be allowed two more remarks on the evils of the out-of-door system. Amongst the physical changes which the body is capable of receiving, none is so visibly effected as in the diminished or increased size of the belly; and the latter alternation of form is speedily effected by a horse eating grass, and nothing but grass. When a man goes into training for a match against time, or a prize-fight, the first act of his trainer is, to reduce the size of his belly; for, until that is done, his respiration is not free enough to enable him to make such bodily exertions as are essential to augment his natural vigour, and put him into the best possible condition; and this exactly applies to the grass-fed hunter taken up in August. He has exchanged an active untiring frame for a bloated and breathless carcass; and nothing can be done with him until, by purging and *severe work, when he is not in a fit state to endure it with impunity*, the nature of his frame is altered from weakness to vigorous health. But this must be the work of time, for, although Nature will admit of improvement, she will not allow herself to be hurried by the unreasonable innovations of man.

Our next remarks relate to bodily infirmities and local diseases, to which the horse, by the severity of his labours, is always more or less subject. Several of these, such as splents, spavins, curbs, and ring-bones, are easily checked, if discovered in their incipient state; but when, by being undiscovered for only a short time, a certain progress is made in them, the cure is far from certain, at all events, more difficult. Now, under the old system of the summer's run abroad, this was most frequently the case. Horses, when taken up, were found to have thrown out those excrescences unperceived, which, as soon as they began to work, caused lameness and disappointment; whereas, under the improved system of summering the hunter, they could not have escaped the constant inspection of the groom, and an immediate check would have been given to them. The short-cough, vulgarly and stupidly called a "grass-cough," also too often swelled the catalogue of disasters; and, in six cases out of ten, ended in broken wind or roaring. But it may not here be amiss to address ourselves to owners of hunters, who may adopt either one system or the other of treating them in the summer months; we mean, as regards their legs, the treatment of which now forms a conspicuous feature in the science of the stable, particularly the racing stable. Many valuable animals are ruined in consequence of their owners and their grooms not knowing, perhaps not wishing to know, when their legs are going amiss, and consequently stopping them in their work, before the evil gets a-head. It is irksome, no doubt, to give up the use of a hunter, especially if a favourite one, and in blooming condition; but it is only by such prudent conduct that we can expect a lengthened enjoyment of his services. It is a lamentable fact that, generally speaking, good-constitutioned horses would wear out two sets of legs and feet, which shows the urgent necessity of taking care of them.

We now take our leave of the old, and, we may add, ruinous system of treating hunters in the summer, and proceed to state how, in our opinion (the result of much experience), they ought to be treated in the non-hunting months; as also to offer a few directions for the manage-

Treatment of Horses.

ment of them when in work. To begin, we are far from averse to resting the hunter in the summer, although we cannot shut our eyes to the fact of horses working hard for a great many years in succession, without experiencing what is here meant by "*rest*" (namely, not having a saddle on their backs for three or four months), and remaining sound and healthy to the end of a long life. Our great object is, to give the hunter fair play, by preserving, instead of destroying, his condition at the same time that we rest him; and in this we think, that, by preventing exhaustion in his work when he returns to it, we offer him much more than an equivalent for the fancied enjoyment of his "snuffing the air in his native liberty," and "making his bed on the cool ground," so stoutly insisted upon by many of the old school, who will not march with the times, and who cannot divest themselves of prejudices, how dear soever they may cost them.

The period of "turning *up*," not "*out*," hunters towards the close of the season should depend on circumstances. Those whose legs may be doubtful, should be the first thrown out of work; and after them old ones, who, how well soever they may go over a country when it is soft, are in danger of breaking down when it becomes hard, as it always does in March, particularly in ploughed countries.

The first act of a groom, when his horses have done their work for the season, is to give them two doses of mild physic, which, by their effect on their legs, will greatly assist him in discovering the amount, if any, of the injury that may have been done to them. Should anything serious exhibit itself, we recommend him (unless he be a first-rate professor of his art) to avail himself of the advice of a veterinary surgeon, as to the steps proper to be taken; and the sooner those steps are taken, the better will it be for his horses. The barbarous, the senseless, practice of blistering, generally the two fore legs, and often the hinder ones also, previously to turning out, under the old system, is now, we are glad to say, abandoned, not only on account of its inutility, but, by the spread of veterinary science, sportsmen have found out that the application of blisters to healthy legs is injurious. The merely irritating the surface of the skin cannot be productive of advantage; on the contrary, it often rouses the sleeping lion, which it is afterwards difficult to pacify. As counteractors of internal inflammation, or as counter-irritants, as they are called, blisters are highly useful; likewise to all bony excrescences, such as splents, spavins, or ring-bones, when in an incipient state; but, in order to render them efficacious, they should be repeated till healthy pus is obtained. If judiciously applied in strains, they are also not unserviceable, as they help to unload the vessels near the affected part. Supposing, then, no serious mischief has been done to the legs of a hunter during the season, we thus proceed in our course of treatment of him:—

Prieviously to stripping him of his clothes, he should go through his second dose of physic, and be treated exactly as if he were in work for at least a fortnight afterwards, with the exception of his having only walking exercise, a diminished allowance of corn, and the wisp, without the brush, applied to his body. We now arrive at a point on which there is some difference of opinion, at all events, one which must be left to the option of the owner; namely, whether, as is the practice in the stables of some of our first-rate sportsmen, the hunter is to be kept in gentle work throughout the summer, or to be thrown entirely aside for a certain number of weeks, varying from nine to twelve? We will, however, state the best method of proceeding under each of these systems.

The horse kept in work (we should rather have said exercise) during the summer, should be exercised very early in the morning on soft, but not wet ground (a low meadow, or rather a marshy common, for example), that his feet may have the advantage of moisture, and also that he may not be tormented by flies, or exposed to a hot sun. Two hours will be sufficient, the pace to be varied alternately from the walk to the jog-trot. It is desirable that a horse thus treated should not be tied up in a stall, but have the enjoyment of a large loose-house. Of course, attention should be paid to his feet, removing his shoes every third or fourth week; and they should be stopped with wet tow every second night. To those who object to this in-door treatment of the hunter on the score of danger to his feet, we can only say, from our own experience, that their fears are groundless; and we also refer them to the first cavalry barrack they pass by, or even to the stables of our innkeepers on the road, in which they will find feet in the highest state of preservation, that have been subject to in-door treatment for many years. We prefer damp tow to any other sort of stopping for horses' feet, because, exclusive of the moisture, it affords a uniform pressure to the frog and outer sole of the foot, which is favourable to their healthy state. Indeed, to some of the finely-formed, open feet which we see on first-rate hunters, the soles of which are apt to be thin, this pressure is most advantageous in preventing a disposition in them to become flat or convex, instead of moderately concave; and for this purpose was the "horse-pad," or "elastic stopping," invented by Mr Cherry, veterinary surgeon of London, which may be preferable to the tow, but not always at hand. When the latter is used, it should be forced into the foot with all the strength of a man's fingers or thumb.

The food of hunters thus summered should be regulated by circumstances. Good flesh, we know, is strength; but that which is generated in comparative idleness only contributes to weakness. Our object, then, should be to prevent a horse, treated in the manner we now allude to, from throwing up much flesh, and we must therefore feed accordingly, and also study constitution. At all events, three small feeds of oats (we do not feel ourselves justified in recommending beans—although we know some sportsmen give them—except in very peculiar cases, such as extreme delicacy of constitution, a disposition to scour, or throw off food) per day are sufficient for any horse, with the addition of a large, sloppy, bran mash twice a-week. As to green food, we recommend that with caution. We approve of its being given occasionally for three or four days in succession, merely as soiling, to attenuate the blood, not to produce flesh; and this repeated now and then at intervals, whilst the green meat (be it what it may) is young, but by no means afterwards. Many grooms mix hay with green food, which, after the first two or three times of giving it, we think a judicious plan. But, be it observed, for reasons we have already given, we object to a hunter acquiring a load of flesh in the summer, the produce of succulent food. A moderate use of alteratives is beneficial throughout the summer to horses which live well, but do not work, as, by their mild and gradual impression, a healthy action of the bowels is kept up, as well as insensible perspiration increased.

The horse *not kept in work* should be thus treated in the summer: He should run loose in the bay of a barn, or any large covered place where he gets exercise, and breathes fresh air, without exposure to the sun. His physic, food, &c., should be as before directed; but as he is now unshod, and consequently cannot have his hoofs filled with anything which can impart moisture to them, he should be made to stand two hours every day, under cover, in wetted clay. Unless after firing, or severe blistering, when the sedative powers of cold air are efficacious in checking local inflammation, we prefer the hunter being housed throughout the night, to his lying out even in a paddock, as he is less liable to disease and accidents; but we admit that the danger of exposure to night air is greatly diminished by his having been kept cool throughout the day, by which he is less susceptible of atmospheric influence, or the alternation from warmth to cold, than if his arterial system had been acted upon by exposure to a mid-day sun. The sticklers, then, for the "dews of heaven," and the "bed upon the cool earth," may here indulge their predilections; but, for our own part, we give the preference to the house at night with horses free from disease.

The state of the horses, summered as we have now described, will, in great measure resemble each other, although, as may be supposed, the one which has been kept on in his exercise will be most forward in condition. Neither of them, however, will have lost much of their proper form; but a distinction must be made in our proceedings with them, when preparing them for the forthcoming season. "Suffer a horse to be idle," says Mr Percival (*Hippopathology*, p. 14), "to do little or no work, and feed him well during the time, and the redundant nourishment floating in his blood will be laid up in the form of fat; put the same animal to work, and that blood, which otherwise would have been turned into fat, will now be transformed into materials of strength." Here, then, it is evident that the horse which has been kept in exercise will require somewhat of a different preparation to the one which has remained unshod, and consequently idle. The first will require very little alteration in his proceedings until nearly the approach of the hunting season, as he will soon be prepared for quick work; but it will be by long-continued slow work, increasing in pace as his condition increases, that the second will be quite himself again, from the relaxed state of his muscles, somewhat redundant flesh, as well as his distended belly. In either case, however, there will be no occasion for all that physicking, galloping, and sweating, to get rid of bad, superfluous flesh, that the grass-fed hunter has been subjected to; for if the groom has done his duty by them, neither of these horses will have accumulated much more flesh than we like to see on hunters when they first begin to work, and when that flesh is good. We would have our second horse, the unshod one, taken into his stable early in August; and during the latter end of that month and the next, in addition to his daily exercise, he should, about three times in a fortnight, have a gentle sweat in clothes, which is best effected in a trot, in a large fallow field that has been lately harrowed down, and which is firm, not soft, to the tread.

But we fancy we hear the question asked, Is it not necessary to give physic to all hunters when the summer is past, and previously to their taking the field again in the winter? We answer, *No*. The principal end of physicking hunters is to allay excitement, occasioned by severe work and high keep; and the next, for the benefit of their legs. Thus, for example, as the first-named horse (the one that has been in gentle work throughout the summer), will not sweat so easily as the unshod one, a light dose or two of physic may be serviceable to him during his first preparation for the field, say in August or September, as the means of saving his legs, should he be a strong-constitutioned horse, and have thrown up too much flesh. But there is no absolute necessity for physic at this period to horses that have been properly treated throughout the summer, and not suffered to get foul or fat; and it will be given with more advantage to them after they have been some time at work, or nearer to the commencement of the hunting season, which, after the manner of the racing stable, may be termed a second preparation. We think, however, we cannot do better here than to quote the following passage on this subject from the April No., 1835, of the *New Sporting Magazine* (vol. viii. p. 353), as the ideas exactly correspond with our own.

"To horses summered in the house, physic is now only administered when it is wanted, as is the case with the race-horse; and the groom or his master ought to be able to say *when*. There are many directing symptoms with horses in work, which cannot escape an observant eye; and we do not, as formerly, wait for the swollen leg or the running sore. The barbarous practice, also, of three doses in succession (as was the practice with the grass-fed hunter on being stabled), 'the first to stir up the humours, and the last to carry them off,' with two strong urine balls to wind up, by way of a remedy for consequent debility, is also happily exploded. The strength of the dose is likewise greatly diminished, and consequently all danger is avoided. We take upon ourselves to say, there is no more risk attending administering physic to a horse, than there is in giving him a pailful of cold water, perhaps not so much; that is, provided the drugs are good, and well put together. We, however, strongly recommend all sportsmen and others to obtain physic from the profession, as veterinarians bestow much attention on the making of it up, and obtaining the best aloes, in which there is much difference. The sooner it passes off the better; and this will be much expedited by three loose bran mashes on the day preceding the dose, and exercise previously to its working. Recollect there is no virtue in this case in the aloes, beyond doing its duty in clearing and cleansing the bowels. Calomel, when administered to the horse, should not be hurried, as it is intended to act upon the system, and should therefore be given twelve hours previous to giving the purge. Horses whose bowels are difficult to be moved, should be kept short of hay a day or two before they are physicked, with an additional allowance of bran mashes, and encouraged to drink before they experience nausea."

It may, perhaps, be well to state the "directing symptoms" for administering physic to the hunter, which are thus detailed by Nimrod:—"Among the distinguishing symptoms of foulness in a hunter are these: He appears unwell, without any specific disease: his mouth is hot, his eyes look dull, and sometimes yellow: his coat loses some of its usual gloss, and stares between the hip-bones, and on the poll of the neck: his appetite frequently remains good, but he is more than usually anxious for water: his heels are scurfy, and sometimes crack; he stales often, but a little at a time: his urine is highly-coloured, and his excrements hard, and often covered with a slimy fluid: he is dull when at exercise, and frequently coughs without any appearance of having taken cold: he loses flesh, and looks dry in his skin: his legs and ears are often cold, the latter frequently wet after exercise and sometimes deprived of part of their natural covering: his crest falls; the whole tone of his system appears relaxed; and, without his groom exactly knowing why, he is not the horse he was a week ago." (*Condition of Hunters*, p. 173.) To this we have nothing to add, unless it be to congratulate owners of horses on the terrors of physicking them having vanished with the present improved method of administering the doses; and on the fact, that only a few days' cessation from labour is now required to afford them this relief. We should say, that a hunter is never more fit to go through a sharp run, than on the tenth day after his physic has "set."

But we do not consider that we can close this part of our subject, without a few words on the treatment of the grass-fed hunter, as there are still some who yet abandon him to shift for himself in the summer, and are content to see him return to his stall in August, the very reverse of what he was when he left it in May. Nor is this the worst of it. He cannot be reinstated in the condition in which he was when he went out in May, until hunting is three parts over the the following season. However, we will lay down what we consider the most likely plan to pursue, to fit him for the work he is intended for:—

From the redundancy of blood and humours, and distension of bowels beyond their proper size, which the grass-fed hunter acquires, all violent exertion must be avoided, until such obstructions are removed, which must be the work of time. It is in vain to attempt to hurry a horse in this state into condition, but the first step taken should be to have him clipped, for reasons which we shall presently give. Long-continued slow exercise is the chief agent in hardening his muscles, and strengthening his organs of respiration; but all galloping when in the state in which he will be for the first two months, to get off his flesh, is very highly to be reprobated, as his legs will surely suffer by it, if nothing else does. Two light doses of physic may be useful to him, if he have had none given him at grass; and care should be taken not to use the brush to his coat till the month of November be passed, in case he should not be clipped. Again, veterinary science has informed us, that danger always accrues to horses in the vicissitudes of heat and cold, from one state to its opposite; but more from the latter to the former, as an excitant to general inflammation. Horses taken from grass, then, should be put into very cool stables, and the fewer in one stable the better, for at least the first month. Windows should be left open day and night, merely taking the precaution of coarse matting, or anything else that will stop the entrance of flies; and nothing does that better than matting, frequently saturated with water. Having been clipped, and kept out several hours in the day in slow work (which, by the way, grooms are too often shy of), increasing his pace gradually as his condition progresses, the grass-fed hunter may be brought fit to look at by the first week in November; but he will be at least by a stone a worse horse than he was when he was turned out. We are no friends to quacking in either man or beast; but, knowing that mischief to horses so frequently arises from a long respite from work in the winter, unless some preventive measures are had recourse to, we recommend the repetition of a light dose or two of physic to the grass-fed hunter during frost, or even during open weather, about Christmas.

Having recommended the fashionable operation of clipping to the grass-fed hunter, we will give our reasons for having done so. Nine horses out of ten, treated as he has been treated in the summer, break out into a cold sweat, after work, during the first part of the season, the natural consequence of debility; and the dew on their coat has all the chilling influence of a wet blanket on their body. The removal of the coat by the scissors, then, although it is no remedy for the former, prevents the ill effects of the latter; which, by producing cold on the surface of the body, occasions a determination of blood to the lungs, or other important viscus, and is a great enemy to condition. Although we deny the necessity of clipping a horse that has been *properly* summered (for, admitting that he may have a long coat, he will not in that case break out after work), we allow it the merit of expediting condition, by giving increase of bulk, and promoting the vigour of the horses' renovating powers; and, therefore, in this case useful. Looking at it, however, in another light, we find many objections to it; amongst the greatest of which is the deprivation of the protection of the coat or hair, to an animal so much in want of it as the hunter is, and therefore an outrage on nature. In fact, it is, to a certain degree, a substitute for good grooming, and as such will continue to be in favour with many grooms, as also with such of their masters as submit to be dictated to by them, or who may pay too much regard to appearances.

Having alluded to grooms, a remark or two may not be ill placed. Such of them as have the care of large studs cannot be expected to work, but to overlook those who are under them; and their responsibility is considerable. There is much in the choice of helpers; for none but persons who have narrowly watched it, are aware of the effects of a good dressing to a hunter, not merely in having his skin cleared from impurity, and in improving its elasticity, as well as the tone and colour of the hair, which may be termed the complexion of a horse, but it greatly promotes general health by its effect on the circulation of the blood, as well as all other secretions, and in bad weather is a substitute for exercise.

Good stables are indispensable to the well-doing of hunters, equally so with a comfortable house and a warm bed to those who ride them. Even the veterinary professors have at length acknowledged the benefit of the genial warmth of a stable to horses at work, although, in common with ourselves, they insist on the necessity of well ventilated stables. No doubt it is injurious to any animal to breathe an under-oxygenated air, and the effluvia arising from animal excretions are injurious to eyes and lungs. A hunter should live in a temperature of about 63° of Fahrenheit in the winter, and as much below that point as it can be made in the summer, by means of exclusion of the sun, open doors, &c. But it is essential that a stable in the winter should not only be warm but dry; and if not dry, the ground under and around it should be drained. A delicate horse never arrives at perfection of condition in a damp stable, and it operates powerfully against all others, often being the cause of fever in the feet. Stalls should not be more than six feet wide, nor raised towards the manger; but there should be a slight inclination in the flagging towards the centre of them, to enable the urine to find its way to a drain, which there always ought to be, as it contributes much to cleanliness, and consequently to health. "Loose places," or "boxes," as they are termed, are most desirable for all horses after severe work, and nearly all veterinary surgeons (more especially the late Mr Turner, to whom the public is so much indebted for his illustration of the navicular disease in the foot) have given it as their opinion, that if all horses were suffered to lie loose after work, there would not be half the cases of lameness in the feet that now occur. Desirable as such treatment may be, it is universally impracticable, on account of the space which large studs would occupy; but every sportsman should have boxes about his premises, and his hunters should be invariably put into them for two or three days after work. To their general use there is one objection, although not a serious one. Horses always lying loose are apt to refuse to lie down in stalls, when removed to premises where boxes cannot be had, but they become reconciled to them after a few days. It is, however, the opinion of a celebrated sportsman that if a hunter should have stood his work ten seasons being always tied up, he would have stood it twelve if he had lain loose.

We quote the following extract from Nimrod on *Condition of Hunters*, on the subject of warm stables. After proving, by the fact of the horse degenerating in all cold countries, that warmth is congenial to its existence, he thus proceeds:—"They who attend to such matters will find that the constitution and habit of a horse undergo a change when kept in a warm stable, favourable, no doubt, to the work he has to perform as a hunter in the stable of a hard-riding man. He is not that gross animal which he might otherwise be, if a hard feeder, and kept in a state more nearly approaching to a state of nature. This we may attribute to the increase of insensible perspiration occasioned by increased circulation, whereby the grosser particles of the body fly off and are got rid of. In this state he would bear some comparison with a well-fed English farmer, when put to perform feats of activity with a man of more refined habits of life, where nineteen times out of twenty he would be defeated." Again: "As there is an analogy between a man and a horse in work, let us carry it a little further, and ask, Whether, after a hard day's exercise in the winter, a man would recover sooner if he passed his evening in a warm room, or if he passed it in a bivouac, or

Treatment of Horses.

in a room that was cold and damp." He concludes by giving it as his opinion, that if it be possible to get a horse to look well in a cold stable, it is not in the power of a groom to put him into the height of condition in a damp one; and in this we heartily concur.

We subjoin Nimrod's plan of stabling for six hunters. "I would have," says he, "two four-stalled stables, in which I would keep only six horses, that is, three in each; and I would have a box at the end of each. If possible, I would have a southern aspect, with windows opening from the top or downward, or else on a pivot in the centre, and placed so high in the wall, that, when open, the air may be circulated through the stable, without affecting one horse more than another, and the height of the interior should be only twelve feet in the clear. I would have the stalls paved nearly flat, with only a trifling inclination to the centre; in each of which there should be a small grating over the drain, and the stalls should be no more than six feet wide. There should be at least twelve feet behind the horses, and the exterior walls and doors should be very thick. The wooden partition walls of the boxes should be only 9 feet high, with wooden bolts to the doors; and each box should not exceed 10 feet square. The saddle-room, well fitted up with saddle-cupboards, boiler, &c., should be in the centre of the building; in the front of which there should be a passage, under cover, for horses to stand in when their legs are washed. Of ventilation I say nothing, that being a matter of course; but I would have the sides of the stalls 9 feet high at the head, with small iron racks, and pillar-reins for each horse to be dressed in. I should be very particular about the stall-posts, for these are frequently the cause of severe injury. When I went to see the king's stables at the palace at Pimlico, I was astonished to see almost every other horse in them with capped hocks. On inspecting the stall-posts, I perceived the cause. They were of fluted stone, and with angles, which proved that Mr Nash (the architect) knows nothing about the inside of stables. Stall-posts should be made of wood, quite smooth and circular; and they should extend to the ceiling, or be at least ten feet high."

Paddocks.—Some persons turn their hunters into the fields in the summer, because they have no small paddocks, or any outlets to their buildings, and are averse to their horses remaining all the year round in the house. Nothing, however, is easier than making temporary paddocks, or outlets that will restrain stallions, or any horse that may be put into them, without the chance of their breaking out of them. Let a small space, say 30 or 40 yards, be hurdled around, and the hurdles lined with faggots reared up from seven to eight feet high. The faggots will be all the better for the exposure to the air during a summer; and as horses cannot see through a fence of this sort, they will never attempt to break through it.

Food.—The proper feeding of hunters has much to do with their condition, and likewise with their remaining sound. Food should be proportioned to work, and it should also be of the very best quality. Hay that has been much heated in the stack is above all things to be avoided, as, from its powerful diuretic properties, it debilitates, and creates thirst; and mow-burnt or heated oats are equally productive of mischief. Eight or ten pounds of hay per day are as much as any hunter should eat, and that which is produced on dry upland ground is best. Indeed, we are far from thinking that rich meadow hay, finely scented as it is, and apparently so full of nourishment, is fitted for any description of horse that is required to go fast, and we are quite certain that thousands of horses are destroyed annually by the effects of hay and water. The latter cannot be too soft, and when not so, it should be kept in the stable some days previous to use, and with a small portion of bran in it. Mr Percival (*Hippopathology*, p. 25) mentions forty-nine horses being killed in one stud, in France, by a disease produced by eating bad hay and oats.

But nothing puts the groom's knowledge of the art of feeding hunters more to the test than the management of such as are either naturally thick-winded, or afflicted with chronic cough; and as in man the digestive organs are oftener than any other disordered, so the respiratory organs in the horse are the most common seat of disease. It is, however, in the power of a groom, by great attention to feeding, keeping the habit of body from becoming foul and plethoric, and well regulated work, to make horses of this description tolerably fit to go with hounds; whereas in bad hands they would be nearly useless, at all events dangerous to ride. Such horses are generally hearty feeders, and when so, should have a setting muzzle, as used with race-horses, put on them on the night before hunting, unless they have been out with hounds within three days. Water also should be sparingly given to them on that day, and not after three o'clock P.M. Frequent mild aperients, or alterative medicines, are very efficacious here; for, as in the human subject the lungs often become the seat of disease as a second cause of indigestion, the state of the digestive organs should be minutely attended to with horses of this description.

A broken-winded horse is never seen in a stud of hunters; but Nimrod's remark on this subject is in accordance with what we have now written upon it. "Most veterinary surgeons," he says, "attribute this disease to the consequences of high keep. Here, no doubt, they are in a great measure correct; but if good grooming were not for the most part a match for the effect of high keep, what would be the fate of our race-horses, which eat almost as much corn as they can swallow from the first month of their existence? Amongst them a broken-winded horse is a rarity."

Many nostrums are prescribed for thick-winded horses—amongst them, carrots in the winter, and green meat in the summer. We approve of a few carrots in the winter, but object to green meat, unless in small quantities. Is not flatulency the distinctive feature of a disordered respiration? And what promotes that equally with loading and distending the stomach with green food? The small dimensions of a horse's stomach evidently show what nature intended him for, namely, *to go fast;* and the pathologist would very soon convince us that, in proportion as that organ is distended, will the respiratory organs be oppressed. Hence the indispensable practice of not allowing hunters their usual allowance of food and water on the morning of hunting; as also of putting the setting muzzle on the racer the night before he runs. The food most proper for all horses, but particularly for such as are not perfect in their wind, is that which contains most nourishment in the smallest compass or space.

But we must not overlook the treatment of the *sound* hunter before and after hunting; as we consider the lives of more than half of those hunters which have been lost from the effects of severe chases, to have been lost from want of knowledge of how they should have been treated, at either the one or the other of these periods. Nimrod, in his letters on this subject, doubts whether it be in the power of hounds to maintain a chase long enough to cause the death of a horse, fairly ridden with them, provided that horse have been properly treated in the summer, and is in what is called strong work, or quite fit to go, on the day of the run. Without stopping to argue this point, which is not capable of proof, we will proceed to show in what state a hunter ought to be taken into the field, to meet fox-hounds, giving him fair play; and the man who takes him there when not fit to go, must always be prepared for the consequences.

We consider a hunter, in proper condition, equal to at

Treatment of Horses.

least three days' hunting in a fortnight, taking the average of sport, which will, of course, at some certain periods, send him oftener into the field in one given time than in another, as, after a severe day, he should have a week's clear rest. But since the second-horse fashion has been so general, it is impossible to speculate on this point, as it so often happens that one of the two horses the sportsman sends to cover, returns home without having done much. The chief point, however, to be insisted upon is, that the hunter should have a good gallop, causing him to sweat freely, on the day before he goes to hounds, and if for half a mile on rising ground, it will be more favourable to his wind. His food on that day should also be attended to, in reference to his constitutional peculiarities; for, if not the best winded horse in the stud, or given to throw off his meat on his road to cover, he should have no water after three o'clock the preceding afternoon, with the exception of a few swallows to make him relish his corn, on the morning of hunting. Sending hunters out now with full bellies has no excuse; whereas one was found for it, when they left their stables five hours sooner in the morning than they do at present, and returned to them often five hours later. We allude to past days in which there were few artificially made covers, and when foxes were found by the "drag," through long chains of woods, and certainly ran over much more ground than modern foxes do, which, being generally bred near game preserves, run shorter, and are not so stout as formerly.

After Hunting.—The treatment of a horse now will depend on what he has been doing. If not a severe day, no further notice of him is requisite than to ascertain whether he feeds as usual; and if not, an alterative ball,[1] with a liberal allowance of tepid water, will soon restore his appetite, by allaying the over-excitement that has checked it. It is after a severe day's work that danger to a hunter is to be apprehended, the consequence of over-excitement of the vascular system, and he should be in this case narrowly watched. If merely fatigued, such are the restorative powers of the animal, rest, in a large loose box, with an hour's exercise daily in the open air, will soon bring him about; but we should be on the alert against fever. Here, however, we generally have notice,—some directing symptoms which cannot be mistaken, such as hurried respiration, extreme thirst, restlessness in his stall, a considerable relaxation of the muscles in the interstices of the hips, reddened eyelids, and a quick pulse. But unfortunately for hard-riding sportsmen, it too often happens, that such is the rapidity with which what is termed accidental inflammation takes place in the horse, that the most prompt measures will not always arrest its progress, and the most common termination of it here is in the feet. Not only does the animal suffer great pain, but should he not cast his hoofs entirely (the fore feet are most commonly affected), he becomes what is called pomice-footed, and of no value afterwards as a hunter. Knowing this to be the case, we are advocates for some prophylactic measures to be taken after a very hard day; something repellant and sedative administered, which may not only prevent an inflammatory attack, but, by cooling the system, and consequently restoring the appetite, enable the horse to go sooner into the field again, than if he had been entirely abandoned to his own restorative powers.

But the most critical period with the over-ridden hunter is when he first appears to show distress, which he often does on his road home, or even before he quits the field; and here mistakes have been made, which have caused the death of many a good animal. In the first place, his rider fancies it necessary to drag him home, perhaps many miles on a cold winter's evening, to "his own comfortable stall," than which, just at this time, a large and cold stable, and the first he could be put into, would be far more beneficial to him. Again, he says, "I'll not do any thing to him till I get him home, when I will have him bled;" whereas, since all horses that die from exertion beyond the limits of vital power, die from suffocation, it will then be, in all probability, too late, as *instant* relief is wanted. A stimulating cordial is likewise at this time good (a pint of sherry as good as any other), but both are bad if inflammation has commenced; also keeping up a strong determination of blood to the surface by friction of the body, head, and legs, with warm clothing afterwards on the body and head; a well littered down stall, with plenty of fresh air. A gallon of blood should be at first drawn; and if the increased action of the heart and arteries continues, the horse should be well blistered behind the elbows, and lose another gallon of blood. Blood-letting from the foot veins is also highly to be recommended in cases of extreme exhaustion, after a hard day with hounds. It is a very simple operation, and can never do harm; but we advise it to be performed by a veterinary surgeon.

They who have never before experienced it, may be alarmed by an inward noise in a distressed horse, which may be mistaken for a beating of the heart, whereas it proceeds from a convulsive motion of the abdominal muscles, or muscles of the belly. It is, however, a symptom of deep distress, and is only relieved by relief given to the lungs, by bleeding and other preventive means.

Treatment of Horses' Legs.—We have already said that the management of horses' legs forms part of the science of the stable, and a most important part too. It is no where so well understood as in racing stables; but from the violent nature of his work, the hunter is equally indebted to it. The barbarous practice of blistering all four legs previously to turning out is now happily exploded; but as in less violent exertion than following hounds, a certain insecurity from accidents is inseparable from the delicacy of all animal structure, the legs of hunters will occasionally fall amiss. It being useless, however, without stating the extent of the injury, to talk of prescribing remedies, we have only to state, that a very efficient one has been found for the torturing one of firing, in many cases where the actual cautery was considered as the only one. For example, for ligamentary enlargements, cases of enlarged joints, tendons showing symptoms of giving way, or any other appearance in the limbs, of a departure from their primitive tone and vigour. This consists in the application, during the non-hunting months, or any other period of rest, of the mercurial charge, in either of the following forms. It consists of the common mercurial *plaster* (not *ointment*) of the shops, made up according to the London Pharmacopœia; and in the proportion of half a pound to a leg, applied in a warm and consequently liquefied state, and when covered by deer's hair, bound to the limb by means of a linen roller. At the end of a fortnight, the stitches of the bandage being decayed, the charge will slough off, when another, if necessary, is put on. It is to the highly absorbent property of mercury that the benefit here derived is to be ascribed; and it is no small recommendation to it that, in addition to the general restoration of the limb, the painful operation of the actual cautery, as also the blemish occasioned by it, are avoided. Major's remedy has also of late years very much superseded firing, and has been applied with great success to the Reiver, Scythian, and several other capital race-horses. It requires, however, to be applied by a very skilful hand, as it has played sad havoc with hair and hoofs, where the operator has not understood his business.

---

[1] The following alterative and sedative medicines are found efficacious at this time:—Cinnabar of antimony, 3 oz.; balsam of sulphur, 2 oz.; camphor, 1 oz.; nitre, 4 oz. To be made into ten balls; one ball a doze. These are known among grooms by the term "red balls."

It is, however, a well known fact, that hunters will work and stand sound, for many successive seasons, with legs apparently much out of form. Enlargements take place in the sheath of tendons after strains; also from blows, where the parts become lined by a thick coat of lymph; and sometimes the body of the bone itself is found thickened, from a deposition of bony lamina over the original bone. When all this has been in progress, we question the propriety of any active measures, unless, as is generally the case, a feeling of soreness is expressed after work, by a shifting, or favouring of the limb or limbs in the stall; or by a "feeling" manner of going on first quitting the stable. When legs are really callous, little impression can be made upon them, unless by active measures; but physic, rest, and good grooming, are the best preservatives of these most essential members of the horse's frame; with the friendly auxiliaries of hot-water, flannel bandages, and loose boxes, after severe work, and good shoeing at all times.

The Foot.—Owners of valuable horses may congratulate themselves on the assurance that, by the aid and extended influence of veterinary science, they have no longer to apprehend injury to the feet from the mere application of shoes. On the contrary, they may rest satisfied that, provided no internal disease attack them, from over-excitement by work (and that often is created on ground where shoes would be unnecessary, such as crossing a very deep country), they will be not only as sound and healthy, but *in better form*, from having been properly shod, than if they had not been shod at all. Some hoofs, however, having a greater disposition to secrete horn than others, and thus called strong feet, should never remain more than three weeks without being subject to the drawing knife of the blacksmith (the ruinous butteris is now put aside), and the shoes properly replaced. Neither should stopping with damp tow be omitted; as moisture, *not wet*, is beneficial to the health of the foot. Here then, again, are at once apparent the evils of the out-of-door summering of hunters. The foot of a horse so exposed, is at one time saturated with wet, and at another exposed to a drying wind and a burning sun, the contractile powers of which upon horn are too well known to require comment. Do what we may, however, horses that are required to "go the pace" will always be more or less subject to diseased feet, quite unconnected with shoeing; and against such diseases there are but two precautions on which much reliance can be placed:—First, let hunters be well prepared for their work, and properly treated after it; and, secondly, let them have sufficient obliquity of pastern-joint (in our opinion one of the most important points in the whole structure of the horse), to break the force of concussion; which, together with over-excitement of the vascular system, is the parent of that irremediable disease of the navicular bone, formerly called "founder;" and by the wiseacres of old times, "chest-founder," because the muscles in that part wasted, from the inability of the suffering animal to exert them. The posture of a horse in his stall, when afflicted with this complaint, or fever in the feet, is too characteristic to be mistaken.

We have only one more remark on shoeing. In following hounds across deep countries, hunters are apt to strike a hinder foot against a fore foot, and inflict a severe wound. There have, indeed, been many instances of the total separation of the back sinew by this, often unavoidable act, particularly in leaping brooks. It was formerly very generally believed, that the blow was inflicted with the *toe* of the hinder shoe, to obviate which, shoeing smiths were ordered, by hunting grooms, to let part of the hoof protrude over the front of the shoe, but still the evil continued. It was, however, asserted, in the letters of Nimrod, that it was by the *inside edge, or the rim of the hinder shoe*, and not by the toe, that the act of over-reaching was performed. This was at first doubted, but experience has confirmed the assertion; and we have reason to believe, there has not been an instance of serious mischief by *cutting*, from an over-reach, since the inside edge, or rim, has been rounded off, or bevelled. Indeed, a moment's reflection would dispel all doubts on the subject; for the obtuse form of the toe of a horse-shoe could not inflict the severe wounds we have seen inflicted (often cutting off part of the fore-heel); whereas the inside rim of a worn shoe is nearly as sharp as an ordinary knife. Besides, the act is performed *after* the hinder foot has overstepped the fore foot, and therefore cannot be performed by the toe, but in the act of drawing the hinder foot back, after it has overstridden its bounds. Bruises from over-reaches still occur, which, though sometimes serious, are comparatively, with cutting, harmless, as fomentation and a few days' rest will effect a cure.

The action of the hinder leg reminds us of one useful hint to grooms travelling hunters on the road. If we follow a well-formed horse, with the free use of his limbs, on a road upon which his footsteps are imprinted, we shall find the hinder foot oversteps the fore foot in the *walk*, but falls behind it in the slow *trot*. Exclusive of relief to the muscles by change of action then, it is safer to vary the pace from a walk to a slow trot on a journey, as causing less fatigue to the hock-joint, by which curbs and spavins are frequently thrown out. Add to this, the slow trot is the safest pace a horse goes, because his step is shortest. (C. A.) (W. H. L—Y.)

HORSEMANSHIP.

As to the question, Who was the *first* horseman? it would be in vain to inquire, for even the writers of ancient fables do not agree upon the point. By some it is pretended that Bellerophon first mounted a horse; that Pelethronius first bridled him; that he was harnessed by Erichthonius, and fought upon by the Centaurs of Thessaly. But quitting fiction, we learn from the Sacred Writings, that to Egypt we are indebted for the equestrian art, from which country, by the aid of the colonists who emigrated from it and from Phœnicia, it was introduced into Greece (perhaps by Erichthonius, fourth king of Attica), where it attained to great perfection. Although there was no cavalry employed in the Trojan War, equestrianism must have been much practised and well understood in Homer's time, which is at once proved by a reference to his works. In the fifth book of the *Odyssey*, the shipwrecked Ulysses, tossed by the waves on a plank, is compared to a skilful horseman on an unruly steed; and in the fifteenth *Iliad*, we find one man managing four horses at once, leaping from the back of one to another, at their full speed. Herodotus (in *Thalia*) speaks of hunting on horseback in the time of Darius, even descending to the particulars of an accident in the field to the noble satrap of Persia; and likewise the same writer (in *Melpomene*) mentions the Amazonian women hunting with their husbands on horseback. Xenophon also says that Cyrus did so, when he exercised himself and his horses. Again, with reference to those early times, we should not pass over the introduction of horses and horsemanship into the public games of Greece, and particularly the Olympic Games, which, according to an expression of Pindar, as far transcended all the others as gold is superior to the baser metals.

From the same authority we learn, that the Ethiopians and inhabitants of India, as cavalry, formed part of the expedition of Xerxes against the Greeks. But it appears that the Arabs and the Parthians, who afterwards became so famous for their equestrian accomplishments, were ignorant of the art at the period in question; at least both these nations fought under Xerxes, the former on camels, and the latter on foot. The Persians were more celebrated for their horses than for their riding. According to Athenæus, they were more solicitous of their ease and safety, than anxious for reputation of boldness and dexterity in horsemanship. The Scythians and the Sarmatians were both famous about this period, as well for their breed of horses as for their skill in riding them. In fact, so renowned were the former people, that, according to Gibbon, they were supposed by strangers to perform the ordinary duties of civil life on horseback; "to eat, to drink, and even sleep, without dismounting from their steeds."

The people of Mauritania, Numidia, Massilia, Nasamonia, and other adjacent parts, are also spoken of as having possessed breeds of excellent horses, but were still more distinguished for their singular mode of managing them (on the authority of Livy, and Cæsar) without the aid of a bridle, and even in battle by means of a small switch or wand, turning them to the left by striking on the right side of the head, and *vice versa;* and stopping them by striking the front of the face. These practices are also confirmed by Ausonius, who celebrates the Emperor Gratian as having excelled in them. All we have to remark here is, that we are glad such practices are abolished, not only on our own account, but for the sake of horses, who must have been greatly tortured before they were brought to such a state of obedience as to be ridden *infrœni* (without bridles), as Virgil says of the Numidians, and this in the confusion and excitement of a battle. There is an elegant passage on this subject in Lucan's *Pharsalia,* descriptive of the several tributary nations which Juba took into the field in the cause of Pompey, against Curio's army, which he entirely defeated.

> "Autololes, Numidæque vagi, semperque paratus
> Inculto Gætulus equo," &c.

Thus translated by Rowe:—

> "With him unnumber'd nations march along,
> Th' Autololæ, with wild Numidian throng;
> The rough Gætulian, with his ruder steed;
> The Moor, resembling India's swarthy breed;
> Poor Nasamons, and Garamantines join'd;
> With swift Marmaridans, that match the wind;
> The Marax, bred the trembling dart to throw,
> Sure as the shaft that leaves the Parthian bow;
> With these Massilia's nimble horsemen ride;
> They nor the bit, nor curbing rein provide,
> But with light rods the well-taught coursers guide.
> From lonely cots the Lybian hunters came,
> Who, still unarm'd, invade the salvage game,
> And with spread mantles tawny lions tame."

The Greeks transmitted the art of horsemanship to the Romans, who soon equalled, if they did not excel, their instructors; and nearly one of the first public acts of their first king was to establish the equestrian order, the second order in Rome; the *equites,* or horsemen, being placed far above the commonalty, and next to those of the highest quality and fortune in the state. In short, were proof wanting that horsemanship, as an accomplishment, was held in the greatest esteem in the early ages of the world, it would be found in the fact of the accomplished Cicero (*De Off.* lib. 2, c. 13) telling his son Marcus, with the vanity that now and then breaks forth in the splendid effusions of that great man's pen, that the eyes of the world were upon him, on account of his father's fame; and that he had received the praise of the whole army for his excellence in *riding.* But the exercise and art of horsemanship occupied much of the study and attention of the Roman youth; and we find Horace inviting them to the practice of it, in the eighth ode of the first book.

Descending from the heroic ages, in which the earliest history we possess informs us the art of horsemanship was in full force and vigour, to comparatively modern times, the first notice we find in our own history of the art of riding horses, is in the tilts and tournaments; the earliest mention of which we find in the French historian Nithard, who reports, that, at an interview which took place at Strasburg between Charles the Bald and his brother Lewis of Germany, the followers of both these princes fought on horseback; and, by way of marking the period, it may be observed, that Charles the Bald succeeded to the throne of France A.D. 840. Ducange affirms, that these combats were for some time peculiar to France, and expressly called French combats, *conflictus Gallici.* Scarcely anything distinct, however, is known about them till we find them practised in England, about the year 1140, in the reign of Stephen, after which time they became general all over Europe, particularly in England, where they were displayed on all great occasions. The spots most famous for them in London, were the Tilt-Yard, near St James's Park, and Smithfield; which the neighbourhood of the latter place confirms, by the names of the streets, such as "Giltspur," "Knight-rider," and so on. They are also known to have been practised on the spots now called Cheapside, Barbican, and Bridewell; and to have been exhibited in considerable splendour in various parts of the country besides, which a reference to Sir Walter Scott's romance of *Ivanhoe* will show. These were the days when "to witch the world with noble horsemanship" was one of the chief accomplishments of a gentleman; in which the management of the horse and the lance was amongst the principal requisites of knighthood; when the contest, both in real and in mimic war, was decided by the superiority of such means; the days of chivalry, in fact, which, as a well-known historian says of it, in his portrait of the character of a perfect knight, the accomplished Tancred, "inspired the generous sentiments and social offices of man, far better than the base philosophy, or the baser religion of the times."

Not only is good horsemanship well suited to the pith and nerve of the English character, but it has always been considered as one of the corporeal accomplishments of a gentleman. Thus Clarendon, in his character of the Duke of Newcastle of his day, says of him, that "he was a very fine gentleman, active, and full of courage, and most accomplished in those qualities of *horsemanship,* dancing, and fencing, which accompany a good breeding; in which his delight was." But there are other than mere personal advantages attending good horsemanship. It is the habitual contempt of danger that ennobles the profession of the soldier; and horsemanship, as practised in England at present, and with the *esprit de corps* of the several hunts, tends much to the same end. Those who pursue it in the field, learn to expose themselves to danger with less reluctance, are less anxious to get out of it, or given to lose their presence of mind when in it, than persons whose pursuits have been of a different turn; in fact, it may be said to increase natural courage. It was with this view, that the late Duke of Wellington always gave every facility to officers who wished to hunt or ride steeple-chases. Such persons, again, as merely ride on horseback for exercise, find in it the great preservative of health. Nay, more than this, persons of tender constitutions have surmounted the weakness of their nature entirely, by horse-exercise and hunting; in proof of which, many cases could be quoted. The following, of a patient of the celebrated Dr Sydenham, is perhaps as conclusive as any other:—A gentleman, a relation of the Doctor's, who was brought so low by consumption, that there appeared to be no possibility of a recovery by medicine, was induced by him to try horse-exercise, and a journey to his native country. On leaving London, he was so weak as to be lifted on his horse, and was refused admittance to the first inn he stopped at, being supposed to be in a dying state. Notwithstanding, he persisted in riding, by easy stages, to Exeter, and gained so much strength by the way, that though one day his horse lay down with him, in some water, and he was forced to pass many hours in his wet clothes, he not only sustained no harm by the accident, but arrived at Exeter greatly recovered. Thinking he had gained his point, he left off horse-exercise, and had a relapse; but, on betaking himself again to the saddle, he obtained a perfect recovery. Nimrod, in one of his hunting tours, says,—"My time was almost divided between my saddle and my bed; but I never knew what it was to be fatigued when I lived temperately, and went early to rest. Indeed, such a life bade defiance to disease. A celebrated physician of the last century used to recommend riding on horseback to his patients. 'Live,' said he, 'in a saddle.' That riding is the most wholesome of all exercises, I have little doubt. Despite of all the vile stuff that finds its road down his throat, who ever heard of a bilious post-boy?" To this might be added, the no small advantage a person mounted on horseback derives from breathing a purer air than when on foot, and consequently nearer to the ground. The salutary effect of the motion of a horse, also, on a sluggish or diseased liver, is acknowledged by all medical men.

We shall now take a view of horsemanship in the only forms in which it is at present applied to any useful or pleasurable purposes; namely, military, hunting, racing, and on the road, leaving the art of instructing horses for the circus to those who find it profitable to fit them for it, which we admit they do to very great perfection, though we fear not without the necessary privation and punishment unavoidable, we believe, in such kind of instruction; or, in other words, in making animals perform far more, we conceive, than the Creator of them ever intended they should perform.

The military seat approaches nearer than any other to that of the manège; and, by reason of the horse-soldier having, in general, but one hand to hold his bridle with, is one which gives him great command over his horse, without disturbing his seat. He sits well down in his saddle, on his fork, or twist, with his body erect, and in perfect equilibrium with his horse; his legs well stretched down the sides, with a firm pressure of the calves, as well as of the knees and thighs, and the feet firm in the stirrups. But it is not by any *one* of these aids that he becomes a good horseman. He must be in perfect unison, as it were, with his horse's actions and paces, to maintain a good and graceful seat; and, in proportion to the just balance of his body, will he be able to have a steady hand, a point of vast importance to the dragoon. The importance of this balance, and keeping himself in a proper equilibrium with his horse, is increased by the fact of his not being allowed to rise to the horse's trot, and therefore requiring a still finer use of the bridle hand. "The man who rides with the aid of the proper equilibrium," says Colonel Peters, "will, in case of necessity, know when to apply the strength he has retained with a steady, light hand, and govern every motion according as he finds it necessary for his purpose; play light with his own weight upon the saddle (by a gentle spring in the instep of both feet on the stirrups), with an easy pressure of both thighs, knees, and calves of the legs. When the horse jumps or plunges, then these aids are also requisite to keep the seat; but, in an easy, steady pace *forward*, it is most particularly to be pointed out to a young man, and cannot be too often repeated, that, to become an easy, elegant, or proper horseman, he must learn to ride with comfort and pleasure to his horse as well as to himself; he must learn to seek his balance from his hip upwards, to keep the body with a slight inclination backwards from the perpendicular, and balance himself thus gradually on his horse in all the different paces; which, of course, cannot be expected all at once. A man that rides by the force of his knees alone, shaking his arms and hands, although he rides his distance in the same period of time that the good rider would, yet he cannot be said to ride his horse, or to have any part of his body in the proper equilibrium; but the man who rides his horse with a light, steady hand, and elastic body (which, when disturbed even, has the power of restoring itself to its former seat), in unison with the horse's action, may be truly said to ride in the proper equilibrium."

The act of mounting may be called the first step in practical horsemanship. With horses perfectly quiet, it matters little in what manner we approach them; but in every thing that relates to horses, a certain precaution is necessary. Let the person who is about to mount, then, walk up to his horse, not directly in his face, lest he may alarm him, nor behind him, lest he may strike at him, which he would thus give him an opportunity of doing. Let him rather approach him on the left side, over against his shoulder, inclining something more to his head than to his flank. In the summer time, when the flies are troublesome, this caution is not ill bestowed, because the quietest horses will sometimes strike out, sidewards, after the manner of cows, to rid themselves of their tormentors; and many a man has been injured in the abdomen, or thigh, from this cause. Old writers on horsemanship recommend the horseman, when about to place himself in the saddle, after having put the left foot firmly into the stirrup, to take the reins and the pummel of the saddle in his left hand, and laying his right hand fast upon the hinder part of the saddle, thus to spring into his seat. We should prefer his taking a lock of the mane, together with the reins, into the left hand; because, if he be a man of any considerable weight, his having recourse to the saddle for all the assistance he may require, would be very likely to displace it, especially as no horse in the hands of a good horseman is now tightly girthed.

When he is mounted, the proper adjustment of his reins is the next thing to be attended to. If a single-rein bridle, he has nothing to do but to draw the reins with his right hand through his left, till he finds he has got hold of his horse's mouth equally on both sides of it, when he shuts the left hand, letting the little finger separate the two reins. The same should be done with a double-rein bridle, only observing, as they are drawn through the hand, that the horse's mouth is to be consulted, as to whether that attached to the bridoon or to the bit is the one required to be first acted upon. Many an inexperienced horseman has met with accidents from want of a proper discrimination as to the right use of the reins, when mounted on high-spirited horses, with finely made, that is to say, highly susceptible, mouths, and unused to a rough hand. The bridle reins should be held at a convenient length; for, if short, they will discompose the attitude of the body, by pulling the left shoulder forward; and they should be held with a firm grasp, dividing them, as before mentioned, with the little finger. When a horse pulls at his rider, he should advance his arm a little, but not the shoulder, towards the horse's head, raising his hand towards his breast, and the lower part of the palm rather than the upper; but he should not shorten the rein in his hand if he can command his horse without it, or he may lose the proper *appui*, or bearing of his mouth. Old writers recommend the bridle-hand to be held perpendicular, the thumb being uppermost, and placed on the bridle. Modern practice is in favour of the knuckles being uppermost. The perpendicular hand may do very well in the school, or with the severe bit of the highly-drilled dragoon horse; but no man could ride a free-going race-horse over a course, or a hasty hunter over a country, in that form.

In dismounting a horse, the bridle and mane should be held together in the left hand, in the same manner as in mounting. Unless the horseman be very active, he may put his right hand on the pommel of the saddle to raise himself, previously to throwing his right leg back over the horse; when, by grasping the hinder part of the saddle with the right hand, he lets himself down with ease. The right leg, however, should not be bent at the knee, or the spur may strike the horse's side, in the act of being thrown backward.

The Seat.—It was well observed by Don Quixote, in one of his lectures to Sancho, that the seat on a horse makes some people look like gentlemen, and others like grooms. But a wonderful improvement has taken place within the last half century in the seat on horseback, of all descriptions of persons, and effected chiefly by the simple act of giving the rider a few more inches of stirrup-leather. No gentleman now, and very few servants, are to be seen with short stirrups, and consequently a bent knee, which, independently of its unsightliness, causes uneasiness to the horse as well as to his rider; whose knees being lifted above the skirts of the saddle, deprive him of the assistance of the clip, by his thighs and legs. The short stirrup-leather, however, was adopted with the idea of its giving relief to the horse, although a moment's consideration would have proved the contrary, and for this reason; the point of union between a man and his horse, as well as the centre of action, lies just behind the shoulder-blades, which, as must be apparent to every one, is the strongest part of the horse's body, and where the sack of wheat or flour is placed by the farmer or the miller. With short stirrup-leathers, the seat of the rider is thrown further back on the saddle, instead of being exactly in the centre of it, and consequently his weight thrown upon the part approaching the loins, the weakest part of the body, and very easily injured. From the same mistaken notion was the saddle formerly placed nearly a hand's-breadth from the shoulders, which, of course, added to the mischief; but modern practice has entirely remedied this, as it is now placed as near as possible to the shoulder-bones, so as not to interfere with the action of them.

Next to the advantages of a good seat to the horse, stands the ease and elegance of it in the rider. In the first place, what is natural is easy, and there must be no formal stiffness of the body of a man, or of a woman, who wishes to look well on horseback. When we see a man sitting as upright as if he were impaled, and his body not appearing to yield at all to the motion of his horse, we cannot fancy his having a good hand upon him, because he cannot be in unison with him in his action; neither can he be firm in his seat. But to some persons a good seat is denied by their shape and make. For example, a man with short legs with large calves, and very round thighs, cannot sit so close to his saddle as another whose legs are thinner and longer, and of course yield him a firmer clip; and whose thighs, instead of being round, are hollowed out on the inside, as we see in the form of our most eminent jockeys. The seat of the short-legged, large calved, round thighed man, has been jocularly termed the "wash-ball seat," and not inaptly neither, for, like a wash-ball in a basin, he is seldom at rest in his saddle, from the absence of a proper clip. The thighs, in fact, are a most essential part of the horseman in giving him a good, graceful, and strong seat, as on the form of them depends greatly a good or bad position of the knee, which is a point of the utmost importance, not only to the eye, but to the firmness of his seat. The thighs, in fact, should be applied to the saddle and to the sides of the horse, chiefly by their inner surfaces, or the knees and toes would be too much out; and although the line is by no means required to be perpendicular, yet the shoulder, the hip, the knee, and the foot, should not deviate too far from it, to render a seat perfect. When this is the case, we may be certain the disposition of the thighs and legs is correct, as they will hang down sufficiently straight, and without force or restraint; which can never be the case, unless the body of the rider is placed evenly on the saddle, opening his knees a little, whereby his fork will come lower in the saddle, giving him the appearance, as Shakspeare expresses it, of being "incorpsed and deminatured with the brave beast."

The position of the foot of the horseman is material both to comfort, safety, and elegance. In the old style of riding, the heels were turned outwards, which, of course, threw the toes inwards, and very near to, as well as parallel with, the shoulders of the horse; but this is all wrong. The toes should be turned a little outward and upward, which the slight opening of the knee induces. No animal, human or brute, can look well, or exert its strength well, with toes turned in; and the position is contrary to everything approaching to elegance.

The position of the foot in the stirrup, however, varies with the pursuits of the horseman. The soldier always, the rider for pleasure, or on the road, generally, rests on the ball of the foot, with a gentle play of the instep. But the man who rides after hounds, and the jockey when he rides a race, find it necessary to have the foot more home in the stirrup, with the toes turned a little upward, as well as a little outward. The advantages of all this are twofold. First, it gives them more power over their horses, by furnishing them with a more substantial fulcrum; and, secondly, to the man following hounds, it is a great security against the foot being chucked out of the stirrup, by the seat being disturbed in a leap, or from any of those causes which perpetually occur in crossing a country.

Great as has been the alteration for the better in the seat of Englishmen, in general, by increasing the length of the stirrup-leathers, and thereby placing them more properly in the saddle; yet, in the schools of the military this system has been said to have been carried too far, so as to endanger the safety of the rider. Indeed both Hippocrates and Galen speak of a disease which, in their time, was occasioned by long and frequent riding with the legs hanging down without any support, stirrups then not being in use. How it happened that an advantage so obvious was so long in being made available, is not for us here to inquire; but we consider the support of the stirrup to be the *sine qua non* of the management and services of the saddle horse, for all essential purposes. Nevertheless its most essential use is confined to Great Britain alone, and that is, in enabling the horseman to rise in his saddle to meet the action of the horse in his trot, by which means a pace, otherwise most disagreeable and fatiguing, is rendered nearly the pleasantest of any. So long as the demi-pique saddle was in use, in which the horseman was so deep-seated and trussed up as to make falling almost impossible; and he rode, as Sir Walter Scott made King James to ride, "a horse keeping his haunches under him, and seldom, even on the most animating occasions of the chase, stretching forward beyond the managed pace of the academy;" pressure on the stirrup might have been dispensed with, but with the saddles of the present day, and the more natural action of the horse, we consider it quite indispensable. It is indeed to the disuse of this practice in France, and other parts of the Continent, where rising in the stirrups is never resorted to even on the hardest trotting horses, that is to be attributed the almost rare occurrence of persons riding any distance, or at a quick rate, for pleasure. To this peculiar system in our horsemanship also are we indebted for our rapid style of posting, as without it post-boys could not endure the fatigue the action of a horse creates, especially in hot weather, over a fifteen miles' stage, at the rate of ten or twelve miles an hour, without a moment's intermission;

whereas, by means of it, he performs that task with comparative ease and comfort. The objection to it on the part of foreigners lies in the fancied inelegance, if not indecency, of the motion, which we consider not worthy of an argument; but of this we are certain, that what is called "riding hard," that is, *not* rising in the stirrups in the trot, nor leaning any weight upon them in the gallop or canter, must be extremely distressing to horses, and especially to such as carry high weights.

Previously to our describing the various kinds of seat, it is necessary to observe, that how well soever a man may be placed upon his horse, his performance upon him will mainly depend on the use he makes of his hands. It is on this account that old writers on horsemanship have dwelt upon the difficulty of the art, rendered more so, in their time, when the airs of the manège formed part of it. The fact, however, is notorious, that not more than one man in a hundred of those who have been riding horses all their lives, has what is called "a good hand upon his horse," much less a fine one, which falls to the lot of but few. When, however, we consider, first, that the hand of the rider is to the horse what the helm is to the ship, that it guides his motions and directs his course; and, secondly, that we have recourse to a severe and cutting instrument, acting upon so sensible and totally unprotected a part, as the *natural* mouth of a horse must be,—it is at once apparent, that not only a fine hand, with an easy bit, must be most agreeable, and, at the same time, most serviceable to the horse, in anything he is called on to perform, but that it constitutes the very essence of fine horsemanship. It has been before observed, that a horse's ear has been figuratively said to lie in his mouth, and no doubt he receives the instruction from his rider chiefly through that medium. How material, then, is it that it should be conveyed to him in a manner in which he is not only most likely to understand it, but in one the least disposed to irritate him? How often have we seen a horse fractious and unpleasant both to his rider and himself, when ridden by an indifferent horseman (allowing him even a good seat), but going placidly and pleasantly when mounted by another with a low and fine hand, which appears to sympathize with all his motions, and all his wishes. It is here that Art becomes the handmaid of Nature; and it is the assistance which it is in the power of a jockey with a fine hand to give a horse, which alone exhibits the superiority of one horse over another *in himself* equally good.

Whence this superiority of hand arises, it is very difficult to determine, particularly as it is so frequently apparent in men possessing equally good seats on their horses. From the well-known fact, that it is an accomplishment which in thousands and ten thousands of cases never can be acquired by the practice and experience of a long life, we may almost consider it to be, like the poets, an *ex re natâ* property in the human composition, and thus sought for in vain by those to whom nature has denied it. That it is intimately connected with the nervous influence of the touch is obvious, from its being the result of the action of the hand and arm; and it is in being delicately alive to every motion of the horse, that the excellence of a good hand consists.

Seat on the Road.—Of the various and too often fatal accidents that occur to horsemen, the majority occur on the road. The reason of this is obvious. They are generally, with the exception of cases of inebriation, the result of horses running away with their riders, and either coming in contact with something in their course, which suddenly stops their career, when either one or both are thrown headlong to the ground. Accidents of this description are very frequently attended with the most serious consequences, and show the necessity of persons who get on horseback being capable of commanding their horse. Next come accidents from horses falling, which are often attended with fracture of limbs, if not loss of life, chiefly, perhaps, from the hard nature of the ground on which the horse and his rider are thrown; for, if a twentieth part of the falls sportsmen get in the field, their horses so frequently falling upon them, were to occur upon hard ground, the danger in hunting would put a stop to it. Falls from horses starting only happen to persons who have a loose seat, and such should ride none but horses free from that fault. But the greatest safeguard on the road, next to a firm seat, is derived from the hand of the rider, who should never trust himself entirely to his horse, however safe he may consider him. He may tread on a rolling stone; the ground may give way from under him; he may step into a hole; or, by the effect of sudden alarm, he may lose the centre of gravity, and then, in all or either of these cases, the fall is worse, by reason of his getting no assistance from the rider, which he may have looked for, until past recovery, when he comes to the ground with a crash. We therefore recommend persons who ride the road, always to feel their horses' mouths lightly, by which means not only will the proper equilibrium be sustained, and they will be carried better for it; for, observe, a horse with a weight upon his back, and one without a weight upon his back, are by no means in relative positions, but, should a false step be made, the aid of the rider being *instantly* at hand, is nearly certain to recover him. By which rein the mouth should be felt, supposing the bridle to consist of a bit and a bridoon, must depend on the sensibility of it, although by changing the pressure from one to the other, the mouth is kept fresher and more lively than when one only is used, and especially if that one should be the bit. There is a certain, but not a large, proportion of horses, that are rideable for all purposes on the snaffle only, whose mouths are generally kept fresh by the light pressure they receive. These are perfect mouths; but, nevertheless, horses that have them in this perfection should not be left quite to themselves in any one pace.

Previously to the general use of coaches and railways, road-riding was much more in use than it is at present; and immense distances were travelled over in a day by graziers, horse and cattle dealers, racing jockeys, and others, whose habits of being so much on horseback rendered them superior to fatigue. A hundred miles, from sunrise to sunset, on the same horse, was no uncommon day's work, and this when the roads were in a very different condition from that in which they now are, abounding in ruts and quarters, so that horses were travelling over half their ground, either on a narrow ridge, between two ruts, or over loose unbroken stones; and these were the days in which really good roadsters fetched large prices, as only horses with very good legs and feet could stand fast work long, or be depended upon as to safety. But all modern feats of men on horseback, or indeed the feats of any other period, on the authenticity of which we can rely, retire into the shade before that performed, November 5th, 1831, by George Osbaldeston, Esq. of Hummanby Hall, Yorkshire, over Newmarket Heath, who rode 200 miles in 8 hours and 42 minutes, winning his herculean match with 1 hour and 18 minutes in hand. As may be supposed, he was not restricted to the number of horses, which consisted of twenty-nine, then in training on the heath; but he rode one of them, Mr Gully's Tranby, by Blacklock, 16 miles, at four 4-mile heats. Mr Osbaldeston, also celebrated for his bold and judicious riding to hounds, appeared very little fatigued; and, after the use of the warm bath, and a short repose, joined in the festivities of the evening, and did not retire to rest till an hour after midnight.

An easy seat in the saddle is very important to persons who ride many hours in succession on the road. To accomplish this the following rules should be observed:—To sit well down in the middle of the saddle, with just that length of stirrup leathers that will allow of the fork clearing the pummel of the saddle; for a greater length than this would add to the fatigue of a journey, and lessen the rider's command over the horse. On the other hand, short stirrup leathers create fatigue by contracting the knees, and thereby adding to the exertion of rising to the action of the horse in the trot, which should chiefly proceed from a gentle play of the instep. The body of the rider should incline forwards in the trot, as, by forming a proper counterpoise, the movement of the horse is facilitated; and, above all things, steadiness of seat is required, or the latter will be much incommoded in his action. So distressing, indeed, is a swaggering unsteady seat, that it is a well established, though not a universally known fact, that horses will carry some persons of considerably greater weight than others, long distances on the road, or over a country in hunting, with less fatigue to themselves, solely because they ride them with a firm seat and an easy hand. In a long day's journey on the road, great relief is given to a horse by now and then dismounting from his back, and leading him a few hundred yards; as also by frequent sips of water, particularly if the weather be hot. As to *frequent* baiting of a hackney in a day's journey, the practice is not recommended. In a journey of 60 miles, he should only be stopped once, but then it should be for at least 2 hours, during 1 hour of which time he should be shut up in a plentifully littered stall. It is well known that a horse in good condition would perform this distance without hurting him, if he were not baited at all, but we are far from recommending the practice. Short stops, however, on the road are injurious rather than beneficial, and teach horses to hang towards every public-house they pass by, in their journey.

Most horses should be ridden in double-reined bridles long distances on the road, and all should be ridden with spurs. Should they flag, or become leg-weary towards the end of a day, the use of the curb may be the means of avoiding falls; and, by the gentle application of the spur, a sort of false, that is, more than natural, action is created, which will have the same beneficial effect. As to the rate at which horses should be put on the road, that is a point so much under the control of circumstances, that no line can be drawn respecting it; but our experience assures us, that if a horse has to perform the distance we have already taken as a fair day's work, namely, 60 miles, under not a very heavy man, he would perform it with more ease to himself, and feel less from it the following day, if he travelled at the rate of 7 or 8 miles in the hour, than less. In the first place, this rate of speed is no great exertion to a horse of good action, and also in good condition; and in the next, by performing his day's work in less time than if he travelled slower, he gets sooner to rest, and is, of course, sooner fit to go to work again. Let it, however, be observed, that he should have 2 hours quiet rest in the middle of the journey, which will enable him to perform it without fatigue. But we do not recommend this rate of travelling, when a much greater extent of ground is before us. If a horse is to be ridden 200 or 300 miles or more, he ought not to travel, in the best of weather, more than from 30 to 40 miles per day, and he should rest the entire of the fifth day, or he will become leg-weary, hit his legs, or perhaps fall. We are of course alluding to valuable horses, with which extra expense is not to be put into the scale against the risk of injuring them. The earlier travelling horses, in the summer particularly, start in the morning, the better, that they may get their day's journey over in good time, and be early shut up for the night.

The following good advice to persons riding on the road is very much to the purpose, and may be quoted here:—"When you ride a journey, be not so attentive to your horse's nice carriage of himself, as to your encouragement of him, and keeping him in good humour. Raise his head; but if he flags, you may indulge him with bearing a little more upon the bit than you would suffer in an airing. If a horse is lame, tender-footed, or tired, he naturally hangs on his bridle. On a journey, therefore, his mouth will depend greatly on the goodness of his feet. Be very careful, then, about his feet, and not let a farrier spoil them." To this we add, that, as has been already observed, horses often fall on the road, from the state of their shoes being neglected; in journeys, and on hot and dusty roads especially, the feet as well as the shoes demand care. They should be stopped every night with moist clay, or cow-dung, or what is better, wetted tow, which, whilst it cools and moistens the foot, acts beneficially, by causing pressure to the sensible sole and the frog.

The Hunting Seat.—Next to that of a jockey, on whose skill in the saddle thousands of pounds may be depending, the seat of the fox-hunter is most essential of any connected with amusement. He must not only be firm in his saddle, to secure himself against falls when his horse is in the act of leaping, but he must unite with a firm and steady seat a light and delicate hand, to enable him to make the most of his horse, as well as to preserve himself as much as possible against danger. His position in the saddle should resemble that which we have recommended for the road, with the exception of the length of his stirrup leathers, and the position of his foot in the stirrup irons. The former, the length of stirrup leather, should depend on the form and action of his horse, as well as the nature of the country he has to ride over. With a horse very well up in his forehand, with his haunches well under him, and going perfectly collected and within himself, his stirrup leathers may be long enough to admit of the knee being very nearly straight, and the foot resting on the ball. But, on the other hand, if his horse be somewhat low in his forehand (which many first-rate hunters are), with very powerful action in his hind quarters; if ridden in hilly countries, or if at all disposed to be a puller, he will require to be at least two holes shorter in his stirrups; and his foot will be firmer if placed "home" in them, instead of resting on the balls. Above all things, he must acquire a firm, close, and *well-balanced* seat in his saddle, which is not merely necessary in leaping, but in galloping over every description of ground. A swagging seat in the last-mentioned act is sufficiently bad to make a great difference to a hunter in a severe chase; but when we picture to ourselves a horse alighting on the ground, after having cleared a high fence, and his rider alighting two or three seconds afterwards in his saddle, so far forward, perhaps, as to fall beyond the pillars of support, or backwards behind the centre of action and the part (just behind the shoulders) which ought to form the junction between the rider and his horse, we can readily imagine how distressing it must be to him, and how much a large fence, so taken, must exhaust him over and above what would be the case if he had had the assistance of a firm hand to support him on alighting; but which, however, with such a seat as we have been describing, no man can possess. The first requisite, then, for a person who follows hounds is the combination of a light hand with a firm seat; and fortunate is it for his horse, as well as for himself, if he possess it to the degree required to constitute a fine horseman over a country.

But as the science of war cannot be learned perfectly by anything short of experience in the field, neither can the art of horsemanship, as far as the sportsman is concerned, be learned perfectly in the riding-school or the academy. If our own observation did not confirm this fact, it would appear evident, from the variety of situations in which the man following hounds may be placed, in one individual run; and we will endeavour to enumerate them. First, there is galloping at very nearly full speed, not over turf as smooth as a carpeted floor, and with nothing beyond a daisy's head to come in contact with the horse's feet, but (*cursu undoso*) over every description and every variety of ground; over the high ridge and across the deep furrow; over ground studded with ant-hills, which, unlike the mole-hill, are often as hard as if they had been baked in an oven; over stones and flints, the latter so sharp as frequently to sever the sinews of a horse's leg so completely as to cause his toe to turn upwards, when his throat must be cut on the spot; over grips covered by weeds, and thus, if visible to the horseman, too often invisible to his horse; over deep underdrains, with rotten coverings, which frequently give way, and let in a horse nearly to his shoulders; down steep hills, stony lanes, through deep sloughs and treacherous bogs; and all this very frequently on infirm legs, as those of hunters which have been long in work are very apt to be.

Next come the "fences," as all obstacles to the follower of hounds are now technically termed; and let us just see of what they are composed. There is the new and stiff gate, with always five, and sometimes six bars, and each bar, perhaps, as firm against the force or weight of a horse and his rider as if it were made of wrought iron. Then there is the nobleman or gentleman's park-paling, full six feet high, and too often a turnpike road on the other side to alight on. The stiff four-barred stile, generally to be taken from a narrow and slippery foot-path, and not unfrequently on the declivity of a hill. The double post and rail fence, as it is called, too much to be cleared at one leap, in which case the horse has to leap the second rails from the top of a narrow bank, and sometimes from out of a ditch which is cut between them. Every now and then, in the rich grazing countries, which are far the best for hunting, and in which hounds run faster than in others, there is the ox-fence, which may thus be described: If taken from one side of it, there is, first, a ditch, then a thick and strong black-thorn hedge, and about two yards beyond it, on the landing side, is a very strong rail, placed to prevent feeding bullocks from running into the hedge, to avoid the œstrum or gadfly in the summer. This fence, covering a great space of ground, must be taken at once, or not at all, from either side on which it is approached. In these countries, from the goodness of the land, the black thorn attains great strength; but in places where it happens to become weak, instead of the ox fence, four strong rails are put, which, in addition to the ditch, makes also rather an awful fence; at least, if a horse do not clear it, he must fall, as the rails very rarely will give way. Some of these hedges being impracticable, from their thickness, the sportsman makes his way to one corner of the field, where he finds a flight of very high and strong rails, but without a ditch, and every now and then a sheep-fold. The former is somewhat of a more severe fence than it appears to be, owing to the ground on each side of it being either poached by cattle, or, what is worse, rendered slippery by sheep, which are driven into the corner to be examined by the shepherd, in the case of there not being a sheep-fold in the field. The sheep-fold or sheep-pen, as it is called in Leicestershire, is a still more serious undertaking. To get into it, the horse must leap four strong bars, about the average height of gates, and then, with a very short space to turn himself round in, must do the same thing to get out of it. Next comes the brook, from 12 to 20 feet in width, often bank-full, and sometimes overflowing its banks, which are often hollow, and generally rotten. In most of our best countries, few runs of extent take place without a brook or brooks being to be crossed; and no description of obstacle to which the sportsman is subject in crossing a country is the cause of so many disasters.

In what are termed the Provincial Hunting Countries, in contradistinction to Leicestershire, and the other chiefly grazing countries, timber, with the exception of stiles, is not so frequent, nor is the ox-fence to be seen at all; but there is comparatively more fencing, though chiefly hedges and ditches. In many of these, Dorsetshire in particular, the fences are generally what is termed double; that is, there is a ditch on each side of the hedge, which it requires a horse to be prepared for, by receiving, if not his education, a good deal of instruction in the country. In other parts of England—Cheshire and Lancashire, for example—we find fences that require an apprenticeship; they consist of a hedge and ditch, not of large dimensions, but in consequence of the former being planted on a cop or bank, a horse must land himself on the cop before he can get his footing to clear the fence, provided the hedge be on the rising side. Were he to spring at it from the level of the field, and clear the bank, together with the hedge and ditch, the exertion would be so great as soon to exhaust his powers. Those fences require horses very active and ready with their hinder legs, and also riders with good hands. In all strong plough-countries, as our fine loams and clays are termed by sportsmen, hedges with ditches (for the most part only one ditch) prevail. For height and width they are not equal, by much, to those of the grazing districts, but circumstances render them equally difficult and trying to the skill of a horseman and the judgment of his horse, and oftentimes still more so. In the former, although the fence is large (brooks excepted), the ground on the rising side is almost always sound and firm; whereas in deep-plough countries it is generally soft, and often, what is worse, it is sticky. Neither is this all. It very often happens that the headland of a field is ploughed to within a foot or two of the ditch, when a small ridge, or "balk," as it is termed in some districts, is left to prevent the soil of the field washing into the ditch. This ridge is often very perplexing to the horseman. He must either put his horse at the fence so as to clear all at once, or he must let him take his footing from off this narrow ridge, which, if his head be not in a very good place, and his rider's hand an indifferent one, makes even a small fence dangerous. The objection to a ploughed country also holds good as regards the other, the landing side of the fence. In the grass countries a horse alights on turf sufficiently elastic to break the concussion from the weight of himself and his rider, but seldom soft enough to sink him below his hoofs. On the other hand, in the ploughed districts, he is perpetually alighting in fallowed ground, or in that sown with wheat or other corn, which, particularly after a severe frost, is so far from being firm enough to bear his weight, that it sinks him nearly to the knees. This is very distressing, especially to a horse which carries a heavy man; and here the skill of the rider is shown in his preventing his jumping at fences of this description higher or farther than is absolutely necessary to clear them. To a man who follows hounds, indeed, this art of handing his horse easily over fences is one of the very highest value; and to the possession of it to perfection is to be attributed the extraordinary performance of hunters under some of our heaviest sportsmen (such as Mr Edge and his brother, Mr Richard Gurney, Sir Bellingham Graham, Mr Maxse, Lord Alvanley, and others), in fast runs of an hour or more, over strongly inclosed countries. Taking England throughout, there are fewer fences than there used to be; but more land is, year by year, being laid down in plough.

Walls are, we believe, the only fence met with in Great Britain which we have as yet left unnoticed. They are of two descriptions, namely, fast, by means of mortar, and loose, being built without mortar. The first do not often come in the way of the sportsman; and it is well that they do not, for, in the event of a horse striking them, they do not yield to his weight. The last, the loose walls, particularly those met with in Gloucestershire and Oxfordshire, are the least dangerous fences he can ride at; for, unless his horse be blown, or he is himself a very powerless horseman, they seldom resist him sufficiently to throw him down.

Their height varies from 3 to 5 feet; but as there never is a ditch on either side of them, and the ground is generally firm in the parts of those counties which are inclosed with walls; those even of the last-mentioned height may be taken with safety by a good horseman, on a horse that is accustomed to them, and is not distressed at the time by the pace; for, as "*it is the pace that kills*," so is it the pace that causes falls.

The following directions may be serviceable to a young beginner in the hunting field:—When hounds find and go away, place yourself well down in your saddle, on your fork, or twist, and dont be standing up in your stirrups (as formerly was the fashion, and the cause of many a dislocated neck), sticking out your rump as if it did not belong to you. Let your knee be not very far from straight, with your foot well out in front of it, and feeling in the stirrup as if it formed a sufficient fulcrum for your bodily strength to act upon in the assistance your horse may require from you. Be assured that the military seat, with the very long stirrup leathers, will not do here, however graceful it may appear on a parade. There must be a kind of *obstando* power in the rider to act against the preponderance of his horse, particularly at what are called drop-leaps, in very deep ground; or, in case of his making a blunder, or getting into false ground, in his gallop. Having got well away with the pack, keep your head up, with your reins in the left hand, and your whip in your right, held perpendicularly upwards, with the thong falling loosely through your hand, when it will be ready for all purposes. Cast your eye forward, to take a view of the country, and then on the body of the hounds, to satisfy yourself that they are well settled to the chase. And now comes the young fox-hunter's trial. *You must neither take liberties with the hounds nor with your horse.* Ride wide of, that is, on the left, or on the right of, the former, turning as you see them turn, and never find yourself exactly behind them, on their line; and no matter how perfect may be the latter, never trust him to himself, nor upset him by going too fast for him, or, in other words, over-marking him for pace. However good his mouth, never ride him in chase with quite a slack rein, for, independently of your own safety, it is not giving him a fair chance. He requires your support, and he should have it.

In riding to hounds, there is much to be gained by what is termed picking out your country. Avoid going straight across land highly ridged, and consequently deeply furrowed, if possible to avoid it, but rather take your line diagonally. If the furrows are very deep and holding, make for the side, or the headland, where, of course, it is comparatively level ground. Even if it takes you a little out of your line, you will find your advantage in this, for you may increase your rate of going, and that with ease to your horse, more than equal to the extra distance you have to go. If your horse appear somewhat distressed, it is on a headland, or still more on a long sideland, that you have a good opportunity of recovering him; and here you may have recourse to the old-fashioned style of riding a hunter. You may stand up in your stirrups, catching fast hold of your horse's head, and pulling him well together, when you will find that, without slackening his pace, he has recovered his wind, and can go on. Avoid deep ground as much as possible; but when in it keep a good pull on your horse, and by no means attempt to go so fast over it as you have been going over that which was sound. After Christmas, turnip fields should be skirted, if possible; for, by reason of the many ploughings they receive at seed-time, the land sown with turnips becomes so loose and porous after severe frost, that it cannot carry a horse. Also avoid *crossing* fallows, or land sown with wheat. If obliged to go athwart them, get on the headland; or, if you ride straight down them, choose the wettest furrow you can see. It is sure to have the firmest bottom, which is proved by the water standing in it.

As no man can say where a fox-chase will end, have an eye to your horse, and endeavour to give him all the advantages in his favour that the country and the pace will admit of. Next to a judicious choice of your ground, is quickness in turning with hounds, as the difference between riding inside and outside of them, in their turns (be it remembered hounds very seldom run straight) is very considerable indeed; and to a certain degree corresponds with what is called "the whip-hand" in a race. Again, if you wish to stand well with the master of the pack, and to obtain the character of a sportsman, observe the following rules:—Never press upon hounds, even in chase. When they have lost the chase (in other words, when they are at fault), pull up your horse and keep wide of them; and, in the words of a celebrated old sportsman, "*always anticipate a check.*"

Never, for the sake of displaying your horsemanship or your horse, take an unnecessary leap when hounds are running, nor a large one when a smaller is in your view, unless the latter take you too much out of your line, or for a reason which we shall presently give. If your horse is a good timber leaper and not blown, prefer a moderate timber fence to a rough and blind hedge-and-ditch fence, as less likely to give you a fall, neither will it take so much out of your horse. But when your horse becomes distressed avoid timber, for if he do not clear it he will give you a worse fall in that state than if he were quite fresh. A blown horse falls nearly as heavy as a dead one. There is, however, another precaution to be observed with horses a good deal beaten by the pace. Have an eye, then, rather to the nature of the ground on which it is placed, than to the size of the fence; that is, prefer a good-sized fence, where you see firm ground for your horse to spring from, to a small one where it is soft and sticky. Moreover, a distressed horse will often rise at a fence of some height and appearance, whereas he will run into, or, at all events, endeavour to scramble through, a small one. If you decide upon the smaller place, let him go gently at it, as he will be less likely to give you a fall; at all events, he may not give you so bad a one as if you went fast up to it. Some horses get out of scrapes better than others; but it is as well not to give them an opportunity of showing their prowess in such matters, and one of the worst faults they can possibly have is not to care for falling.

A chief requisite to a good rider across a country is courage, one of the most common qualities of human nature; and another is coolness. No man, when flurried, can do any one thing well; but when we consider the variety of objects that the sportsman following hounds has to attract his notice, and the many obstacles he may have to encounter, it is evident that, according to the old adage, "he must have all his wits about him." The perfection of fine horsemanship in the hunting-field, then, is in a man riding well up to hounds, when going their best pace over a stiff country, and yet appearing to be quite at his ease, and his horse, as it were, sympathizing with him in his calmness. Such a man (and there are some such in every hunt, but not many) is capable of taking every advantage that can be taken of country, hounds, and all obstacles which appear to oppose him in his career. Another signal advantage to the sportsman also arises from his coolness in these moments of no small mental as well as bodily excitement and exertion. He is able to observe the beautiful working of the hounds, which is displayed to advantage with a burning scent; and he enjoys it the more in consequence of the superiority of his horsemanship having placed him in a situation where he is not molested by the crowd.

Although speed in the hunter is now absolutely necessary, from the much increased rate of hounds, yet it is equally necessary, in most of our hunting countries, that he should be a perfect fencer as well, and that his rider should be an accurate judge of the extent of his fencing powers. Thus it often happens that horses, not equal in speed to others, get quicker over a stiffly-inclosed country than they do, because, by the means of their superior fencing, they are able to cut off angles and go straighter. In fact, there are frequent instances of one individual sportsman beating every other in the field, and being alone throughout a run, merely by clearing a great fence in the direct line of the hounds at starting; in avoiding which, so much ground had been lost by the rest of the field, that it could not be recovered by them until the chase was ended.

It is a common saying among steeple-chasers, that five times as many horses rick their backs at a grip or small blind fence, which they hardly care to rise at, than at a rasper; and from the effect of the exertion of leaping, in horses, which is pretty accurately ascertained by the observation and experience of sportsmen, some rather curious facts are drawn. A very large fence, as has been before observed, exhausts a horse, or, in the language of the field, "takes a good deal out of him;" nevertheless, a hunter becomes sooner distressed over quite an open country, when the pace is very severe, than he does over an inclosed one, provided the fences are not very large indeed. This is accounted for in two ways: First, fences check the speed of hounds, and consequently the speed of horses. Secondly, the mere act of pulling or gathering a horse together, to shorten his stride previously to his taking his leap, is a very great relief to his wind, as we know from the effect a good pull at his bridle, towards the end of his course, has on that of the race-horse. At several kinds of fences, likewise, it is necessary that he should be pulled up nearly, if not quite, into a walk, to enable him to take them with safety, such as fences by the sides of trees, hedges with ditches on each side of them, particularly if they are what is termed "blind:' in short, all places known in the hunting vocabulary as cramped places, as well as now and then a timber fence, which must be taken nearly at a stand. And it was the old system of taking all upright fences, such as gates, rails, stiles, and hedges without ditches, at a stand, that enabled the low-bred hunter of the early part and middle of the last century to live with hounds as well as he did live with them. The very short time that it takes for a horse to recover his wind, to a certain extent, might be proved by a reference to stage-coach work. Previously to the perfect manner in which it was latterly performed, and the superior condition of the cattle, from their owners having at length found out how to feed them, it was not unusual for a coachman to have a high blower, as a thick or bad-winded horse is called on the road, in his team, which might scarcely be able to keep time. If he found him distressed, he would pull up his coach on the top of a hill, and draw back the distressed horse from his collar. But how long would he keep him in this position? Why, not many seconds, before he would be sufficiently relieved to proceed. Thus the country of all others which puts the physical powers of horses to the greatest test in following hounds, is one which is hilly, and totally without fences, of which the Sussex South Downs, in the neighbourhood of Brighton, may be taken as a sample. Nothing but a thorough-bred horse, and a good one too, can live quite alongside hounds, going their very best pace, more than half an hour over such a country as this, and very few can do even so much, if they carry more than average weight. The open ploughed countries, such as great part of Wiltshire and Hampshire, are for the same reason very distressing to horses, and require them to have a great share of blood; but hounds do not, neither can they, run so fast over ploughed ground, as over old, or maiden turf, which the Sussex Downs are clothed with. In the first place, the scent is seldom so good; secondly, the ground is not only not elastic, which the other is, but it impedes the progress of hounds from two other causes; its surface is less even, and the soil of all ploughed land sticks more or less to the feet of hounds; or, in the language of the huntsman, it "carries" invariably after a slight frost on the previous night.

We now resume our advice to the young fox-hunting horseman: It is the practice of all first-rate horsemen over a country—and no man was a greater advocate for it than Sir Harry Goodricke—to ride slowly at the majority of fences. For example, if the ditch be on the rising side, you may cause your horse to put his feet into it before he rises at the hedge, if you hurry him at it. Should the ditch be on the landing side, the case is somewhat altered, as the pace you ride at must be regulated by its width. If you have reason to believe it is of moderate width, do not go fast at the fence, because it will cause your horse to leap further than he needs to leap, and of course help to exhaust him. But if, when within a few yards of the hedge, going slowly at it, you perceive the ditch is a broad one, "put in some powder," as the modern sporting term is; that is, urge your horse by the hand and spur, and he will be aware of what you wish him to do, namely, to extend himself so as to clear a wide space of ground. If the ground on the landing side be lower than that on the rising side, causing what is called "a drop leap," or even if the ground be not lower, but soft or boggy, your horse will look for assistance from you on alighting, which you should give him by throwing your body back, having at the same time a resisting power from your stirrups. But another precaution is necessary when the ditch is on the rising side, or indeed with all fences except those (as will be hereafter named) which require to be ridden quickly at. This is, to fore-shorten the horse's stroke so as to enable him to gather himself together for the spring, or he may misjudge his distance, and get too near to his fence to rise at it. In fact, to judge accurately of the distance from the fence at which the spring should be taken, is a great accomplishment in a man and a horse. In the former, it is the result of experience and a quick eye; with the latter, it is in great measure dependent on temper; and consequently violent horses—"rushing fencers," as they are termed—never perfectly acquire it. It is a serious fault in a horse to take his spring sooner than he need take it; and perfect fencers go close up to their fences before they rise at them, particularly to hedges when the ditches are on the landing side. Horses, however, of hasty tempers, particularly well-bred ones, with great jumping powers, cannot always be made to do so. Neither will they save themselves by walking into, or pushing through, places which do not require to be jumped; on the contrary, many otherwise excellent hunters will scarcely suffer a brier to touch their legs. A good bridle-hand here comes into play, more especially with horses who are rather difficult to handle, either from too fine a mouth, or a loose, ill-formed neck. It is difficult, however, to offer instruction here, as there ought to be an absolute interchange of feeling between the instructor and the instructed, to render them intelligible to each other; but we will endeavour to make ourselves understood:—When you approach a fence with a horse of this description, you should leave him as much to himself as you find it prudent to do, particularly when within a few yards of it. If you are obliged to check his speed, do so with as light a hand as possible; and if he shows a dislike to be much checked, by throwing up his head, or otherwise, drop your hand to him, and let him go. He has by this time most probably measured the fence by his eye, and it may not be safe to interfere with him.

Double fences, particularly with a horse not quite perfect in his mouth, and the setting on of his head, try the hand of the horseman. The first part of the fence, usually a ditch, may be cleared without any difficulty, and so may the second, if visible; but it often happens that neither horse nor rider is prepared for the second. Here it is that, in our opinion, lifting a horse is to be recommended, and in very few cases besides. Our objection to it arises from the horse being led to expect it; and if he do not get it at the critical moment, it may mislead him. In fact, it requires a hand nicer than common to make a practice of lifting a horse at his fences. Nevertheless, in the instance we have alluded to, the unforeseen ditch, it is useful; as also towards the end of a run, when a horse, from distress, is given to be slovenly at his fences, if not disposed to run into them. In leaping timber fences, we consider the attempt to lift a hunter dangerous; for a horse becomes a good timber-leaper from confidence; and if he finds he is to wait, as it were, for your pleasure for him to rise at a gate or a stile, he will be very apt to make mistakes.

We have already observed that timber fences are the most dangerous of any, by reason of their general strength; if a horse strikes them with his fore legs, or gets across them, as it were, by not being able to bring his hinder quarters clear of them, they are nearly certain to cause him to fall. And he falls from timber in a form more dangerous to his rider than when he merely stumbles and eventually falls, by putting his feet into a ditch. In the latter case, his fore quarters come to the ground first; and by breaking the force of the fall, the rider has time to roll away from him before he himself rolls over, should the violence of the fall cause him to do so. In the former, if the timber be strong enough firmly to resist the weight and force of a horse that strikes it with his fore legs, especially if above the knees, the first part of his body which comes to the ground is either his back or his rump. Should the rider then not be thrown clear of him, he must be made of hard materials if no bones are broken, or some serious injury sustained. All this, then, enforces the advice we have already given, of avoiding strong timber with horses not perfect at leaping it, as much as may be compatible with keeping your place with hounds; and still more so with horses, how perfect soever they may be at it, that are blown, or very much distressed. It likewise induces us to point out the best and safest method of riding at this description of fence.

Never ride a horse fast at a timber fence, unless it be a low one, with something wide to be cleared on the landing side. If a man or boy is seen exercising himself in jumping heighth, you do not see him run quickly at it, nor does he run over any considerable space of ground before he springs. On the contrary, he only takes a few steps, and those at a moderate rate. Never, then, ride your hunter fast at gates, stiles, &c., unless in the one case alluded to. Mr Thomas Assheton Smith, who was for many years at the head of the Quorndon (Leicestershire) Hunt, and whose riding of Jack o' Lantern in particular was justly regarded as the very essence of horsemanship, never rode fast at any fences, brooks excepted, and then only under circumstances which will be explained when we treat on that part of our subject. When riding at timber, however, take a firm hold of your horse's head, chiefly by the aid of the bridoon, if his mouth is good enough for it; and let him understand, by assuming an air of resolution on your part, that you not only mean him to leap it, and that you will not suffer him to turn his tail to it, but that it is something at which his best energies will be required of him. But above all things do not interfere with his stroke or stride, unless absolutely called upon by some peculiarity of the ground, such as a grip on the headland, or a small ditch on the rising side. A horse making up his mind to leap a timber fence, will of his own accord regulate that matter, and gradually gather himself together on his haunches, previous to being required to take his spring. He will also, if you let him, often make choice of his pace at which he goes up to a gate, &c. It is true the deer can clear a greater height in its trot than in any other pace; but a horse prefers the very slow gallop, or canter, when thus called upon to exert himself; for if he do trot to any upright fence, we generally see him break into a canter in the last few yards. As the fulcrum for the spring comes from behind, the canter is the most natural pace, the haunches being at this time more under him.

The same instructions to the horseman hold good with regard to stone walls as to timber fences, at least to those met with in England, which are loose, and without ditches. But in several parts of Scotland the case is different, as the sportsman very frequently has to encounter walls with ditches on one side or the other of them. In consequence of their being placed at some distance from the wall, to prevent the water which runs down them undermining the foundation of it, there is frequently room, when the ditch is on the rising side, for a horse to leap the ditch, and take a second spring from the intermediate space, and so clear the wall. But when he has to leap the wall, with the ditch on the landing side, it becomes a very difficult fence, and must be ridden at with judgment. If the ditch be not too far from the wall to come within the stretch of a hunter, he should be ridden quickly at it, and well roused by the rider, to make him extend himself sufficiently; but if it be too far, he should be put very slowly at the wall, so as to enable him to drop, with his hinder legs at least, on the intermediate space, and from thence spring over the ditch. This fence is very trying to horses not accustomed to it; and with those which are, one fact becomes apparent, namely, that the mere holding the reins of a bridle does not constitute what is called "a hand" on a horse. A workman with a "finger" is wanted here.

In riding at every description of timber your seat as well as your hand requires attention. You have already been told on what part of your horse you ought to sit, namely, in the middle of your saddle, which should be placed close to the shoulder bones, when your seat will be most secure, from its being just in the centre of motion when your horse springs at his fence; as, in the rising and falling of a board placed *in equilibrio*, the centre will be most at rest. Your true seat, indeed, will be found nearly in that part of your saddle into which your body would naturally slide if you mounted without stirrups. But other security than this is required to insure safety over very high fences. It is not the horse's rising that tries the rider's seat; the lash of his hinder legs is what ought to be chiefly guarded against, and is best done by the body's being greatly inclined backward. Grasp the saddle lightly with the hollow or inner part of your thighs, but let there be no stiffness in any part of the person at this time, particularly in the loins, which should be as pliant as those of a coachman on his box, when travelling over a rough road. A stiff seat cannot be a secure one, because it offers resistance to the violent motions of the horse, which is clearly illustrated by the cricket-player. Were he to hold his hand firm and fixed when he catches a ball struck with great force, his hand or arm would be broken by the resistance; but by yielding his hand gradually, and for a certain distance, to the motion of the ball, by a due mixture of opposition and obedience, he catches it without sustaining injury. Thus it is in the saddle. A good horseman recovers his poise, by giving some way to the motion, whereas a bad one is flung from his seat, by endeavouring to be fixed in it. In old times, when hunters were trained to leap all upright fences standing, these precautions were still more necessary, because the effect of the lash of the hinder quarters was more sudden and violent, in consequence of the horse being so close to his fence, that he rose perpendicularly at it, and not with the lengthened sweep of a flying leap.

Although Virgil, in his third *Georgic*, speaks of not suffering the brood mare to leap fences (*non saltu superare viam*), we find nothing on this subject in the classics to induce us to believe that the ancients, although they hunted, were given to ride over fences. Here they sustained a loss; for we know few more delightful sensations than that experienced in the act of riding a fine flying leaper over a high and broad fence. Nothing within the power of man approaches so nearly to the act of flying; and it is astonishing what a great space of ground has been covered at one leap by horses with first-rate horsemen on their backs. In the grand Leicestershire Steeple-Chase of 1829, a gray horse, called "The King of the Valley," the property of Mr Maxse, and ridden by the celebrated "Dick Christian" of Melton-Mowbray, cleared the previously unheard-of space of 33 feet; and in the "Grand National" at Liverpool, Mr Elmore's Lottery cleared 33 feet over the wall erected in front of the stand; Mr Tilbury's Culverthorpe jumped 37 feet over hurdles at Newport-Pagnell; and at Leamington Captain Little's Chandler cleared 39 feet over the brook, in which three or four horses and their riders were scrambling at the time. Yet, after all, the most extraordinary fact relating to the act of leaping in horses, is the power they have of extending themselves by a second spring, as it were, when they perceive something on the further side of a fence, for which they were not prepared. That they occasionally do this under good horsemen, all good horsemen of experience can vouch for; but whence the fulcrum is derived it would be difficult to determine. All horses which have been in Leicestershire, and other counties where the fences are large and wide, become more or less accomplished in the act of throwing themselves forward, as well as springing upward, causing a very pleasant sensation in the rider, as well as an assurance that he is not likely to drop short into the ditch or brook. The most accomplished hunters generally touch their fences, and many of the Irish horses carry this habit of thrusting themselves with their hind legs off a bank to such an extent, that the rider feels as if he were never coming to the ground again.

We have already said that brooks stop a field more than any other description of fence, and for the following reasons:—Very few men, and still fewer horses, like jumping brooks. In the first place, as concerns the rider, they are very apt to injure his horse by a strain, or a bad over-reach; secondly, water is deceiving as to the extent of it; thirdly, a wide brook takes much out of a horse; and, lastly, the banks often give way, after the horse supposes he has landed himself; and although it is easy for him to get into a brook, it is often very difficult for him to get out of one. Few horses become very good water-jumpers, unless they have been hunted a good deal in countries where brooks abound, and also have been fortunate in not getting into one of them in their noviciate; and Lottery, the most thorough steeple-chaser under all weights that was ever crossed, invariably bungled at them. For this reason, it is a hazardous experiment to give a large price for a hunter, how high soever may be his character, that has been only hunted in counties like Hampshire or parts of Wiltshire, where there are no brooks but such as, from the soundness of their bottoms, horses may walk through. We have already stated the most likely way to make a young horse a good brook-jumper, a very superior accomplishment in a hunter, and chiefly to be attained by his acquiring confidence.

There is one other untoward circumstance attending leaping brooks with hounds. They are, for the most part, met with in the middle of a field, and it often happens that, until the horseman arrives on the very brink of them, he cannot form a correct estimate of their nature or extent. They also vary much in both these respects, we mean in the soundness or unsoundness of their banks, and in their width, in the space of a few yards; so that it is in some measure a matter of chance whether you have to leap a wide brook or a narrow one. But, then, it may be said, you can always satisfy yourself on these points. True; you may do so; but what would too often be the consequence? Why, if you show your horse a brook before you ride him at it, it would too frequently happen that he would not have it at all; add to which, whilst you were doing this, on a good scenting day, the hounds would get a long way a-head of you. Besides, the *vis vivida*, or momentum of the horse's gallop, so necessary to get him well over wide brooks with rotten banks, is wanted, but in this case would to a certain extent be lost; and if he is once pulled up, and turned round, it is not so readily acquired again, as he is always more or less alarmed, after having got a sight of what he is going to encounter. Wide brooks, then, with uncertain banks, are the only fences which should be ridden very fast at; for, exclusive of the advantage the horse gets from the impetus derived from the speed should he fall on the other side from false ground, he will generally save himself from dropping backwards into the brook, an object of no small importance to him, as also to his rider. There are, however, exceptions to the rule of riding *fast* at brooks. When they are not wide, and the banks are sound, it takes less out of a horse to put him at a moderate rate at them. Neither should he be ridden quickly at them when they overflow their banks, as it will then require all his circumspection and care to know when, or where to spring from, to cover them. In fact, overflown brooks are rather formidable obstacles; but (a fine trial of hand) numerous instances do occur in the course of a season, where they are leaped when in that state by some of the field, but not by many.

Although, when the sportsman rides over a very wide brook, or any other fence which requires much ground to be covered, he has a certain hold by his bridle: yet, as may be supposed, it is very unequal to the weight of his own body, increased by the resistance of the air. How happens it, then, that his horse does not leap from under him? or, at least, how is it that, when the horse alights, the rider alights in the very same spot in the saddle on which he sat when his horse rose at it? The fact is, his body so far partakes of the speed of his horse, and increases in common with it, that, with very little assistance from his bridle-reins, he keeps himself in his proper place. If it were not so, what would become of the rider in the circus, who leaps directly upward, through a hoop perhaps, or over his whip, whilst his horse is going at considerable speed? He would, of course, alight upon the ground, perpendicularly, under the point at which he sprung from his saddle. It is evident, however, that on leaving the saddle the body of the rider has equal velocity with that of the horse; and the spring, which he takes perpendicularly upward, in no degree diminishes the velocity; so that, while he is ascending from the saddle, he is still advancing with the same speed as his horse, and continues so advancing until his return to the saddle. In this case the body of the rider describes the diagonal of a parallelogram; one side of which is in the direction of the horse's motion, and the other perpendicularly upward, in the direction in which he makes the leap. From these facts, these striking instances of the composition of motion, then, may the advantages of good, and the disadvantages of bad, horsemanship be appreciated; and as it appears that the motions of the rider and his horse are so intimately connected and in unison with each other (for were the circus rider to project his body forward, in his leap through the hoop, as he would do if it were on the ground, he would alight on his horse's head or neck, or perhaps before his head, for he would then advance forward more rapidly than his horse), the importance of a steady seat and a good hand is apparent, and accounts for some men crossing a country on middling horses, quicker and better than others do upon really good ones.

Having spoken of overflown brooks, and being aware of the many fatal disasters that have occurred to sportsmen in water, and the narrow escapes of others from drowning by crossing flooded rivers, within the last twenty years, we are surprised that the exercise of swimming horses in the summer months is not more generally resorted to. It was practised by the ancients; for we find Alexander swimming the Granicus with thirteen troops of horse. But the horses should be practised in swimming as well as their riders, or it would not avail the sportsman so much, as we know some horses are very much alarmed when they lose their legs in water, and often turn themselves over. That the act of swimming on horses is a most simple and safe one to those who practise it, may be proved at any of our watering places in the summer, where boys swim them out to sea, two at a time, changing their seats from one to another with the greatest ease. We observe they generally lean their body forwards, so that the water gets under it, and partly floats it, interfering as little as possible with the horse's mouth; at all events, never touching the curb rein. When the sportsman or the traveller has occasion, or is accidentally called upon, to swim his horse through deep water, and the banks will admit of it, he should enter it as gradually as possible, as not only will his horse be less alarmed at the loss of his footing, but less liable to turn himself over in it. Thus in fording a brook too wide to leap, and with a soft bottom, a horse should be ridden *very slowly* into it, which will enable him to get his hinder legs well under his body before he makes his spring to ascend the opposite bank; which he cannot do if he enter the brook quickly.

As the young sportsman may be induced to "make his own horses," as the term is for qualifying them for the appellation of hunters, it may not be amiss to offer him a few words of advice. Be careful, the first season, how you ride them at very cramped places, especially where there is timber, for they cannot be expected to be *au fait* at such things; and many of the worst falls that some of our hard-riding sportsmen have experienced, have been from expecting young horses to do what old, or at least experienced ones, only can do. Avoid also taking the lead with hounds, especially if they run hard, with a young horse, for it may cause him to refuse a big fence which he might have followed another horse over, and thus become a refuser ever afterwards. Although horses do not understand languages, they understand the arbitrary signs of their masters or riders; and if a young hunter makes a slovenly mistake with you at a fence, he should be corrected with either spur or whip, and also *by the voice.* The merely calling out to him, or exclaiming, "For shame! what are you about, eh?" accompanied by a slight stroke of the whip, has often a very good effect, and will be visible at the next fence, when he will be more careful where he puts his feet, and take a greater spring. A horse knows his errors; also, when he is corrected, and when cherished, each of which he should be subject to in their turns; but as, according to the old adage, a coward and a madman are equally unfit to be horsemen, the correction of a young hunter should not be severe. Nothing would be more likely to make him what is called a "rushing," and consequently an unsafe fencer for the rest of his life, than beating him *severely*, for any trifling faults he may commit in the field. Martingals on hunters and racers are now generally condemned; but, in our opinion, more generally than they deserve to be, particularly during the first season of a young horse, as a long martingal serves to steady his head, if he is a little impetuous, and saves him many falls, which, putting his rider out of the question, are injurious to him, as all horses become safe fencers, in a great measure, by having confidence in themselves, which falls must necessarily shake. All horses, indeed, whose necks are weak and loose, may be ridden with advantage by the aid of a martingal on the bridoon rein, *the rings coming quite up to their jaws*, when it cannot interfere with their galloping or their leaping.

The perfect command of a horse in the hunting field is in nothing more essential than in passing through half-opened gates, and many have been the bad accidents that have arisen from the want of it, horses being often stuck fast between the gate and the post, to the no small injury to their rider's legs or knees. Indeed the being handy in opening a gate, is no trifling accomplishment in a hunter; and here a few lessons in the school may be of advantage to him. He would there be taught to obey the leg as well as the hand; and, by a slight touch of the spur, would throw his haunches round to the left, on his rider unfastening the latch with his right hand, and thus enable him to throw the gate behind him, and pass through it. This has reference to gates that open *towards* the horseman; such as open *from* him require not the horse's aid. But it often happens when a horse is blown, or beat, that unless he have a very good mouth, he will hang upon a gate, and nearly prevent his rider from opening it at all. One precaution, however, should always be taken with gates; the rider should never trust to catching the topmost bar, or what is called the head of the gate, but should pass his hand inside of it, when he will be certain to come in contact with some part of it.

Falls.—There is a proverb, and a true one, which says, "He that will venture nothing, must not get on horseback." All men, however, who ride a-hunting are subject to falls, but those who ride near the hounds, or "hard," as the term is, seldom escape without having several in the course of a season. It is well, then, that the young sportsman should know that there is an art in falling, as well as in preventing falls. This consists in getting clear of the horse as soon as possible, which a man in the habit of falling has a better chance to do than one who runs less risk of it, having greater self-possession at the moment. Next to a horse coming neck and croup over a high timber fence, a fall in galloping at full speed is most dangerous, and apt to dislocate the neck, by the head coming first to the ground; and from the velocity of the fall, the rider has no time for precautions. However, even in this case he should endeavour to put out one hand, if not both, to break the force of the fall, as well as to act in resistance to his head coming first to the ground, and receiving the whole force of the concussion. By so doing, it is true, the collar-bone stands a great chance of being fractured; but that is an accident merely of temporary inconvenience, and unattended with danger, whereas a dislocated neck is very rarely reduced. But it is a curious fact, that there are fewer instances of broken necks in the field in the present age than there were nearly a century ago, notwithstanding that for one man who rode a-hunting then, there are fifty now; and the pace of hounds, as well as style of riding, much altered as to speed. This has been accounted for in two ways; first, the modern sportsman sits, for the most part, down on his saddle, whereas the sportsman of olden times stood up in his stirrups, and, when his horse fell with him in his gallop, was nearly certain to fall on his head. Secondly, he did not ride the well-bred, clever-actioned horse that the modern sportsman rides, which would account for his falling oftener in his gallop, and particularly as the surface of the country, in his day, was very uneven and uncultivated compared to what it now is. Neither was the hunting cap of much service to him in accidents of this description. On the contrary, from its being so low in the crown, as it was then made, coming in immediate contact with the top of the head, the concussion was greater if he were thrown upon his head, than if it had been cased in a hat which, from the depth of it, would break the fall.

In all falls, the horseman should roll away from his horse as soon as he possibly can, lest in his struggle to rise again he strike him with his legs or head. Coolness in this hour of peril, likewise serves the sportsman in another way. Instead of losing hold of his reins, and abandoning his horse to his own will, as the man who is flurried at this time invariably does, he keeps them in his hand, if not always, perhaps in nine falls out of ten, and thus secures his horse. It was the remark of a gentleman to whom we have before alluded, and who (*singulus in arte*) was, from his desperate system of riding, and despite of his fine horsemanship, known to have more falls than any other man during the time he hunted Leicestershire, that nothing had so low an appearance as that of a man running on foot over a field, calling out "Stop my horse!"

Before quitting this part of our subject, it may be well to observe, that in cases of bad falls, particularly those affecting the head, where the lancet cannot be *immediately* had recourse to, a large wine glassful of equal parts of *strong* vinegar and water, drunk by the sufferer, is found to be very efficacious, from the revulsive powers of the vinegar acting on the general circulation of the system. In countries where there is much timber to be leaped—stiles particularly—calkins to the shoes of the hinder feet of a hunter should never be omitted, as should those feet slip under his body, the fulcrum to spring from is lost, and a fall nearly certain.

We have only a few words more to offer to the young sportsman. Nature is invariably the standard of excellence, and unless she have endowed you with a cool head, a vigorous body, and a stout heart, you will not long distinguish yourself in the hunting field as what is now termed "*a first-flight horseman.*" You may sing with Hector,

> "———*The foremost place* I claim,
> The first in danger, as the first in fame;"

but you will not obtain it unless you possess the above-named requisites. But having them, do not consider the following admonitions unworthy of your notice: "Never ride at impenetrable or impracticable places; you may get over or through them with a fall, but your horse will surely be the worse for the attempt, and will the sooner sink under you in a good run. Never abandon your horse to himself over any ground, but be sure to hold him fast by his head, either up or down hill, and in soft ground. If you doubt the effect of a tight hand at these times, ask the first Newmarket jockey you meet, and he will fully satisfy your doubts. In the daring movements of that "*lawless moment,*" which the first start after hounds, in some countries, may now be termed, from the desperate attempts hard-riding men make to get the lead, do not fail to have your eyes about you, and also keep a good command over your horse. In plain English, *do not ride over any man.* Some of the worst accidents to sportsmen have arisen from this cause. In the first place, one man will often ride so close to another who is going to leap a fence, that if the first horse falls, the second is almost certain to leap either on or over him and his rider, as he can rarely be pulled up, or even turned, in so short a space. But even should the second man see the first man's horse in the act of leaping the fence, he should allow him some time to get away from it, for in the event of his clearing it, it is still possible he may fall, by stumbling over something after landing; stepping into a grip or rut, or into false ground, all of which he is subject to, but more especially towards the end of a chase, when, of course, his strength and action are reduced. It is better, if you can, to take a line of your own than to follow any one at this time, as your horse is now fresh; and, by not having cause to pull him up to let others go before you, you have a better chance to get a good start, which gives you a great advantage. When once alongside the pack, quit them not until they have finished their work, or at least as long as your horse can go without trespassing too hard on his powers. If, however, you get the lead and can keep it for forty minutes *best pace over the grass,* with rasping fences and two wide brooks in your way, the laurels Cæsar won would be weeds, and withered ones too, compared with those which would, for that one day, be yours.

There have been, and are now, some splendid specimens of horsemanship, and the management of horses in other ways, amongst servants, and it appears there always were such. Amongst the celebrated ones of antiquity we find the following, moving in this humble sphere:—Automedon, servant to Achilles; Idæus to Priam; Metiocus to Turnus, king of Rutuli; Myrtilus to Œnomous, a son of Mars; Ceberes to Darius; and Anniceris, servant to Cyraneus. And why should not the servant, by practice, become as fine a horseman as his master? The question appears to be easily answered, namely, that the chances are equal, with equal instruction and experience. But such has not been found to be the case; and although amongst the various huntsmen, whippers-in, and what are known by the appellation of second-horse-men (namely, those grooms who ride horses with hounds to supply the place of those their masters ride when they become fatigued, a most humane as well as economical plan with all who have a stud of hunters), some super-excellent horsemen may be found, the generality of servants are deficient in that first essential to good horsemanship, a fine or sensitive hand. Nor is this a matter of surprise. The nervous influence proceeding from the organs of touch may be said chiefly to constitute what is termed the "hand" of the horseman; and that influence may easily be supposed to be greater in a person whose situation in life has not subjected him to rough and laborious employments which must necessarily tend to deaden it. Until of late years the seat of servants was unfavourable to a good hand on their horse, as they, with very few exceptions, rode with too short stirrups, and, consequently, by being not well placed in their seats, were perpetually interfering with their horses' mouths from their unsteadiness. So fully aware of these objections was the late Mr Childe of Kinlett Hall, Shropshire, that he had only one servant that he suffered to mount the horses he himself rode, and that was William Barrow, afterwards more than twenty years huntsman to the late Mr Corbet in Warwickshire, and who was remarkable for his fine bridle-hand. Mr Osbaldeston also seldom intrusted his best horses to any one but Jack Stevens. Notwithstanding this, it may fairly be maintained, that, from the fact of the comparatively small number of good horsemen who have obtained instruction from the schools, there is more of nature than of art in the acquisition of skill and talent on the saddle.

Saddles and bridles form no unimportant feature in the equestrian art, as well as in the establishment of a sportsman. Nothing sets off the appearance of a horse and his rider more than a good saddle and bridle; nor does anything contribute more to the comfort and safety of the latter than a well-made, roomy saddle, with spring bars for the stirrup-leathers—stirrups rather heavy than otherwise, and sufficiently large for the feet. Some persons, not contented with the spring bars, require spring stirrups as well; but, in our opinion, no man can hang in a common stirrup, provided he do not wear thick boots nor use small stirrup-irons. Of the various sorts of bridles, the snaffle is most in use on the turf, and the curb for military horses, hunters, roadsters, and coach horses. Not one hunter in twenty has a mouth good enough for a snaffle only, although there are a few horses in every hunt that will not face the curb. Some, however, go very well on the snaffle up to a certain period of a run, when all at once they require the assistance of the curb. Such horses should be ridden with a double bridle, so that the rider may have recourse to the curb-bit when wanting.

There is often great nicety required in fitting a horse with a bridle, if irritable in his temper, or a very hard puller. If the former, he must have a bit of just sufficient severity to control him, and not anything more. The one called the "Pelham" is well adapted to horses of this description, as it partakes of the double properties of snaffle and curb. With very hard pulling horses, the curb to a severe bit must be used; but the evil of this is, that, after a certain time, the mouth thus acted upon becomes "dead," as the term is, and the horse is unpleasant to ride and difficult to turn. To remedy this, three players should be attached to the port of the bit, which, by hanging loosely over the tongue, keep the mouth alive. A bridle of this description, very long in the cheek, is known in the hunting world as the "Clipper bit," being the one in which that celebrated horseman Mr Lindow rode a horse called the Clipper several years over Leicestershire, in which far-famed county he was supposed to be the best hunter going. If a horse rushes at his fences, a moderately tight nose-band is useful, as also to prevent his opening his mouth, and snatching at his rider's hand. The less a horse opens his mouth in his work the better, as it tends to make it dry; whereas, it cannot be too moist for his own good. Bits very high in the port are of course the most severe, owing to the increased purchase; but with every description of bits care should be taken that they are sufficiently wide for the mouth, so as not to press against the horse's cheeks, and that the headstall is sufficiently long to let the bit drop well into the mouth.

As we read in the 22d chapter of Genesis, 3d verse, that "Abraham rose up early in the morning, and *saddled* his ass." saddles of some sort must have been used in very early days; but few things appear more extraordinary to those persons who look into ancient history than the fact of saddles *with stirrups* being a comparatively modern invention. Although a French translator[1] of Xenophon by an oversight makes a governor of Armenia hold the stirrup of the Persian king when he mounted his horse ("Il lui tenoit *l'etrier* lorsq'il montoit à cheval"), it is well known that the ancients had no stirrups, but that men of rank among them were accompanied by a person whose office it was to lift them into the saddle, whom the Greeks called ἀναβολευς, and the Romans *strator*. There is no mention of stirrups in any Greek or Latin authors, no figure to be seen in any statue or monument, nor any word expressive of them to be met with in classical antiquity. In the celebrated equestrian statues of Trajan and Antoninus the legs of the rider hang down without any support; whereas, had stirrups been used at that time, the artist would not have omitted them. Neither are they spoken of by Xenophon in his two books upon horsemanship, in which he gives directions for mounting; nor by Julius Pollux, in his *Lexicon*, where all the other articles belonging to horse-furniture are spoken of. The Roman youth, indeed, were taught to vault into their saddles (*Æneid*, xii., 287),—

> ———"Corpora saltu
> Subjiciunt in equos;"

and in their public ways stones were erected, as in Greece also, for such as were incapable of doing so. As another substitute for stirrups, horses in some countries were taught to bend the knee, after the manner of beasts of burden of the East;[2] and in others portable stools were used to assist persons in mounting. This gave birth to the barbarous practice of making captured princes and generals stoop down, that the conqueror might mount his horse from their backs; and in this ignominious manner was the Roman Emperor Valerian treated by the Persian king, Sapor, who outraged humanity by his cruelty. The earliest indisputable mention of stirrups is by Eustathius (the commentator of Homer), about 600 years back, who uses the word *stabia*.

Although the history of the saddle has not exercised the learned world so much as the antiquity of the stirrup, a good deal has been written and said about it. Like all other inventions, it appears to have been suggested by the necessity of making the rider sit easily upon his horse, and some kind of covering, consisting of cloth or leather (skins or hides, perhaps), was placed on the animal's back. These coverings, however, became afterwards extremely costly;[3] they were made to hang down on each side of the horse, and were distinguished among the Greeks and Romans by various names. After they became common, however, it was esteemed more manly to ride without them; and thus we find Varro boasting of having ridden bare-backed when young. Xenophon also reproaches the Persians with having placed as much clothes under their seats on their horses' backs as they had on their beds. It is certain that no coverings to the horses' backs were for a long time used in war; and, according to Cæsar, the old German soldiers despised the cavalry of his country for having recourse to such luxuries. In the time of Alexander Severus the Roman soldiers rode upon very costly coverings, excepting at reviews, when they were dispensed with to show the condition of their horses. But we should imagine we must look to later times for the costly trappings of the horse. In his description of the city of Constantinople, the author of the *Letters of the Turkish Spy* says,—"The next thing worthy of observation is the Serayan, or house of equipages, where are all sorts of trappings for horses, especially saddles of immense cost and admirable workmanship. There cannot be a more agreeable sight, to such as take pleasure in horses and riding, than to see 4000 men here daily at work in their shops, each striving to excel the rest in the curiosity of his artifice. You shall see one busy in spangling a saddle with great oriental pearls and unions intermixed, for some Arabian horse, belonging, perhaps, to the Vizier Azem; another fitting a curb or bit of the purest gold to a bridle of the most precious Russian leather. Some adorn their trappings with choice Phrygian work; others with diamonds, rubies, and the most costly jewels of the East."

But to return to the history of the saddle, its invention, and general use, the latter a point very difficult to be ascertained. The word *ephippium*, by which the ancient Romans expressed it, being merely derived from the Greek words ἐπὶ, *upon*, ἵππος, *a horse*, leads us to conclude that, by degrees, the covering spoken of was converted into a saddle. The Greek word ἕδρα, used by ancient authors, is believed to have been used to express a saddle, and is more than once used by Xenophon, in his *De Re Equestri;* and Vegetius, who wrote on the veterinary art nearly 400 years B.C., speaks of the saddle-tree. Perhaps the clearest proof of the use of anything approaching to the form of the modern saddle, is the order of Theodosius (see his Code), in the year 385, by which such persons as rode post-horses in their journeys were forbidden to use those which weighed more than sixty pounds; if heavier, they were ordered to be cut to pieces. What would the people of those times have thought if they could have seen one of our Newmarket racing saddles, weighing two and a half pounds, but giving the rider a very comfortable seat. The order here alluded to, doubtless applied to something resembling a saddle, although of rude workmanship, as its weight bespeaks. Every traveller, we may conclude, was provided with his own saddle; and about this time the Latin word *sella* more frequently occurs. In the fifth century, again, we find articles bearing something of this stamp, and made so extravagantly magnificent as to call forth a prohibition by the Emperor Leo I. against any one ornamenting them with pearls or precious stones. The saddle-tree is also mentioned by Sidonius Apollinaris, a Christian writer, who was born A.D. 430; and in the sixth century, the saddles of the cavalry, according to Mauritius, who wrote on the military art, had large coverings of fur; and about this period, the Greek word σελλα (*sella*) is used. It is considered probable, however, that the merit of the invention of saddles may be due to Persia, not merely from the circumstance of Xenophon's mentioning the people of that country as being the first to render the seat on the horse more convenient and easy, by placing more covering on their backs than was common in other parts, but also because the horses of Persia were made choice of for saddle-horses in preference to any others. That the word saddle is derived from the Latin word *sedeo*, to sit, may fairly be presumed. That the proper saddle itself, however, was unknown in England until the reign of Henry VII., we have good reason to believe; and in Ireland, from the absence of any representation of it on their coins, it may be conjectured, not till many years subsequent to that period. The woman's saddle, called by us the side-saddle, first appeared in Richard II.'s time, when his queen rode upon one; but from the pictures of men and women's saddles used in England's early days, we find they were miserable apologies for our modern saddles. Indeed at the present time, Great Britain is the only country in which proper saddles are made. Hunting saddles should have their pannels well beaten and brushed to prevent sore backs; and no sportsman, even if light, should use a short saddle, under sixteen inches from pommel to cantle.

---

[2] See Silius Ital., lib. x., 465.—

> "Inde inclinatus collum, submissus et armos
> De more, inflexis præbebat scandere terga
> Cruribus."

[3] See Virgil, *Æneid* vii., 276; viii., 552; Ovid. *Metam.* lib. viii., 33; also *Livy*, lib. xxxi., cap. 7, who speaks of a man who dressed his horse more elegantly than his wife.

The antiquity of the spur does not appear to have much excited curiosity: but the use of this instrument was known in the very earliest age of which we have any satisfactory history. At least we may presume that it was so, from the Hebrew word signifying horseman (*Pavash*), appearing to be derived from a Hebrew root signifying to *prick* or *spur*. So at least says Buxtorff; and he adds, that the horseman, or spurrer, was so called on this account: *Eques quod equum calcaribus pungat;* and he quotes Aben Ezra in confirmation of his opinion:—*A calcaribus quæ sunt in pedibus ejus.* Spurs occur but seldom on seals, or other antiques, in the eleventh century, but in the thirteenth they are more frequent. As it is necessary that a horse should obey the leg as well as the head, all military and parade horses are ridden in spurs; and, as we have already said, they are very useful to the sportsman in riding across a country, particularly in the act of opening gates; also all race-horses that will bear them are ridden with them, because, should punishment be wanting in a race, it is more easily inflicted by the heel than by the hand; add to which, these horses not only require the jockey's two hands at the same time, but are apt to swerve, or shut up, if struck severely by the whip.

Race-Riding, or Jockeyship.—Race-riding and riding over a country cannot be called sister arts. Indeed the former bears little relation to any other system of horsemanship, because, from the rapidity with which the race-horse gets over the ground, there is neither time nor necessity for a display of the various aids which it is in the horseman's power to afford to his horse in most other cases. Nevertheless, the very refinement of the art, the nice and delicate hand, together with a firm and strong seat, is absolutely essential to a good jockey. Neither is this all. He must possess a stout heart and a clear head.

Something like jockeyship was practised in very early times, the Greeks having introduced it at their celebrated games. In the 33d Olympiad they had their race of full-aged horses. In the 71st Olympiad they instituted that for mares called the Calpe, bearing a resemblance to our Oaks Stakes at Epsom; and an interesting anecdote is handed down to us, relating to this race. A mare, called Aura, the property of one Phidolas, a Corinthian, threw her jockey, but continued her course as if he had kept his seat, increasing her pace at the sound of the trumpet, and, finally, as the story goes, presenting herself before the judges, as if conscious of having won. The Eleans, however, declared her to be the winner, and allowed Phidolas to dedicate a statue to her. In the 131st Olympiad, the race of the πωλος κέλης, or under-aged horses, was established; but with respect to all these races, we are left in obscurity as to the weight the horses carried, as also the distance they ran; and whether or not such matters were regulated by their age, and not at all by their size. It is the general opinion that they were left to the discretion of the judges (the Hellanodicæ, as they were called), who regulated all matters at Olympia, as the members of our Jockey Club do at Newmarket; but, as may be expected from the character of the times, exercising a power over their brother sportsmen, which would not be relished at the present day, although, in some respects, well worthy of imitation. For example, they not only excluded from the games and imposed fines upon such as were convicted of fraudulent or corrupt practices, but inflicted bodily correction upon them besides. But some very interesting facts are the result of the rigid scrutiny of this Elean Jockey Club. Alexander the Great was ambitious of obtaining the Olympic crown, but was objected to as being a Macedonian, the prize he wished to contend for being confined to Grecians. Alexander cleared himself by showing, that although he was a prince of Macedon, he was descended from a family that came originally from Argos; and the Hellanodics allowed him to start, but he did not win. Themistocles objected to Hiero, King of Syracuse, as a tyrant, and proposed that the magnificent pavilion which contained his race-horses should be pulled down. The objection, however, was overruled, and he became a winner; but we do not wonder that in a Grecian assembly the name of tyrant should have been abhorred.

The seat of the jockey is one of peculiar elegance, heightened by the almost universal symmetry of his form or figure, for very few ill-proportioned men are seen in the racing saddle. The good appearance of the jockey is also increased by the neat fit of his clothes; his costume appropriate to his calling; the extreme cleanliness of his person, produced by his necessary attention to it during his preparatory course of exercise; and, though last, not least, his almost affinity with the noble animal we see him mounted upon. But for this he is indebted to Nature—to the relation that the bodies of animals hold to natures altogether external to their own; and it is most happily exemplified in that of a man to his horse, which appear to have been especially formed for each other. But, as a celebrated moral philosopher has observed, "There is throughout the universe a wonderful *proportioning* of one thing to another. The size of animals, of the human animal especially, when considered with respect to other animals, or to the plants which grow around him, is such, as a regard to his conveniency would have pointed out. A giant or a pigmy could not have milked goats, reaped corn, or mowed grass; *could not have rode a horse*, trained a vine, or shorn a sheep, with the same bodily ease as we do, if at all."

Previously to describing the proper seat of the jockey, we will now endeavour to exhibit him in the most likely form to acquire that seat. In height he should be about 5 feet 5 inches. We are aware there are several excellent jockeys under this standard; but they do not look so well on their horses, neither can they be so firm in their seat from want of a better clip, which the firm grasp of a longer thigh gives them. He should be rather long in the fork for his height, and powerful, long arms, and a very quick eye. He should be of a naturally spare habit, to save the expense to his constitution by wasting; but he should have as much muscle in his arms and thighs, as his diminutive form will admit of; in short, to ride some horses at such very light weights, he should be a "pocket Hercules." But there must be nothing like rigidity in his frame. On the contrary, there should be a great degree of pliability about his arms, shoulders, and back-bone, to enable him to be in perfect unison with his horse. He should have very free use of his hands, so as to change his reins from one to the other in a race, and to whip with the left, as well as with the right, when occasion requires it; he should possess much command of temper; and, lastly, he should have the abstinence of a Brahmin, and be able by medicine and hard walking in the sweaters to get off the two stone he gains during the winter, without fever, in about three weeks or a month.

The seat of the jockey may be described in a few words. He should sit well down in his saddle when he walks his horse to the post, with his stirrups of moderate length, so as to enable him to clear his pommel, and have a good resisting power over his horse. No man can make the most of a race-horse with long stirrup leathers, because, when he is going at the top of his speed, he sinks down in his fore quarters, in his stride, to the extent of several inches. It was calculated that Eclipse, naturally a low fore-quartered horse, sank nearly 8 inches. The circumstance, then, of the use of the stirrup, in ancient racing, being unknown, fully accounts for racing on horseback as we now race, being, comparatively with chariot-racing, but little resorted to; and the excellency of a jockey in the Olympic Hippodrome, consisting more in a sort of harlequin feat of jumping from one horse, and vaulting upon another, in a race, than in riding and finishing it, as it is now finished, in a severe trial of speed, bottom, and jockeyship. Indeed, some racers go with their heads so low as to bear up their rider from the saddle whether he will or not, and they would pull him over their heads, if he had not the power of resistance from his stirrups. Much was written by Samuel Chiffney, in a pedantic pamphlet called *Genius Genuine*, on riding the race-horse *with a slack rein*, which system has never been adopted by any jockey but his son on a few occasions. Exclusive of the necessity of restraining a free horse, who would run himself to a stand-still if suffered to do so, or of making "a waiting race," all race-horses feel relieved by a strong pull at their heads, and many will "shut up" at once if their heads are loosed. In our opinion, the hand of a jockey should always be firm, though at times delicate to an extreme; and he should never unsettle his horse by any sudden transition from a slack to a tight, or from a tight to a slack rein. In fact, everything in horsemanship is best done by degrees, but at the same time with a firmness and resolution which a horse well understands; and the hand which, by giving and taking, gains its point with the least force, is the best and most serviceable, as well as most agreeable to a horse. Chiffney always insisted that a horse should be "invited to ease himself an inch at a time," and he certainly proved the truth of his curious slack-rein theory by winning on Knowsely (whom no other jockey could hold in the severest curb) in a plain snaffle at Guildford; and on Eagle at Newmarket.

We will now bring our jockey to the starting post, where the first thing he does is to strip. Having inspected the saddling of his horse, and found everything about him secure, he cocks up his left leg, and is chucked into his saddle by the trainer, who generally wishes him "*luck*" as he performs this office for him. After he has seated himself firmly down in it, and tried the length of his stirrup-leathers, he takes a preliminary canter of about a quarter of a mile; and then walks his horse quietly to the starting post. But his method of starting his horse depends entirely on circumstances. If for a half-mile-race—in which a good start is a great advantage—he catches fast hold of his horse's head, and, if he will not start quickly without, sticks both spurs into his sides as soon as the signal is given, taking his chance of getting his head down into its place when and how he can. If for a two-mile race, or over that distance, he need not be in such a hurry at starting, provided he do not lose too much ground; but all this must in great measure be regulated by his orders, whether to make running or to lie by, and wait. We will, however, put him in all these different situations.

The Half-mile Race, generally straight. Orders, "*To make running*." Having turned his horse round *beyond*, or we should rather say *behind*, the post, he brings him as quietly as he can back to it. On the word being given, he gets him on his legs as soon as he possibly can, dropping his hand to him to enable him to feel his mouth, and endeavours to "steady him." He lets him go perhaps half the distance he has to run with only his head hard held, before he gives him his *first* pull; but this event (the half-mile race) being soon over, there is no time for much speculation, and the pull must be but a short one. He then runs up to his horses again; lives with them to the end and wins, if he can, without a second pull; but if he finds other horses too near to be pleasant, or, in other words, appearing to be as good as his own, he takes a second pull within the last 100 or 200 yards, when he "comes" again and wins. The same directions hold good in a mile race, with the exception that the jockey need not be quite so much on the *qui vive* at starting, and his pulls may be longer, and the last nearer home.

The Half-mile Race. Orders, "*To wait*." In this case the jockey gets well away with his horses, but never more than a length or two behind any of them, as more than that distance is difficult to make up in so short a race. Within 150, or perhaps only 30 yards, from home, he makes his effort, or it may be that he never gets up till the last stride, and wins, as the saying is, a head on the post.

The Mile Race. Orders, "*To wait*." The jockey may start last of all if he like, but he must not lose much ground. However good judge a jockey may be of *pace*, it is a fault to lie far out of his ground. Let him then also lie well with his horses all the way, creeping up to them inch by inch, and not quit them to win till he feels certain he has the race in his hand; that is, till he sees that the other horses have run themselves out. His orders to wait have been given him from the supposition or knowledge that speed, not stoutness, was the best of his horse, and, consequently, that if he had made the running or "play," he would not have run home.

The Two-mile Race. Orders, "*To make running*." Nothing, next to the struggle of the last 150 yards between two horses very nearly equal, called on the turf "the set-to," is so difficult in racing horsemanship, as making running or "play" by a jockey, solely for the benefit of the horse he himself is riding. In other words, it is a great accomplishment in a jockey to be a superior judge of *pace*, that is, of not merely the pace he himself is going, but how that pace affects the other horses in the race. And this task is difficult with idle or lurching horses, which, when leading, require urging by the hand or leg every yard they go. In this case the jockey works hard to keep his horse going. He has to use his hands, arms, legs, and feet, and occasionally to turn his head round, with all his limbs in action, and yet not disturb his horse's action. The upshot is, if his horse answers the opinion entertained of him, by cutting up his competitors by severe "play," he wins his race, and has the character of being a stout, honest horse. One of the greatest triumphs of a jockey is to get in front and ride what is styled a waiting race in front, when he dreads the effect of a severe pace from end to end on his horse.

The Two-mile Race. Orders, "*To wait*." In this case the jockey goes off at a steady pace, with a good hold of his horse's head, as near to the other horses as he likes, but not attempting to go in front. Thus he continues in his place to within a certain distance from home, probably specified in his orders, when he brings out his horse, challenges the leaders one after another, and wins, if his horse be good enough. This style of race requires immense judgment, as, if a jockey lays too much out of his ground at starting, he would never be able to catch his opponents in time to get a pull at his own horse.

The duty of a jockey is to win his race if possible, and not to do more than win it; and a very clever one, if he is opposed to another of less science in a finish, will "gammon" he is beat; and then if his opponent eases his horse or becomes at all careless, he catches him with a tremendous rush on the post. The "Chiffney rush" has passed into a proverb; and Job Marson's victorious one on "Nutwith," for the St Leger of 1843 has also been greatly famed. Perhaps one of the finest specimens of jockey science was displayed by those celebrated Newmarket riders, Robinson and Chiffney, on "Camarine" and "Rowton" in the Ascot cup of 1832. Buckle was also very great in the saddle, especially when he had an idle horse to "set-to" on; but, although these *artistes* have quitted the scene, and Frank Butler was taken from it in his very zenith, we have still some first-rate talent left. Amongst the elder ones may be specially reckoned Flatman (better known as "Nat") Rogers, J. Marson, Templeman, Marlow, Bartholomew, and Alfred Day; whilst Wells, Aldcroft, Charlton, Ashmall, J. Mann, J. Osborne, G. Oates, Quinton, and Fordham, are at the very head of the younger generation, who have splendid chances of early distinction in these handicap days.

All good jockeys avoid the use of the whip as much as possible. When a race-horse is in the fullest exercise of his powers and doing his best, it is unnecessary, for it cannot make him do more, and it often has the effect of making him shut up at once. One of the gamest horses that has run during the last twenty years flinched at the finish of a severe race at Doncaster in consequence of a chance blow from his jockey's whip on the tail. The spur, properly used, is a much better instrument for increasing the speed of a horse, although there are times when the application of the whip, or the mere act of flourishing it in the hand, is eminently serviceable to the jockey; we mean when his horse hangs to one side of the course or the other, or towards other horses in the race, or exhibits symptoms of running out of the course, or bolting. A jockey ought to be able to use his whip with vigour when necessary, and (though this do not often happen) with his left hand as well as with his right, in case of his losing what is called the whip-hand, when he cannot use his right. The nature and form of the race-course also will call for accurate knowledge of the peculiar action of his horse.

Our remarks on the art of race-riding may be concluded by stating the manner in which horses of various tempers, dispositions, and capabilities, are to be ridden, with the best chance of being made the most of. Nine racers in ten are free-going ones, if not hard pullers. On one of this description the great art of the jockey is to economize his powers according to the length he has to go, as also the weight he is carrying, so as not to let him over-pace himself, and have little or nothing left in him at the finish. If other horses make running, this can only be done by his sitting perfectly still in his seat, dropping his hands, and having fast hold of his horse's head. The less he interferes with his mouth the better; and if he likes to be well up with the other horses, he is better there, supposing him not to be a regular jade, than pulled at, to be kept back. Temper is a great thing in this case—we mean in the jockey; for a hasty horse and a hasty rider are sure to disgrace themselves. Every unnecessary movement in the one is instantly responded to by the other, who becomes flurried, and pulls more determinedly than he did before.

The lazy, sluggish, or "craving" horse, as trainers call him, requires riding from end to end of his race. By this we mean, that although the body of his jockey should not move, he is often obliged to raise his hands off his horse's withers, to shake him now and then; as well as to use his feet to urge him to a better pace, or even to keep him at the one he is going. Indeed, he will sometimes require a blow with the whip, or at least to be very much roused, to make him extend his stride towards the finish of his race. This is the sort of horse that used to distinguish himself in four-mile races at Newmarket, and was, of course, not thought the worse of by his owner for taking so much riding to make him do his best.

But the most ticklish and difficult horse, next to the determined restive one, or bolter, is what is known by the appellation of the "Flighty Horse," one which is as difficult to train as he is to ride, being delicate in constitution, of extremely irritable temper, and very easily alarmed. The jockey that has to ride a horse of this description, should have a temper the very reverse of his, and a hand as delicate as a woman's. He must also indulge him in every way save one, which is, in not allowing him to overpace himself. But here, also, he must be careful; for this horse will neither bear to be pulled nor hustled, but must be let to go nearly in his own way, with the exception of being kept well together by a steady hold of his head. If challenged in the race, he must accept the challenge, and come out of the conflict as well as he can.

Jockeys, of whom there are about 180 in the United Kingdom, riding all weights from 8 st. 7 lb. to 4 st. 7 lb., delight in finding themselves on a fine-tempered racer; such as Zinganee was in the year 1829, and of which year he was considered the best horse. In a plain snaffle bridle, without even a martingal, as he was ridden, and with an obedient mouth, it is a pleasing instead of an irksome task. A horse of this description is easily held, is kind at his turns, in fact, will nearly make them of his own accord; will either wait or make play, as his rider's orders may be; and when called upon to challenge, is ready to do his best. More than this, he is always going within himself, because he is obedient to his jockey's hand; and his temper is at least equal to 4 lb. weight in his favour.

We now conclude our remarks on jockeyship with a short description of the last 400 yards of a race; the leading horses lying close together, and all well up. The set-to is about to begin. But before the jockey does this, he alters his position in his saddle. He has been previously standing up in his stirrups, with his body leaning forward over the horse's withers, and his hands down, somewhat below them. He now seats himself firmly down in his saddle, and, raising his hands off his withers, first gives his horse an easy pull, and then the set-to begins. He now moves his hands, as if describing a circle, by way of rousing his horse; and although he does not quite slacken his reins, he allows him to reach with his head, as a distressed horse will always do, and which is technically termed "throwing him in." Then comes the last resource. If he finds, when within a few yards of home, that he cannot win by these means, and that his horse appears to sink in the rally, he pricks him a few times with his spurs; gets his whip up in his right hand, giving a good pull with his left, and uses it as occasion may require.

Steeple-Chase Racing.—A new system of racing jockeyship has come into fashion in Great Britain and Ireland within the last forty years, which, however daring, we know not how to commend. We think it an unreasonable demand on the horse, to require him to go at a racing pace over rough and soft ground, with the addition of having too often a country selected for him to run across, which, if it is not deemed difficult, is dotted with artificial fences and brooks. Several human lives have already been sacrificed, and, we are sorry to say, several horses have died from broken backs in steeple-chases. The four miles and a quarter of the Liverpool course is often covered in little more than ten minutes, by horses, who have no claim to rank with Grimaldi, Vyvian, Lottery, and Discount, the whilom heroes of this amusement; which is at a low ebb now to what it was when Captain Ross and "The Squire" met on Clinker and Clasher for their great matches in Leicestershire.

Qualifications for a Steeple-Chase Rider.—These are exactly what are wanting in a very fast run over a stiffly inclosed country with fox-hounds; namely, a fine bridle-hand, a steady seat, a cool head, undaunted courage, and above all things, great quickness, and very prompt decision. But the steeple-chase jockey has one evil to guard against, which the racing jockey is, comparatively, but little subject to, and this is a fall. The best preventive of it is keeping a horse well together, and making him go in a collected form at his fences, as well as over rough ground. But, at the same time, he must not overpace his horse, or he will not be able to rise at his fences when he gets to them. And here lies the great difficulty after all, as far as the horse is concerned. He must go, at least he is called upon to go, at a much quicker rate than he can reasonably be expected to maintain, for any considerable length of time, without becoming distressed, because his competitors in the race are also doing so, and he will be left behind, to a certainty, if his rider do not endeavour to make him keep with them. That horse, then, has the best chance to win which, barring a fall, is the stoutest runner and surest fencer, and whose rider is good enough, and strong enough, to give him all the assistance he requires, at least as much as a rider can give him, to enable him to struggle through his difficulties to the end. But there is one quality in a horse, especially calculated for steeple-chase racing, and that is *quickness.* After fencing some are on their legs again, and get away instantly, as soon as they alight on the ground, be the fence ever so large, whilst others dwell for some time after landing, previously to their recovering their equilibrium, and so lose time. It is evident, then, that a quick horse, with a quick man on his back, is best adapted to a steeple-chase; and would beat another, supposing leaping and other qualifications, this excepted, to be equal, which could give him half a stone weight over the Beacon Course, and beat him.

It is no great compliment to this species of horsemanship to show its origin, which is thus given in a work called *The Gentleman's Recreation*, written nearly 200 years back: "But before I enter upon the subject proposed" (training of horses), says the author, "I think it convenient to tell you the way our ancestors had of making their matches, and our modern way of deciding wagers; first, then, the old way of trial was, by running so many train scents after hounds, this being found not so uncertain and more durable than hare-hunting, and the advantage consisted in having the trains laid on earth most suitable to the nature of the horses. Now others choose to hunt the hare till such an hour prefixed, and then to run the *wild-goose chase*, which, because it is not known to all huntsmen, I shall explain the use and manner of it. The wild-goose chase received its name from the manner of the flight which is made by wild-geese, which is generally one after another, so that two horses, after the running of twelve score yards, had liberty, which horse (qr. rider?) soever could get the leading, to ride what ground he pleased, the hindmost horse being bound to follow him within a certain distance, agreed on by articles, or else to be whipt up by the tryers or judges which rode by, and whichever horse could distance the other, won the match. But this chase was found by experience so inhumane, and so destructive to horses, especially when two *good* horses were matched; for neither being able to distance the other, till ready both to sink under their riders through weakness, oftentimes the match was fair to be drawn, and left undecided, *though both horses were quite spoiled.* This brought them to run train scents, which was afterwards changed to three heats, and a straight course." Our readers will acknowledge the resemblance between the modern steeple and the ancient wild-goose chase; and we trust that ere long, the example of our ancestors will be followed, and the man who is capable of exhibiting his horsemanship in a modern steeple-chase, will reserve his prowess for a better if not a nobler cause.

(C. A.) (W. H. L—Y.)

HORSE-POWER, a unit of force introduced by Watt to enable him to determine what size of engine to send to his customers to supersede the number of horses which the new power was to replace. Watt ascertained at one of the London breweries that the average force exerted by the strongest horse was sufficient to raise 33,000 lbs. one foot high in a minute; thus, an engine of 200 horse-power would be a force equal to that of 200 horses, each lifting 33,000 lbs. one foot high per minute.

Watt had two methods of estimating and comparing his engines—viz., by the *power* and by the *duty*. By the power is meant the quantity of work which an engine can effect in a given time; by the duty is meant the quantity of work which it can effect by a given expenditure of fuel. Now, it is evident that without any change in the size of an engine, but simply by increasing the pressure of the steam, the power of an engine may be greatly increased—that is, the load remaining constant, the speed of the piston may be increased, the number of strokes may be increased, and, consequently, the work done per minute will be increased also. Hence it is difficult to apply a limit to the power obtainable from the smallest cylinder, provided the boiler be large enough to evaporate the increased quantity of water, and strong enough to resist the increased bursting pressure. In fact, no size of cylinder can be reckoned as having a particular power, since the power depends not on size but on strength. Nevertheless, in modern engineering the term *horse-power* refers rather to the size of the cylinder than to the power exerted, and the value of the unit has undergone many changes; so that in a modern engine, a horse-power may imply 52,000 lbs., or 60,000 lbs., or 66,000 lbs., raised one foot high per minute. The plan now adopted for ascertaining the performances of different engines is by an instrument called an *indicator*. This consists of a small cylinder fitted with a piston, which is pressed down by a spring. By the height to which this piston rises against the spring the steam pressure within the cylinder of the engine is indicated; and the number of lbs. pressure on the square inch multiplied into the number of square inches in the area of the cylinder, and by the number of feet travelled through by the piston per minute, gives the impelling power: deduct in large engines about $\frac{1}{10}$th for friction, and the remainder is the efficient moving power, which, divided by 33,000, gives the actual horse-power. See STEAM. (C. T.)

HORSHAM, a parliamentary borough and market-town of Sussex, on a branch of the Arun, 37 miles S.S.W. of London. It is a borough by prescription, and returned two members to parliament previous to the Reform Act, by which it was deprived of one of its representatives. The borough is governed by a steward and two bailiffs. Horsham consists of two streets, crossing each other at right angles, one of them being adorned with rows of trees. The town-hall is a handsome Gothic building. St Mary's church is a spacious and elegant edifice in the early English style, with a tower surmounted by a lofty spire. The grammar school, founded in 1532, is now in a very flourishing state; the present rental of its endowment is upwards of L.400 per annum. There are no manufactures of importance; but a considerable trade is carried on with the surrounding country. Market-days, Monday and Saturday. Pop. (1851) 5947.

HORSLEY, Samuel, a very learned prelate of the Church of England, the son of the Rev. John Horsley, for many years clerk in orders at St Martin's in the Fields, and afterwards rector of Thorley in Hertfordshire, was born at his father's residence in St Martin's Churchyard in October 1733. He received his early education from his father, and was entered at Trinity-hall, Cambridge, where he applied himself to the study of mathematics, and the writings of the ancient and modern divines and logicians. Why he took no degree in arts cannot now be ascertained. We find, however, that in 1758 he took that of bachelor of laws, and became his father's curate at Newington, which living he succeeded to the following year, and held until his elevation to the episcopal bench in 1793, as Bishop of Rochester.

In April 1767 he was elected a fellow of the Royal Society, of which he continued for many years an active member; and about the same time he published a pamphlet on the *Power of God*, "deduced from the computable instantaneous productions of it in the solar system." This he allows to be a "very singular and whimsical speculation." In 1768 he went to Christ-Church, Oxford, as private tutor to Heneage Earl of Aylesbury, then Lord Guernsey. In 1770, his first mathematical publication, *Apollonii Pergæi Inclinationum libri duo*, was elegantly printed at the Clarendon press. This work, though severely criticized at the time, and in reality not distinguished by any peculiar felicity of restoration, does not appear to have injured his rising reputation; for in November 1773 he was appointed secretary to the Royal Society, and in 1774 he had the degree of doctor of civil law conferred on him at Oxford, and was presented by the Earl of Aylesbury to the rectory of Aldbury, in Surrey, along with which he obtained a dispensation to hold that of Newington. The same year he published *Remarks on the Observations made in the Voyage towards the North Pole, for determining the acceleration of the Pendulum in Lat.* 79. 51.

Dr Horsley having long meditated a complete edition of the works of Sir Isaac Newton, issued in 1776 proposals for printing it by subscription, in five volumes 4to; but the commencement of the undertaking was delayed by severe domestic affliction, nor was it completed until 1785. In the meanwhile his diligence and proficiency in science attracted the notice of Dr Lowth, who, on his promotion to the see of London in 1777, appointed Dr Horsley his domestic chaplain, collated him to a prebend in St Paul's Cathedral, and procured for him the situation, which had been held by his father. of clerk in orders at St Martin's in the Fields. In 1778, during the controversy between Dr Priestley, Dr Price, and others, on the subject of materialism and philosophical necessity, Dr Horsley published a sermon on *Providence and Free Agency*, in which he attempted to draw a distinction between the philosophical necessity of the moderns and the predestination of their ancestors. This discourse was evidently directed against the writings of Dr Priestley, but the latter did not take any immediate notice of the attack. In 1779 Dr Horsley resigned Aldbury, and in 1780 was presented to the living of Thorley, which he held by dispensation along with that of Newington. In 1783 he became deeply involved in a dispute with some members of the Royal Society, which ended in his withdrawing himself from that learned body.

Dr Horsley was now about to engage in that celebrated controversy with Dr Priestley, which was conducted on both sides in the fiercest spirit of polemical contention, but on that of Horsley with superior learning and ability. In 1782 Dr Priestley published a work in two volumes 8vo, entitled *A History of the Corruptions of Christianity;* at the head of which he placed both the Catholic doctrine of Christ's divinity, and the Arian doctrine of his pre-existence, in a nature far superior to the human, at the same time representing the Socinian doctrine of his mere humanity as the unanimous faith of the first Christians. Dr Horsley, conceiving that the best antidote to the poison contained in this work would be to destroy the credit of the writer and the authority of his name, made its imperfections, moral as well as literary, the subject of review in a charge delivered to the clergy of the archdeaconry of St Albans, at a deputation held on the 22d of May 1783. The specimens produced as evidence of the imperfections of the work and the incompetency of the author, may be reduced to six classes. First, instances of reasoning in a circle; second, instances of quotations misapplied through ignorance of the subject; third, instances of testimonies perverted through artful and forced constructions; fourth, instances of passages in the Greek fathers, misinterpreted through ignorance of the Greek language; fifth, instances of passages misinterpreted through ignorance of the Platonic philosophy; and, sixth, instances of ignorance of the phraseology of the earliest ecclesiastical writers. Dr Horsley concludes his charge by observing, "I feel no satisfaction in detecting the weakness of this learned writer's argument, but what arises from the consciousness that it is the discharge of some part of the duty which I owe to the Church of God." This vigorous and systematic attack staggered the admirers of Dr Priestley; but he himself felt none of the apprehension with which they were seized. His reply was entitled, *Letters to Dr Horsley, in answer to his Animadversions on the History of the Corruptions of Christianity, with additional evidence that the primitive Christian Church was Unitarian*, 1783, in 8vo. To this production, in which there are more errors of haste and infirmities of argument than could have been expected from one who had so much at stake, Dr Horsley replied in the same epistolary form, by *Letters from the Archdeacon of St Alban's, in reply to Dr Priestley.* Dr Priestley, in his *Letters*, had attempted to draw his adversary into a controversy respecting the divinity of Jesus Christ; but the latter, knowing that question to have been long since exhausted, defended his own argument, and confined himself to the collection of proofs from Dr Priestley's publications of his inability to throw any light upon the subject.

Dr Priestley, finding that his *Letters* had failed to produce the expected impression, now lost all temper; and in a second set of letters to the Archdeacon of St Alban's, which appeared in the autumn of 1784, threw aside all profession of personal regard, or even of ordinary civility. The charge of incompetency and ignorance was warmly retorted, and "the incorrigible dignitary" was charged with manifest misrepresentation of his adversary's argument; with injustice to the character of Origen, whose veracity he had called in question; and with the grossest perversion of ancient history. In a word, he was stigmatized as a "falsifier of history, and a defamer of the character of the dead." Regardless of this reproach, Dr Horsley remained silent for eighteen months. A sermon on the Incarnation, preached upon the feast of the Nativity in 1785, formed the prelude to the renewal of the contest on his part, and was, early in the ensuing spring, followed by *Remarks on Dr Priestley's Second Letters to the Archdeacon of St Alban's, with Proofs of certain Facts asserted by the Archdeacon.* This tract consists of two parts; one containing new specimens of Dr Priestley's temerity in assertion; and the other defending the attack upon Origen, and proving the existence of a body of Christians at Ælia after the time of Hadrian, which was the fact upon which the Archdeacon's historical fidelity had been so loudly arraigned by Dr Priestley. With this publication Dr Horsley had intended that the controversy on his part should close; but having been induced to collect and republish what he had written (in one vol. 8vo, 1789), this led to a second perusal of Dr Priestley's *Letters*, which produced not only many important notes, but some disquisitions of considerable length; and as the *Remarks on Dr Priestley's Second Letters* had elicited a third set, in which he endeavoured to support the veracity of Origen, and to maintain his position respecting the orthodox Hebrews of the church at Ælia, these are replied to partly in the notes, and partly also in two of the disquisitions.

The reputation which Dr Horsley had now acquired, recommended him to the patronage of Lord Chancellor Thurlow, who presented him to a prebendal stall in the cathedral of Gloucester; and, by the interest of the same eminent person, he was, in 1788, promoted to the see of St David's. As a bishop, his conduct was exemplary and praiseworthy; in this character he fully answered the high expectations of eminent usefulness, which his elevation to the mitre had so generally raised. In his diocese, he carried through a general system of reform, regulated the condition of the clergy, introduced greater strictness with respect to candidates for admission into holy orders, preached frequently in the parish churches, and acted with Christian liberality towards the poor. Bishop Horsley's first charge to the clergy of St David's was delivered in 1790, and deservedly admired, as was also his animated speech in the House of Lords 31st May 1791, on the subject of the Catholic Bill. These effective displays are understood to have occasioned his subsequent promotion to the bishopric of Rochester and the deanery of Westminster, upon which he resigned the living of Newington.

During the agitating period between 1793 and the close of the century, Bishop Horsley ranged himself on the side of the government, and with great zeal and warmth opposed the enemies of the constitution, and the professors of democratic principles, under which categories were then included all those who sought for reform in the representation of the people as a guarantee for the removal of abuses, and the progressive improvement of our institutions, ecclesiastical as well as civil. As a senator, his talents and activity necessarily gave him weight; and there were few discussions of importance in which he did not take part. He was not, however, an every-day speaker, nor desirous of protracting the debate, unless he had something original or important to communicate. In 1802, he was translated to the bishopric of St Asaph, and resigned the deanery of Westminster. Until 1806, his vigour of body and mind remained unimpared. In the month of July of that year he went to his diocese, and after a residence of two months intended to visit his patron Lord Thurlow at Brighton, where he arrived on the 20th of September, after learning on the road that his noble friend was no more. On the 30th, he became affected with a complaint in the bowels, which, slight at first, soon terminated in mortification, and on the 4th of October proved fatal. He died in the seventy-third year of his age.

Bishop Horsley was a hard student all his life. His active mind was ever directed to some pursuit. He was an acute and original thinker, with a powerful intellect. He was proficient in languages and Scripture criticism, and thus well fitted for controversy. He was naturally warm and uncompromising, and considering the agitated period in which he lived, whether as to church or state, it is no more wonderful that he exhibited at times the heats and asperities of controversy, than it is that his opponents did the same. Though a high churchman, he possessed more true liberality, and understood better the broad principles of practical toleration, than many of his clamorous opponents. His sermons display vigour, depth, precision, originality, and judgment. His patient research and extensive erudition often enable him to render easy a difficult subject.

Besides the works already mentioned, Bishop Horsley was the author of the following, viz.,—1. On the Properties of the Greek and Latin Languages, 1796, in 8vo; 2. On the Achronical Rising of the Pleiades, appended to Dr Vincent's *Voyage of Nearchus*, 1797; 3. A Circular Letter to the Diocese of Rochester, on the Scarcity of Corn, 1796; 4. Another Circular Letter to that Diocese on the Defence of the Kingdom, 1798; 5. Critical Disquisitions on the 18th Chapter of Isaiah, 1799, in 4to; 6. Hosea translated from the Hebrew, with Notes explanatory and critical, 1801, in 4to; 7. Elementary Treatises on the fundamental principles of Practical Mathematics, for the use of Students, 1801, in 8vo. Since his death have appeared,—1. Sermons, 1810 and 1812, in three vols. 8vo; 2. Tracts in controversy with Dr Priestley, upon the historical question of the belief of the first ages in the Divinity of Jesus Christ, revised and augmented by the author, with an Appendix by his Son, 1812, in 8vo; 3. The Speeches in Parliament of Samuel Horsley, 1813; and, 4. The Charges delivered at his several visitations of the dioceses of St David's, Rochester, and St Asaph, 1813, in 8vo.—(Chalmer's *Biog. Dict.*, art. HORSLEY; *Edinburgh Review*, vol. xvii. p. 465, 468.) (J. B—E.)

HORTENSIUS, QUINTUS, one of the greatest orators of Rome, was born of an equestrian family, B.C. 114. At the early age of nineteen he appeared in the forum, and distinguished himself so as to attract the notice of the consuls Scævola and Crassus, the former the greatest jurist, and the latter the greatest orator of that day. Attaching himself to the Sullane faction, he found ample scope for his professional services in defending the numerous adherents of that party who were tried for misgovernment or extortion in their provinces. His success in these trials was so great that till the appearance of Cicero he was called the "rex judiciorum;" but Hortensius was never very scrupulous as to the means he took to secure a verdict in favour of his clients. Extant evidence proves that he was only too well acquainted with all the arts of bribery, and that he often practised them in flagrant defiance of justice. Though both at the bar, as well as in politics, Hortensius was always opposed to Cicero, yet in private life the rivals seem to have been on terms of intimacy, if not of friendship, with each other. On Cicero's side, however, the friendship seems never to have been wholly cordial. Perhaps friendship was impossible to a man of so suspicious and irritable a temper as he. At all events, when Cicero was obliged to leave Rome after failing in his impeachment of Clodius, he suspected that Hortensius had a share in procuring his exile, and censured this supposed duplicity in no measured terms. All the efforts of Atticus to undeceive him failed, and it was only after his return that he acknowledged the groundlessness of his suspicions. For ten years before his death Hortensius had retired from political life, and confined himself to his practice as an advocate. He had gone through the usual career of public office; and had distinguished himself by the almost unparalleled splendour of the games which he celebrated when quæstor, ædile, and prætor. His luxurious tastes and habits remained with him to the last; and as his professional gains were enormous, he had ample means of gratifying them. He lived in a style not inferior to Lucullus; and his villas at Bauli, Tusculum, and Laurentum were proverbially magnificent. He died B.C. 50, two years before the final overthrow of the Republic. Cicero remarked it as of a piece with Hortensius' usual good luck that he had been spared the pain of seeing this catastrophe completed. He is mentioned by Cicero and Quinctilian as the author of *Orations* and *Annals*, which have all perished. He also wrote love songs, some of them not very decent. Nearly all that is known of Hortensius is gathered from the works of his friend and rival Cicero. An analysis of his genius as an orator is given by Cicero in his *Brutus*, and in the opening chapters of the *De Claris Oratoribus*.

HORTICULTURE.

Introduction.

Horticulture is that branch of rural economy which consists in the formation and culture of Gardens. It is the science of the cultivation of culinary vegetables, fruits, and flowers. On one side it is allied to Agriculture, from which, however, it is distinguished by the nature of its products, and by the smaller extent and greater complexity of its operations; on the other side, in its processes of embellishment, it approaches the arts of the Landscape Gardener and the Forester. For these latter departments of rural art, considered as distinct from Horticulture, see Landscape Gardening.

Like other arts, Horticulture borrows its principles from the general sciences. To Botany it is indebted for the facts and theories of vegetable physiology; to Chemistry for assistance in reference to soils, manures, and artificial heat; and to Meteorology for a knowledge of many circumstances which very materially affect the labours of the gardener. On these subjects, with which the philosophical horticulturist will not fail to make himself familiar, we refer to the various scientific articles in this Encyclopædia. It is very desirable that such information should be extensively diffused among *practical* men; as it is only from this quarter that much improvement, in our present state of knowledge, can be expected. Gardening has, until lately, too generally been practised, and treated as an empirical art. Those who were minutely conversant with its numerous manipulations were generally deficient in that intellectual training necessary to enable them to wield general principles with effect. This useful art is based on the imitation of Nature; for although the processes of nature may be in some measure originated—as when a seed is inserted in the ground, or modified—as in the artificial training of fruit-trees, they can neither be entirely controlled nor counteracted. The principle of vegetable life will not suffer interference beyond a certain point, and our theoretical views should be so directed as to interfere with this principle as little as possible. Accordingly the rapid advancement of Horticulture in recent times may be traced to the strictly scientific basis on which it has been placed, and the close adherence to the laws of vegetable physiology which has supplanted the prejudices of former days. The writings of De Candolle, Dutrochet, Bonnet, Papin, Sennebier, Duhamel, Mariotte, Liebig, Saussure; and those of our own countrymen, Keith, Knight, Priestley, Lindley, and Balfour, have greatly contributed to this result.

Gardening was undoubtedly among the first of the arts to which the attention of man was directed. If we would ascend into remote antiquity, we can have recourse only to conjecture, for although, in the Sacred Writings, and in the earliest profane authors, allusions to gardens occur, little is told us either of their productions or their culture. At the close of the Roman commonwealth, the catalogue of fruits had become considerable, the principles of grafting and pruning were understood and practised, and shortly afterwards, even artificial heat seems to have been partially employed. With the decline of the empire, horticulture also declined or became stationary; but at the revival of learning, it arose from the slumber of the dark ages, encumbered, it is true, by the dreams of the alchymists, the restrictions of unlucky days, and the imaginary effects of lunar influence. From these fetters it was ere long emancipated by the diffusion of knowledge, and it has hitherto kept pace with the general improvement of society. Modified by climate and other circumstances in different countries, its advancement has been various; but nowhere has it made greater progress than amongst ourselves. Introduced into England at an early period, gardening made great progress in the reign of Henry VIII. and his immediate successors, and met with considerable attention during the reigns of the Stuarts. In the first half of the eighteenth century, Miller, Switzer, and others, laboured with success in improving the operations, and unfolding the principles, of the art; and these were succeeded by Abercrombie, Speechly, and a host of writers, who added greatly to our stores of knowledge. In 1805 was established the Horticultural Society of London, which was soon followed by the institution of the Caledonian Horticultural Society at Edinburgh; and in their train have sprung up a multitude of provincial gardening societies, all of which have given an impulse to the public mind, and stimulated the exertions of individuals. Experimental gardens have been formed, in which, amongst other things, the important work of distinguishing and classifying the numerous varieties of our hardy fruits has been zealously prosecuted. The mass of information now collected is immense, and the labour expended in its diffusion unwearied. Judging from the literature of the day, we shall scarcely find any art, however nationally important, which receives more attention, or on which the liberality of the wealthy is more abundantly bestowed. The public nursery-gardens, too, both at London and elsewhere, establishments intimately connected with our subject, and which, in a manufacturing nation, are not the least wonderful amongst the applications of skill and capital, prove the extent and perfection to which gardening has advanced.

We shall, in what follows, confine our attention almost exclusively to the horticulture of Great Britain, and endeavour to give such an exhibition of its practice as may suit the middle districts of the island. It would be unprofitable to describe all the methods of culture in practice; and we shall therefore notice such only as are deemed the best.

The subject naturally divides itself into the Fruit, the Kitchen, and the Flower Garden; but as the first two generally occupy the same locality, or are intermingled with each other, we shall, to some extent, take them together. Then will follow the Flower Garden; Conservatory and Plant-houses; and by way of conclusion to the whole, a short Calendar.

Before proceeding to these departments, it may prevent unnecessary repetitions, to offer a few brief remarks on the general principles of vegetable origin and existence.

The first principles of vegetation are those which regulate Propagation and Growth. All plants are propagated by Seed, Cuttings, Layering, Budding, or Grafting. Imported seeds should be sown as soon as they are received, unless in the case of those that vegetate speedily, which should be sown neither late in autumn, nor early in winter, as in the event of their vegetating during the dark months the young plants would likely perish. Hard seeds, and such as do not vegetate rapidly, may be committed to the soil at those periods when it is calculated their growth will commence.

Propagation by Seed.—Germination, or the sprouting of the seed, depends on the presence of moisture and a due amount of heat and air. No seed will germinate at 32° Fahr., nor if enclosed in hermetically sealed vessels, nor even if too deeply covered with soil. A full account of the requisites for germination, and of the chemical changes which occur, is given under the article BOTANY, Part I. § iv. 2.

Propagation by Cuttings of the Wood, the mode next in importance and general use, consists in originating new individuals by means of portions of the parent plant. Sometimes pieces of the roots are employed, but more generally portions either of the young wood of the current season of growth, as in the case of Heaths; or portions of the ripened wood of the previous season, as in Currants and Gooseberries; or occasionally single eyes or buds, as in the Vine; or truncheons of the stem and older branches, as in the Willow and Mulberry; or the leaf, as in Gloxinia; or any part of the plant, as in the majority of Succulents.

The immediate cause of the formation of roots is as yet unknown, but the remote cause is conjectured by Lindley to be the elaboration of organisable matter by the leaves, for, as he observes, "there can be no doubt that the development of roots is much assisted by the descending sap. When a ring of bark is removed from a branch, if the wound is wrapped in damp moss, roots will invariably push from the upper lip of the wound, while the lower will produce none, a fact so well known, that it has been one of the causes of an opinion, that roots are bundles of wood liberated from the continual perpendicular system, and that the wood itself is nothing but a mass of roots formed by the leaves and buds." Roots, for the most part, are formed in the dark, and hence the seed, the cutting, and the layer, are buried more or less under ground.

Heat has a very considerable effect on the formation of roots in cuttings, and hence the most successful mode is to place the cuttings in a mild bottom heat. Many hardy plants which strike roots when their cuttings are planted in the open soil, would do so much sooner if placed in heat. Some hard-wooded trees, as the common White Thorn, refuse to root when their cuttings are planted in the natural soil, yet they will do so readily if placed in a bottom heat. We must first obtain roots to our cuttings before leaves need be looked for, and to obtain this the temperature of the soil in which the cuttings are placed, must be several degrees higher than that of the atmosphere. It is an invariable rule throughout plant culture that the root action shall be in advance of that of the leaves. Deciduous trees and shrubs succeed best when the cuttings are planted early in autumn, while the soil retains the solar heat absorbed during summer. Evergreens propagate by these means best, when the cuttings are planted during April or May, August or September. Greenhouse and stove plants are propagated in this way during the spring and summer months. The great object to be attained is to get them established with active roots before the approach of winter.

The following, from "Lindley's Theory of Horticulture," contains the main essentials required in this process of propagation. "What is demanded when cuttings or plants are to be struck, is a due adjustment of heat, light, and moisture. The first stimulates the vital processes, the second causes the formation of matter, out of which roots and leaves are to be organised; the third is at once a vehicle for the food required by the cutting, and a part of it. The great difficulty is to know how to adjust these agents.

"If the heat is too high, organs are formed faster than they can be solidified, if too low, decay comes on before the reproductive forces can be put in action. When light is too powerful, the fluid contents of the cutting are lost faster than they can be supplied; when too feeble there is not a sufficiently quick formation of organisable matter with which to construct the new roots and leaves. If water is deficient, the cutting is starved; if over-abundant, it rots. It is, then, the adjustment of these forces to the peculiar nature of the cutting to be acted upon that constitutes the art of propagation. It is this which theory cannot supply, but which depends upon skill and experience. If any part of the operations of cultivation can be called empirical, it is this. And yet the operator is not without rules to guide him in this adjustment; the misfortune is that they are too general. The softer the cutting, the quicker must be the excitement and the application of the formative process. The more hard and woody the cutting is, the slower will be the operation."

Light and moisture have also a considerable effect on the constitution of the cutting. When intense light is allowed to strike on a cutting before its roots are formed, and especially if the cutting be a soft-wooded one, undue transpiration is excited; this transpiration therefore must be modified by partial shading, and the loss of sap made up for by keeping the atmosphere and soil moist. These precautions must be continued until the roots are formed, when they will imbibe fluid from the soil as fast as the sun dries it off from the leaves. An artificial atmosphere, so to speak, is formed around the cutting when it is covered with a bell-glass. "Ignorant people," Dr. Lindley remarks, "believe that the use of the bell-glass is to keep out air, which is impracticable and useless. Bell-glasses act by keeping in moisture. From the surface of warm damp soil, water is perpetually escaping in the form of invisible vapour; if the soil is freely exposed that vapour is dispersed as fast as it is formed; but when it is confined beneath a bell-glass the air is unchanged, and the vapour remains in a state of suspension, bathing and invigorating the whole surface of the cuttings. When this is well managed, the whole of the injurious effects of sunlight are prevented, and all the advantages of it secured." Great care, however, must be taken to keep the temperature of the air which surrounds the bell-glass as warm as that which is enclosed, to prevent condensation within, which would induce rottenness, or what is practically termed damping off. Cutting off the leaves of cuttings, or even reducing them in size—a very common error—should be avoided. Many cuttings will strike root if their end be placed in water, and those plants do so most successfully which are termed hard-wooded, because the dense texture of the wood prevents their absorbing too much of the water, as is the case with soft-wooded plants.

This absorption in such cuttings is one if not the principal cause of their so often damping off. Mr. Low, with a view to prevent this, has proposed to dip their ends in Collodion, an adhesive substance, impenetrable by water. Its general application is not, however, recognized. There is a singular phenomenon, somewhat analogous to irritability in animals, known to exist in vegetables, the cause of which has not been discovered by physiologists. They have, however, applied the term Vegetable Excitability to it. Its effect is the well-known fact that the young cuttings taken from trees growing in the open air will not produce roots, whereas, if the same trees were taken up and placed in a forcing-house, cuttings from them would certainly succeed.

Cuttings taken from plants growing in a cool greenhouse will, in a like manner, not succeed if placed in a propagating pit at a high temperature, but if the same plants are set in a warm house for a few days, the cuttings from them are sure to succeed.[1]

Propagation by Layering is practised in the case of roses and other shrubs which do not so readily strike by cuttings. It is somewhat analogous to Inarching, that is, forming an individual plant from the branch of another still adhering to it.

Propagation by Suckers is seldom adopted, except in the case of some hardy shrubs, and the Pine Apple. Plants originated by this process amongst the former are in general considered inferior. In the latter case it is otherwise. In good culture a sufficient stock is easily kept up for private supply by choosing the strongest suckers that are produced on the stem, which are more or less numerous according to the amount of check the plant may sustain by the formation of the fruit. Rare sorts may be wonderfully increased by retaining the stump, instead of throwing it away as is usually done after the fruit is ripened, and placing it in a damp pit, with a bottom temperature of 90°. Every latent eye would then spring, and a large amount of young plants be produced.

Propagation by Single Leaves.—The leaves of some plants produce adventitious buds upon their edges and upper surfaces, and some leaves like those of the Echeverias strike root soon after they fall on the soil. Some genera like Gloxinia, Clianthus, Gesnera, &c., require to have only the footstalk of their leaves planted in sandy soil in a proper temperature, to produce young plants. These leaf cuttings first form a callosity at their base, then roots, and lastly, a bud, from which last the future plant is organised. Some plants form this bud more freely than others, while a few seem unwilling to form it at all.

Propagation by Cuttings of the Root.—Some plants produce on their roots what are called adventitious buds, which are used for the purpose of propagation. It is a singular and beautiful arrangement in the vegetable economy that such plants as do not propagate freely by cuttings in the ordinary way, do so freely by substituting portions of the root for that of the branch. The Japan Quince, the *Cydonia japonica*, so common in our gardens, is a good example of this. It can scarcely be propagated in the usual manner, but the roots from $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter, if cut into pieces about 2 inches in length, and planted even in the open border, will take root freely, The *Acacia pubescens*, which is rarely if ever struck by cuttings of the wood, propagates freely by this method. But the most extraordinary instance within our knowledge is that of coniferous trees being so multiplied. This discovery is due to M. Neuman of the Jardin des Plantes of Paris, who, in his interesting work on propagation, states this fact in regard to the *Araucaria Cunninghamii*, and he believes that all conifers may be propagated in the same manner. His process is briefly this:—In spring the cuttings are made, being portions of the roots $\frac{3}{4}$ of an inch in diameter, and from 2 to 3 inches in length; they are planted in pots in March, and placed in a moderate temperature; in April they are transferred to a warm tan bed, and in a month afterwards vegetation becomes excited.

Propagation by Single Eyes.—This is now almost universally practised in the case of the vine, the plants so produced being remarkable for the shortness of their joints, that is the multiplicity of their buds. It is believed, theoretically, that all plants may be so increased. In some cases the eyes disengage themselves spontaneously from the mother plant, fall down, and strike root; in others the propagator cuts out the eye, with a small portion of the wood. In some plants the eyes are more excitable than in others, and hence this mode of propagation is not of universal application in practice. The rationale of this is given by Mr. Knight, in the 2d vol. of the Hort. Trans. p. 115.

Analogous with this mode of propagation is that of originating plants from knots or excrescences, which are cut out of the bark, and called by the Italians *novoli*, in English, knaurs. These embryo buds or concretions are spoken of by Dr. Lindley, as being found "in the bark of many, and probably of all trees, and are supposed to have been adventitious buds developed in the bark, and, by the pressure of the surrounding parts, forced into those spheroidal woody masses, in the shape of which we find them." These are found sometimes singly, as in the Beech, but often in groups or clusters, as in the Elm. They often remain dormant for years, at other times lengthen out into small branches. They have been seldom used for the purpose of propagation in this country, but have been so in Italy in the propagation of the Olive. The process is explained by Signor Manetti in the 7th vol. of the Gardener's Magazine.

Propagation by Budding and Grafting.—This operation is in some respects analogous to that of propagation by single eyes, buds, or cuttings. In the cases we have already treated of, the eye, bud, or scion, is transferred from the tree to the earth at once, whereas, in the present case, the bud or scion of one tree is transferred to another tree, or in other words planted into it. Grafting is so nearly akin to budding, that the French, who are great operators, do not distinguish them by separate words, but use the general term *greffe* for both. The theory has been very fully explained by De Candolle, in his "Physiologie Vegetable;" by D'Albret, Knight, and others. Mons. Thouin, in his "Monographie des Greffes," and also in "Nouveau Cours complet d'Agriculture," has described above 40 methods, while M. Louis Noisette published a description, with figures of 137 forms. The most valuable information on the subject, however, is to be found in Dr. Lindley's "Theory of Horticulture," *new edition*, 1855. Glancing only at the more important parts of our subject, we find that strong and healthy stocks increase the vigour of scions of weakly plants; hence delicate sorts of vines should be wrought upon plants of robust varieties. Delicate and shy-flowering roses, when wrought on strong growing sorts, produce and develope their flowers, which they would not do in our climate if upon their own roots; and, singular to say, the most delicate variegations are retained when budded, which would not happen if not so treated. Blossom buds of one tree may be transferred to the barren branches of another, and fruit thus produced. Buds of a variegated-leaved plant inserted into a branch of a plant of the same genus, having only green leaves, will, even should the inserted bud not push into growth, produce variegation in the leaves of the green-leaved plant. In this way, the curious *Cytisus Adami*, produced apparently by grafting *Cytisus purpureus* in *Cytisus Laburnum*, exhibits both purple and yellow flowers. The stock has also a considerable influence over the scion, and therefore great care should be taken in its selection.

---

[1] That portion of the wood, whether old or young, intended for a cutting, must be furnished with buds upon its surface. Hence those parts denominated internodes, that is, the smooth parts between two joints, as exemplified in the *Nat. Order Gramineæ*, need not be tried, but the same plants, cut transversely, close under a node or joint, root freely. In other plants, as in the Pelargonium, for example, internodes also intervene between leaf and leaf, hence cuttings of them must be made just under a leaf, because a bud is certain to exist in the axil of the leaf. Flower stalks seldom contain buds, and hence they are useless for the purpose of making cuttings.

Introduction.

Introduction.

If mere multiplication of individuals were all that was to be expected of budding or grafting, then the stocks most easily procured, if sufficiently akin to the scion or bud, would be the best. But the operation is of far greater importance than this; it ennobles the tree by changing its character from a worse to an improved condition, as to its production either of flowers or fruits. To a certain extent it increases the hardiness of a tender sort, when wrought on a stock capable of better resisting cold, or one which is more suited to the low soil temperature of northern latitudes than that natural to the tree from which the bud or scion is taken. Mr Knight denied this fact, but Dr. Lindley supports it, and says, in his "Theory of Horticulture"—"Probably in Persia, the native country of the Peach, that species, or its wild type, the Almond, is the best stock for the former fruit; because the temperature of the earth is that in which it was created to grow. But in a climate like that of England, the summer temperature of whose soil is so much lower than that of Persia, the Plum, on which the Peach takes freely, is a hardy native, and suited to such soil, and its roots are aroused from their winter sleep by an amount of warmth insufficient for the Peach. Experience, in this case, completely confirms what theory teaches; for although there may be a few healthy trees in this country growing upon the Almond stock, it is certain that the greater part of those which have been planted have failed; while in the warm soil of France and Italy it is the stock upon which the old trees have in almost all cases been budded."

Stocks must also be chosen to suit the soil. From a careful series of experiments made in the Horticultural Society's Garden at Chiswick, we find that in loamy soils the Apple succeeds best on the Doucin stock, in chalky soils on the Crab, and in light soils, slightly enriched with decayed vegetable matter, on the Doucin. The Pear in loamy soil, or in light soils enriched with decayed vegetable matter, succeeds best on the Quince, while on chalky soils the wild Pear is preferable. The Plum succeeds best in loamy soils, when wrought on the Plum stock, while on chalky and light soils it does better on the Almond. The Cherry succeeds best in loamy, or in light rich soils, when wrought on the wild Cherry, and on chalk when on the Mahaleb stock.

The stock also has considerable influence on the fruit, as well as on the strength of the scion. This we find to be the case in regard to the Stanwick Nectarine, so apt to crack and not to ripen when wrought in the ordinary way. It is said to be cured by being first budded on a very strong growing Magnum Bonum Plum, wrought on a Brussels stock, and inserting the buds close to the ground, then the buds of the Nectarine on the Magnum Bonum Plum, about a foot from the ground. The quality of the fruit is in general also improved by the process. "This may be conceived," says Dr. Lindley, "to happen in two ways—either by the ascending sap carrying up with it into the scion a part of the secretions of the stock, or by the difference induced in the general health of a scion by the manner in which the flow of ascending and descending sap is promoted or retarded by the stock. In the Pear the fruit becomes higher coloured and smaller on the Quince stock than on the wild Pear; still more so on the Medlar. On the Mountain Ash the Pear becomes earlier; and in these instances the ascent and descent of sap is obstructed by the Quince more than by the wild Pear, and by the Medlar more than by the Quince. Similar effects are produced in the Apple by the Paradise and Siberian bitter and sweet stocks."

From these facts we learn that the quality of fruit must become deteriorated when wrought on stocks, the fruit of which is worthless. For example, Peaches would be so when wrought upon the Almond or Wild Plum; the Apple, when wrought on the Crab; and the Pear, when wrought on the White Thorn or Mountain Ash. Analogy would lead us to expect that using as stocks those trees whose fruits are of known excellence, still greater excellence would follow. This is asserted to be the case. In the same way double working or ennobling is said to improve the quality of fruits, an idea we have long entertained.

Planting.—Transplanting naturally follows propagation. We will now briefly glance at the leading features of this important part of our subject. Every plant when removed from one place to another sustains, to a greater or less degree, a check. It is for us to consider how this check can be obviated, or reduced. The season of the year, the state of the atmosphere, the condition of the plant, the soil, its age, size, and the disposition of its roots, are all matters to be duly considered.

As to season, as regards deciduous trees and shrubs, it is now admitted by those most competent to judge, that the earlier in autumn the operation is performed the better; although some extend it from the period when the leaves fall to the earliest part of spring, before the sap begins to move, and the cold dry winds to prevail. Were it possible, we would say, let the operation be completed by the end of November, because up to that period the soil has not parted with the solar heat absorbed during summer; heat being, as already shewn, so necessary for stimulating growth in the roots. We are aware that in large operations this cannot in all cases be effected, but in regard to rare and delicate plants it should not be lost sight of. Early autumn planting enables the wounded parts of the roots to be healed over, and to form spongioles, which will be ready in spring to collect food for the plant, at the time it most requires it. Late winter and spring planting should, as far as possible, be avoided, for at that time the buds begin to become excited, and the draught upon the roots becomes great. Some believe that as the surface of the young leaves is small, the transpiration is feeble; but they should take into consideration that the newly formed tissue is unable to resist the drying action of the atmosphere, which is exceedingly great in spring, unless it is abundantly supplied with sap from the roots.

Not only is evaporation great in our climate at the period the buds begin to burst, but our temperature is also low, which prevents the free circulation of the sap. Indeed, as regards deciduous trees and shrubs, we are confident that the proper season for transplanting is during September, October, and November. Experience has taught us during forty years' practice, and in this we are fully borne out by our greatest physiological authority, who says, in his *Theory of Horticulture*, "As soon as a plant has shed its leaves it is as much at rest for the season as it will be at any subsequent period, unless it is frozen; its torpor is indeed greater at that time, because its excitability is completely exhausted by the season of growth, and it has had no time to recover it. If at that time a root is wounded, a process of granulation or cicatrization will commence, just as it does in cuttings; and from that granulation, which is a mere development of the cellular system, roots will eventually proceed. Now, as it is obvious, that since roots must be wounded in the process of removal, the sooner the wound is made the better, because it has the longer time in which to heal; and therefore, the earlier in the autumn transplanting is effected, the less injury will be sustained by the plant submitted to the process. Deciduous trees usually begin to assume their autumnal hue in September, and as soon as that has happened they may be transplanted with safety." The humidity of the atmosphere also, as is well known, is much greater in our climate during the autumn and winter months than in spring, and hence this season is more favourable for the perspiration of plants which, although they are enfeebled by the loss of their leaves, is not entirely suspended. Besides, the functions of absorption and perspiration are going on through their bark, and therefore a saturated atmosphere is extremely favourable to this important action.

We only refer to one other circumstance in favour of autumnal planting, and that is the production of roots during the absence of leaves. Some physiologists support a theory, that roots are formed by the action of the leaves, and therefore that trees make no roots during winter. This theory is, however, unsupported by facts, for it is proved that roots do grow during that period.

Closely connected with the proper season is the best means of performing the operation of transplantation. This depends greatly on the size of the trees, the soil in which they grow, and the mechanical appliances made use of in lifting and transporting them. The smaller the tree, the more successfully can it be removed. The more argillaceous and the less silicious the soil, the more readily can balls of earth be retained about the roots. Most planters prefer balls, some, however, care less for this, so long as the roots are preserved to their greatest possible extent. Others lay great stress on the preservation of the spongioles, while all admit them to be indispensable as absorbing points, destined to collect food for the plant, which derives nourishment from them by means of the roots. The point principally disputed is the necessity of preserving them during the process, or the practicability of allowing them to be cut off and replaced again. Their careful preservation has been strongly advocated by De Candolle, Dutrochet, Bonnet, Papin, Sennebier, Keith, and Lindley; while Link, Ohlert, Rogers, and others, deny this to be a matter of consequence. Trees and shrubs removed from thick plantations, or from sheltered warm places, are ill fitted to be planted in bleak and cold places. During their removal it is important that the roots be in some way covered, if only to prevent their suffering from being dried up by the action of the air, so that they may retain nearly the same degree of humidity which they had when growing in the soil. Damp days are therefore the best for the operation, hence March, April, and May being our dryest months, are the most unfavourable. Of mechanical appliances, there is no doubt that M'Glashen's tree-lifter, where the soil is free of stones and of sufficient depth, is the best at present in use, and that the common timber carriage or janker is comparatively a barbarous invention.

The best time for removing evergreens is during August and September, or during April and May. The month of September, however, should have the preference. But they may even be safely planted, if judiciously gone about, at any time from April till the end of October. Evergreens differ from deciduous trees, inasmuch as they have no season of repose, that is to say, they are in a perpetual state of growth, their circulation, assimilation, transpiration, and process of root-making, being continually in operation. Much of the success in transplanting depends on the humidity of the atmosphere at the time the operation takes place; but the principal point of importance is warmth in the soil. Humidity can be supplied artificially, but heat cannot. It is upon this temperature of the soil that Mr Glendinning appears to found his arguments in favour of September planting, as described by him in an excellent paper in the "Journal of the Horticultural Society," and his opinion is one in which theory and practice completely coincide.

Pruning.—Lindley says "that if well directed, pruning is one of the most useful, and if ill directed, it is amongst the most mischievous operations that can take place upon a plant." The object of pruning is to regulate the number and bulk of the various parts of a plant, to modify the form of trees, to promote the growth of timber in forest trees, and the formation of blossom buds in fruit trees, to cure disease, proportion the head to the roots, or increase the size of the fruit. In fruit-bearing trees, it is performed on the roots to induce fruitfulness.

The season for pruning varies according to the nature of the tree, but in general it is performed at mid-winter or mid-summer, practically called winter and summer pruning. The latter should, properly, extend during the greater part of the growing season of the tree, beginning with disbudding or finger pruning, and ending by a reduction of points of the shoots where not specially required, to admit light and air to the ripening crop and young wood. Early autumn pruning has the effect of strengthening the shoots of the succeeding season, and by some is said to hasten the ripening of the crop, a fact we are unable to certify. The former is thus accounted for by Dr. Lindley, "During the season of rest (winter) a plant continues to absorb food solely from the earth by its roots; and if its branches are unpruned, the sap there and then introduced into the system will be distributed equally all through it. If late pruning is had recourse to, and the branches are removed, of course a large portion of the sap that has been accumulating during the winter will be thrown away. When, however, early or autumnal pruning is employed, and the branches removed before the sap has accumulated in them, then all the sap which the roots are capable of collecting during the period of repose will be deposited in the branches left, and they will necessarily push with increased vigour. As, however, pruning is by no means intended at all times to increase the vigour of a plant, late or spring pruning, if not deferred till the sap is in rapid motion, may be more judicious." Hardy trees and shrubs, with few exceptions, may be pruned during autumn and winter, the most tender should be left till spring, lest they suffer from frost while their wounds are unhealed. Besides many of them lose portions of their branches, and the extent of this loss cannot be determined till spring.

Pruning is an art which requires experience, and a knowledge of the character of the plant to be operated upon. Two important lessons require to be learned, namely, how to cut, and where to cut. The cut should be clean, and always in a sloping direction upwards, at about an angle of 45°, and this can only be performed with a very sharp and thin knife. The cut should commence at the back of the bud, and not on the opposite side of the shoot, as by this means the bark soon covers over the wound. When the cut is too low, leaving the bud exposed, it is faulty, because the bud is exposed to the drying air, and is liable to be broken off. Cutting too far above a bud is equally bad, as it leaves a dead portion of the branch which can never be covered with bark, and must either be cut away afterwards, or left, as it often is, a staring evidence of want of care or skill in the operator.

The question of pruning, or cutting back trees at planting, is a disputed point amongst horticulturists. The matter has been explained in "The Theory of Horticulture," of which the following is the substance:—In pruning plants, when transplanted, there can be no doubt that it is more frequently injurious than beneficial. The roots of a transplanted tree not being fully in action in consequence of the injuries sustained during its removal, they are capable of exercising but little influence on the branches, as compared with an established tree, and therefore heading back the branches will not cause the buds to break with more force than if the pruning had not been performed. The great point to be attained, in the first instance, is the renovation of the roots, and that will happen only in proportion to the healthy action of the leaves and buds; if, therefore, the branches are removed, a great obstacle is opposed to this renovation; but if they remain, new roots will be formed in proportion to the healthy action of the leaves. The danger to be feared is that the transpiration of the leaves may be so great as to exhaust the system of its fluid contents faster than the roots can restore them; and in such cases it is certainly requisite that some part of the branches should be pruned away. The shortening of the roots at the time of planting, although pretty universally practised in nurseries, can only be useful in cases where they have sustained injury in course of their removal. In all cases, therefore, where roots have been broken or bruised, it is proper to cut off the injured parts smoothly, in order to prevent decay and to promote the formation of granular matter along the edges of the wounds, from which new fibres or spongioles are certain to be produced. This operation, however, should take place in autumn, when the roots are comparatively devoid of fluid, and not in spring, when they are fully charged.

Summer pruning consists merely of a removal of all young wood not required for the extension of the tree or formation of fruit-buds. One species of summer pruning should be here adverted to, namely, a partial removal of the leaves. This is a dangerous operation in unskilful hands, as by means of the leaves the important functions of digestion and respiration are carried on. Strip a tree of its leaves during its growing season, and it dies; reduce their number, and a reduction of its energies is the consequence. Hence it is only with the greatest care that a few leaves may be removed towards the ripening season to admit light and air to assist in the ripening of the fruit and the maturation of the young wood.

Training.—The sap in all trees has a natural tendency to flow upwards, and hence the buds at the extreme points of the branches will be the strongest and most disposed to produce leaves and wood. Upright training is consequently the best when these results are desired, but the worst when fruit is desired; and hence a contrary direction, or some modification from the perpendicular, should be given to the branches. Again, weak growing trees should have their branches trained perpendicularly, or nearly so, while strong growing ones should be placed in a horizontal or even pendant position. We find trees trained between these extremes, and all that practice has exemplified in the various modifications is borne out by the soundest theory. It would be quite out of place here even to give an enumeration of the various forms. We will, however, give a few illustrations of the most popular forms in their respective places.

FRUIT AND KITCHEN GARDEN.

Although fruits and culinary vegetables are for the most part cultivated within the same enclosure, and even in many works on the subject of their management we find them treated as inseparable, yet it will be found best in practice, particularly where high culture is attempted, to keep the culinary garden and that dedicated to fruit-trees distinct. This systematic arrangement, however, applies more especially to large establishments, where order and system are considered leading features. Grave objections may be also raised against placing hot-houses, plant-houses, and often a large amount of flowers, in juxtaposition with cabbages and potatoes, and even with one another. In places of limited extent, this medley system can scarcely be avoided. The *beau ideal*, however, of a perfect garden establishment would be to have each department a perfect whole in itself; and these may be so arranged as to adjoin each other, or be separated, according to local circumstances. Long cherished associations (prejudices, may we call them?) will require much softening down, ere the promiscuous style be entirely abandoned. Unfortunately we have only few examples to adduce in favour of the systematic style; yet, when it has been adopted, an ample amount of satisfaction has been the result.

The first thing to be considered is the *plan* of the garden. This should be prepared before commencing operations, and in it should be laid down the most minute arrangement even of all the details. It does not, however, follow that the proprietor is to carry into effect the entire plan at once, or possibly, in many cases, at any future period. He can adopt such parts of it as suit his taste or circumstances at once, and when afterwards disposed, proceed from time to time with the remainder. The want of such an arrangement at the outset accounts for the confusion and want of unity displayed in many gardens of high standing. Indeed we have few instances to point to, in which the grossest incongruities are not to be found.

Size.—The size of a walled garden ought evidently to bear some proportion to the splendour of the mansion-house of which it is an appendage, and to the extent of the park. In style also, in its principal erections, it should harmonise with that of the proprietor's residence; and although the architectural details are not required to be carried out in all their minutiæ, still so much of them is required as to show a connection between the one and the other. Such a garden should comprehend from four to six acres. In many places this extent will not afford an adequate supply of culinary vegetables, and therefore, as at Chatsworth, Petworth, Belvoir, Dalkeith, &c., the extent varies from twelve to twenty acres, and that of Her Majesty at Frogmore exceeds thirty acres. From an acre and a half to three acres may, however, be regarded as forming a good size for a garden, it being always better, in the first formation of a garden, to enclose too large a space than too small a one. Some, from mistaken notions of economy, attempt to procure a supply of the hardier vegetables from the farm; but, with the exception of the winter supply of potatoes, nothing can be so well or economically produced as in the garden.

Situation.—The position of the garden in relation to the mansion-house properly belongs to the province of Landscape-Gardening, as it obviously should be in keeping with the general features of the park scenery. As a place of interest to every well-informed proprietor, it should be so near as to be conveniently accessible on foot, probably within little more than a quarter of a mile; while it should be so distant as to avoid the possibility of offence arising from gardening operations and the resort of workmen. A position on either side of the house is to be preferred, unless a much better can be found behind it. Wherever it be placed, it should be so masked by evergreen shrubs and trees, as not to be visible from the principal lawns, nor from the walks in the shrubbery and flower-garden. If the surface of the domain be undulating, the garden is almost unavoidably seen from some point or other, and the *coup d'œil* of the enclosure walls, presenting the idea of a large box, is apt to produce an unpleasant impression, which should by all means be avoided or lessened by plantations judiciously placed. Where the irregular form of exterior enclosure is adopted, this great defect is obviated; and gardens in this form present many advantages over those of stiff and formal shapes; while, at the same time, space is secured in the surrounding slips for furnishing an abundant supply without the expense of high walls. Also much of the formality of regular figures is taken off when south walls are either dispensed with, as exemplified in the new gardens recently laid out by Mr. M'Intosh at Braco Castle and Maulsden; or where they are transformed into sunk terrace walls, as in the new gardens at Panmure House and elsewhere.

Ground possessing a gentle inclination toward the south is desirable for a garden. On such a slope effectual draining is easily accomplished, and the greatest possible benefit is derived from the sun's rays. The lower part of a gentle declivity is perhaps to be preferred; but a very low situation should never be chosen, as the subsoil is apt to be damp, fogs often brood over such spots, and frosts are more injurious there than on higher ground. It is beneficial to have an open exposure towards the south, the east, and west, so that the garden may enjoy the full benefit of the morning and evening sun.

Shelter is absolutely necessary; and that afforded by natural objects, such as rising grounds, is the best. Where this is wanting, its place should be supplied by masses of forest-trees, disposed at such a distance, however, as not to shade the wall-trees, perhaps not nearer than 150 feet. The purpose of such screens is to break the force of the winds; and as every situation is, in this respect, liable to some peculiarities occasioned by the general structure of the country, as for instance to aërial currents from adjacent eminences, these peculiarities should be carefully observed and obviated. The idea that crowded plantations increase the warmth of a place is fallacious; and, in the opinion of many, they do more harm than good, by producing an unhealthy atmosphere.

The trees employed may be various, but lime-tree, horse-chestnut, beech, sycamore, weeping birch, and the smooth-leaved wych elm, should prevail. There may also be a proportion of evergreen trees, such as hollies, Portugal and common laurels, and evergreen oaks. When these masses of wood are planted at the time the garden is formed, poplars, and other fast-growing trees, should be thickly intermixed to act as temporary trees and nurses, which are afterwards to be weeded out, as the permanent trees more slowly advance to maturity.

"Experience," says Towers, who has written most judiciously on this subject, "has proved the correctness of Forsyth's opinion on the prevalence of blights in situations surrounded by woods." "I believe," he says, "that prevalence to be dependent on the phenomena of conduction, effected by the proximity of innumerable vegetable points, by which the chemical constitution of the atmosphere is somewhat changed, so that the juices of the plants partake of the change, and acquire a saccharine quality. Insects are thereby enticed, but not produced; and in every case of blight, it appears much more probable that the altered or diseased juices invite the insect than that it is imported by this or that current of air, whether it blow from the east, or from any other point."

The points from which shelter from winds is most required, varies very much according to the geographical position of the place. Thus we find by the calculations of the Royal Society of London that the prevailing winds in England are as follows:—S. W. 112 days, N. E. 58, N. W. 50, N. 16, S. 18, W. 53, E. 26, S. E. 32. And according to Dr. Meek, from observations taken during 7 years, the prevailing winds of Scotland are—S. W. 174 days, N. E. 104, S. E. 47, and N. W. 40 days. And it may be stated that the prevailing winds in Scotland are the same throughout Europe, namely S. W. and N. E.

Those prevailing in Ireland, from its geographical position, are W. and S. W.

Water is one of the most important elements in vegetable life. It is, as Switzer remarks, "the life and soul of a garden."

Yet we do not find one garden in twenty, where even ordinary precautions have been taken to secure a competent supply. Rain water is the best, next to that, river or pond water, and last of all, that from springs. A chemical analysis, however, should be made of its properties, before the expense of bringing it in is thought of. Many waters containing mineral ingredients are exceedingly injurious to vegetation. Iron pipes are the best conductors, and they should lead to a capacious open reservoir placed *without* the garden, and at the highest convenient point of level, to secure sufficient pressure, so that not only the whole surface of the ground, but the wall trees also may be conveniently watered. Short flexible tubes should be made to fit on branches of the main pipes, so as to traverse the whole garden, and these of a calibre capable of conducting a supply even to the extent of irrigation in certain cases. They should also be placed under the walks for safety, as well as for being easily reached when repairs are required. Pipes should also be laid having a connection with an underground cistern and a communication with every hot-house, as well as with the various offices.

Notwithstanding the vast importance of water, it is far from expedient to admit of large basins or ponds, and far less of a running stream through a garden, unless they can be completely turned off during winter. Where water is introduced, whether by bringing it from a distance in pipes, or by raising it to the surface by means of artesian wells, the expenditure, be it what it may, will, in the long run, be far less than what attends the very imperfect means employed in most gardens.

There are many contrivances by which water can be procured in abundance in almost all situations. We may merely refer to Lucas's self-acting force and lift-pump, the hydraulic ram, and other mechanical appliances.

Connected with the situation is the *approach* to the garden from without, a matter requiring some taste and contrivance. If possible, it should be from the south, when the range of glazed houses will be seen at once, and produce a pleasing effect. Sometimes a lateral entrance is very suitable, leading, it may be supposed, from the flower-garden through an intermediate shrubbery, and coming upon the hot-houses in flank. Such would be the case in passing from one garden to another, as we have previously suggested, and much more so, if the department in which the principal hot-houses are placed, be entered, so as to get the first *coup d'œil* of them from a point nearly in a parallel line with their front. The worst of all entrances is from the back or north.

Form.—The form of a garden, it is obvious, must chiefly be determined by the nature of the situation and the taste of the proprietor. In general, gardens are either squares or oblongs, chiefly, it is presumed, because walls of this configuration contain the greatest space within the least perimeter, a result of very questionable value. They may be of any form, with this limitation, that attention should be paid to facilitating the transport of manures and garden products, for when the grounds are straggling, or complicated in structure, the labour of cultivation is much increased. Straight lines of walls and geometrical forms are perfectly admissible when near a mansion of a high architectural character, but not when the mansion which may be considered as the datum point is so subordinate as to fall under the denomination of a cottage or picturesque structure. In this case a garden of an irregular form will be in much better keeping. Prejudice is strong against gardens of irregular form, but when well adapted to the conditions of the locality they are far from being objectionable, as they associate better with surrounding objects and forms.

Exterior Fence.—All gardens should be encircled by an outer boundary, formed by a sunk wall or ha-ha, surrounded by an invisible wire fence to exclude hares, or by a hedge and low wire fence on its inner side. Occasionally this sunk wall is placed on the exterior of

Fruit and Kitchen Garden.

the screen plantations, and walks leading out among the trees, to give favourable views of the adjacent country. Although the interior garden receives its form from the walls, the ring fence and plantations may be adapted to the shape and surface of the ground. The spaces between the outer fence and the walls are called *Slips*, and, where circumstances render it eligible, a considerable extent of ground is sometimes included, and appropriated to the culture of small fruits and vegetables. If possible, the gardener's house should be situate here, as being convenient for him, and as tending to scare depredators.

Walls.—For the production of the finer fruits, such as peaches, apricots, hardy grapes, and most of the delicate French and Flemish pears, the aid of walls is indispensable in our climate. Indeed in the northern and higher parts of the country, where there is no walled garden, the dessert can seldom consist of more than small fruits, and ill-ripened apples and pears. The north wall having, in the interior, a south aspect, is of course appropriated to the more tender kinds of fruit-trees; here, it is generally estimated, they enjoy an increased temperature equal to 7° of south latitude; that is to say, the mean temperature within a few inches of their surface is equal to the mean temperature of the open plain 7° farther south. The east and west walls are set apart for fruits of a somewhat hardier character.

The north wall is generally placed nearly perpendicular to the meridian, that is, so as to have the sun directly in front at 12 o'clock. Minute directions have indeed been given to make it face towards 11 or 11½ A.M., on the ground that thus it would sooner meet the rays of the morning sun; but it does not appear that this arrangement has been the subject of direct experiment, and certainly the arguments, by which the superiority of this aspect is supported, are far from being satisfactory. The east and west walls are commonly placed at right angles to that already mentioned, but they may follow the shape of the ground, and if this slope to the south, they descend with the declivity. This descent, however, should not be carried in a direct line parallel with the surface of the ground, but should be stepped or ramped, so that the cope may be level between each of the breaks. South walls are the most valuable in cold climates, and against them the hot-houses have generally been placed. This appropriation of them along the northern side of the garden, has led to the erection of a corresponding wall on the southern side also, and not unfrequently, when the garden is large, a cross wall is carried through the centre. To such walls there are objections, inasmuch as they shade the ground behind them, and render it cold by the exclusion of solar heat. The only advantage gained by them is that of their southern side, the opposite being next to useless, as no fruit-trees trained against it derive any advantage above being planted as open standards. Such walls also give the garden a confined appearance, and practically render it cold and deficient in ventilation. It is better, therefore, to extend the length of the principal wall beyond the space covered with glass, or to place the hot-houses in the centre of the garden, or, still better, in a compartment by themselves, constructing them of glass on all sides to within two feet of the ground, in the span-roofed, ridge and furrow, or curvilinear fashions. Thus little or no shade would be occasioned by them, and the front or south side of the garden would be open to the sun and air. The fence surrounding the slips will afford sufficient protection, or if no such exterior fence exist, the ends of the east and west walls may be connected by a rabbit-proof wire fence. However, as walls with a southern exposure are of so much importance for the ripening of our superior fruits, these ends may be better secured by running sunk or terrace walls across the ground than by the lofty walls at present in use. Where the inclination of the ground is considerable, such walls may not only be readily constructed, but they give a character of design as well as of utility at the same time. Their top should in no case rise more than three feet above the level of the ground behind, and a gravel walk should run parallel to them. As dryness is favourable to an increase of heat, it is necessary that such walls be either built hollow, or that they be packed behind to the thickness of three or four feet with rubble stones, flints, brickbats, or similar material, thoroughly drained at bottom, and forming the foundation of the walk referred to. Where the inclination of the ground is not great, then sunk walls may be employed, and the ground in front of them sloped back, so that the rays of light and heat may not be intercepted. Walls so situated will be warmer and much more sheltered than such as are built entirely above the surface.

Fruit and Kitchen Garden.

Regarding the height of walls, it is better to extend the surface by elongation than by carrying them to a great height. Twelve feet is in general taken as the average height, but this depends greatly on the extent enclosed. The largest garden should have its northern or principal wall 14 feet, and its side walls 12 feet in height. Spaces of an acre or so should have their principal walls 12 feet and side walls 10 feet in height. It is important to extend projecting wings to the extent of 12 feet, or the breadth of the exterior border at the four corners of the garden, as they break the force of the wind considerably. It is better, however, that these projections extend in a diagonal direction rather than in a straight line with the wall.

Material.—Bricks have almost universally been employed in England for this purpose, because brick is the material of the country. For a similar reason stone has, until within late years, been greatly used in Scotland. The manufacture of bricks has now reached as great perfection in the latter country as in the former, and the means of procuring them in all parts has led to their more general adoption. The principal advantage of brick walls is that they can be more readily built hollow than stone walls, which is of itself important. The cavity (about 9 inches) between the sides of the wall renders them dryer than any solid wall, as the capillary attraction of damp is arrested; and the more so as the cavity is charged with air admitted through small openings placed near the surface of the ground. Such walls also readily admit of having hot water pipes placed in them. A considerable economy in material is effected, and an equally strong wall is the result. Bricks cannot be too well burnt for garden walls; the harder they are the less moisture will they absorb. Their colour becomes softened down during the process from the harshness of brick colour to that of a dark stone colour, which is more in harmony with all surrounding objects. A prejudice, indeed, was long felt in favour of bricks, on account of the facility they afforded for training trees. That prejudice, however, is now set aside by the use of eyed cast-iron studs (*vide* fig. 1), which are placed in the wall during its erection, and pushed into the joints before the mortar becomes set. They are placed in straight lines, both vertically and horizontally, and are permanent. For Peaches, &c., they are 9 inches apart, and for Pears, &c., 15 inches. The trees are fastened to them by passing a piece of soft twine through the eye and round the branch.

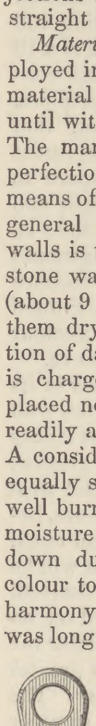

Fig. 1.

Many excellent walls are, however, built of stone.

Fruit and Kitchen Garden.

The best is dark-coloured whinstone (*the greenstone and basalt of mineralogists*), because it absorbs a very small amount of humidity. The best, however, in Scotland would be Caithness pavement, 4 inches thick, which absorbs even less moisture than the celebrated Bangor slate. Walls of that material could be built in regular courses, and cut (in the quarries) to any required length.

Common rubble walls are the worst of all, and where necessity compels their erection, they should be covered with Portland cement, and drawn off in imitation of ashlar.

Coping is an important element in garden walls, both for their preservation, and for throwing the rain-water off their surfaces; for, whatever produces dryness, tends to increase heat. The extent to which the coping should project must be regulated by local circumstances. On the west coast of Britain, where a much greater amount of rain falls than in the midland, and more especially on the east coast, the projection should, for a 12 feet wall, be 5 inches. In the very dryest districts 1½ inch, or merely as much as will throw the drip clear of the wall, but not of the trees, will be sufficient. A broader projection would deprive the trees of their natural supply of moisture by rain or dews. Of all material none is better than Caithness pavement.

As regards colour, no doubt black absorbs more and reflects less heat than any other colour; yet, although this is scientifically true, in practice little benefit is found to be derived from it.

Hot Walls.—Heating walls by means of smoke flues, as formerly practised, is worse than useless; and we may add, the application of the flues was just the reverse of what it ought to have been. The effect of a furnace on a smoke-flued wall is only to the extent of heating 400 superficial feet, or, in other words, 40 feet in length of a 10 feet wall; whereas the same furnace and the same consumption of fuel applied to a boiler and hot water pipes, will heat more efficiently 3000 superficial feet, that is, 300 feet in length of a 10 feet wall. In arrangement the boiler should be placed in the centre of the space to be heated, and the circulation made to flow right and left, on either side. The disadvantage of smoke flues is, that with them it is impossible to guard against extremes of heat at certain parts; that part nearest the furnace being too hot for the trees, while even towards its limited extremity little heat is perceptible. Also they discolour the wall by soot-stains which it is difficult to remove.

The advantage of heating by hot water consists in its greater economy and uniformity of operation, the wall deriving as much heat at 150 feet from the boiler as it does close to it. The first expense is doubtless somewhat greater, but it requires no expense afterwards. East and west walls are better adapted for heating than south ones, because in them the trees on both surfaces derive an equal heat, whereas, in the other case, much of the heat will be absorbed by the side from which no good is to be derived. The application of artificial heat to walls should on no account be practised in early spring, because the later the trees become excited and the blossom formed, the greater chance have they of escaping our spring frosts. The whole use of heated walls is to increase our summer temperature, and prolong it as late in autumn as will secure not only the ripening of our finest fruits, but also the ripening of the wood and maturation of the buds for the following season.

Espalier-Rails.—Subsidiary to walls as a means of training fruit-trees, espalier-rails were formerly much employed, and they still prevail in many parts of the country. In their simplest form, they are merely a row of slender stakes of larch, driven into the ground, and connected by a slight rod or fillet at top. Espalier-rails of wood, formed into pannels, fixed between upright standards, set on (not in) stones, are also employed. Their expense has, however, in most cases, been found nearly as great as that of walls of the same dimensions, while the advantage to the trees has been comparatively little. Cast and malleable iron rails have also to some extent been erected, but the well known property in all metallic substances to act as powerful conductors of both heat and cold in equal extremes, has led to their almost entire disuse. Modern improvements in pomology have shown that dwarf standard trees produce as fine fruit, and at a vastly less expense than espaliers, whether set in a vertical or horizontal position.

Fruit and Kitchen Garden.

Soils.—It is of great importance that the ground selected for a garden should be naturally of a good quality. A hazel-coloured loam, of a light or sandy texture, is well adapted for most crops, whether of fruits or culinary vegetables. As it is more easy to render a light soil sufficiently retentive, than to make a tenacious clay sufficiently porous, a light soil is preferable to one which is excessively stiff and heavy. It is advantageous to possess a variety of soils; and if the garden be on a slope, it will often be practicable to render the upper part light and dry, while the lower remains of a heavier and damper nature. The soil should be good to the depth of three feet, and any necessary additional deepening by manures or otherwise, should not be neglected. The nature of the subsoil demands particular attention. If it be strongly impregnated with metallic substances, or composed of cold till, it will prove pernicious to the roots of fruit-trees, and will scarcely admit of a remedy. A decomposing rock, or a bed of sand, is preferable. Perhaps the best of all is a dry bed of clay, overlying sandstone, which crops out within the enclosure. If the inferior strata be retentive, and if water lodge in any part of the garden, draining should be carefully executed, so as to carry off the superfluous moisture.

Irrespective of the removal of water, drainage is of vast importance, by admitting air, and with it solar heat, to the roots of plants. Vegetable physiology teaches us that plants depend greatly on a supply of air to their roots, and if it be denied them they ultimately perish. (See *Wall Borders.*)

The thorough drainage, and even vaulting of fruit-tree borders cannot be too much insisted upon, nor should gardeners overlook the important fact that drained land is in summer from 10° to 20° warmer than water-logged land lying contiguous to it. Professor Schabler, long ago, came to the conclusion, that the loss of heat, caused by evaporation in undrained lands, amounted from 11¼° to 13½° Fahr. Mr Park has also shewn, in his "Essay on the Philosophy of Drainage," that the thermometer in drained moss land rose in June, 1837, to 66° at 7 inches below the surface, while in the neighbouring water-logged land it would never rise above 47°. In the garden of the Hort. Soc., the mean temperature of the thoroughly drained soil at 1 foot below the surface, in the month of July, is 63° 49′, so that, if we take that of water-logged land to be the same as spring water, or 47°, there is a gain of 16½°. The reason why drained land gains heat, consists in the well known fact that heat cannot be transmitted *downwards* through water. The experiments made on vaulted borders at Yester bear out these facts in a remarkable manner.

Preparatory to the distribution of the several parts of a garden, it is proper that the ground be trenched to the depth of three feet at least; but the deeper the better. In this operation all stones larger than a man's fist are taken out, and all roots of trees, and of perennial weeds, are carefully extracted and cleared away. When the soil is not tolerably good to the depth of three feet, it will often be proper to remove a portion of the subsoil; and its place should be made up by a proportional quantity of turf or fresh loam from the fields. If the subsoil be gravel, and the upper layer sandy, the additional earth should be clayey loam; but if the original body of soil be of a compact texture, the materials introduced

Fruit and Kitchen Garden.

should be mixed with sand, marl, and other light opening substances. When the whole ground has been thus treated, a moderate lining will, in general, be useful. After this, supposing the work to have occupied most of the summer, the whole may be laid up in ridges, to expose as great a surface as possible to the action of the winter's frost. The draining, trenching, and other operations here recommended, will unavoidably be attended with considerable expense, which will not immediately be followed by any perceptible beneficial result. The lapse of a few years, however, will develope the vast advantages of such a mode of procedure, which, if neglected at first, cannot be adopted at a subsequent period but with indifferent success, and a great increase of care and labour.

Manures.—In enumerating the general appendages of gardens, it may be proper to say something of manures. Where there are extensive melon grounds, an abundance of stable and other litter is required; and this substance, in its partially decomposed state, as afforded by exhausted hotbeds, supplies a manure well adapted to aid the processes of vegetation. Decayed leaves, which are plentiful where there are extensive pleasure-grounds, also form an excellent manure for many purposes. Some practical men prefer composts, or such substances as have undergone fermentation, to simple dungs. For fruit-trees, turf from rich pastures, mixed with vegetable earth, is the best stimulant which can be applied. No trees are permanently benefited by the application of crude manures to their roots; and it is certain that many have been irremediably injured by this practice. But whatever caution may be necessary in their use in the fruit-garden, the prudent horticulturist will find it expedient to pay particular attention to the collection of manures. He cannot go on long without them in the kitchen-garden; for ground which is exhausted by continual cropping, requires to be continually repaired.

Internal Arrangement of Gardens.—A considerable portion of the north wall is usually covered in front with glazed structures, called hothouses, or forcing houses. To this practice there are exceptions. (See *Forcing Garden.*) To these the houses for ornamental plants are sometimes attached; but the last are more appropriately situate in the flower garden, when that forms a separate department. It is well, however, that every thing else connected with the forcing, whether of fruits or flowers, should be concentrated in one place. The melonry and pine-pits should occupy some well-sheltered spot in the slips, or on one side of the garden. Adjoining to this may be found a suitable site for the compost ground, in which various kinds of soils may be kept in store, and composts prepared. To this department free access should be had, so that carts may be admitted, a precaution seldom thought of, until the inconvenience is discovered by the increased expense and labour of wheeling in and out material.

Extensive gardens, in exposed situations, are often divided into compartments by hedges so disposed as to break the force of winds. Where these are required to be lofty yet narrow, holly, yew, or beech is preferred; but if space be no object, common laurel-bay is one of the most beautiful plants that can be employed for this purpose. Smaller hedges may be formed of evergreen privet, or of tree-box. These subordinate divisions, though often neglected, are worthy of attention; for, in addition to shelter, they furnish shade, which, at certain seasons, is peculiarly valuable. Gardens upon a large scale, and especially those laid out in the irregular manner, may have narrow belts of shrubbery running through them, producing picturesque beauty, and affording, at the same time, shelter and shade. These should be planted on elevated borders several feet above the general surface, combining all the beauties of the shrubbery and the utility of the kitchen-garden. And this is the more necessary if these shrubberies be so broad as to admit of walks passing through them, with occasional openings or outlets to the culinary departments.

Fruit and Kitchen Garden.

The distribution of the area of the garden in walks, borders, and compartments, may be regulated very much by the shape of the ground and the taste of the owner. In general, a gravel walk, six or eight feet broad, is led quite round the garden, both within and without the walls. A walk of similar dimensions is often constructed in the centre of the garden in the direction of the glazed houses, and this is sometimes crossed by another at right angles. Some times these walks are led diagonally from the corners. The space between the wall and the walk that skirts it, is called the wall-border, and is commonly from fifteen to twenty feet broad. On the interior of the walk there is usually another border five or six feet broad, which is generally occupied by fruit-trees trained to espalier-rails, or by dwarf standard trees. The middle part of the garden is divided into rectangular compartments for raising the various culinary crops. It is advantageous to have several small beds, in which to cultivate the less bulky articles, such as basil, sage, tarragon, &c., which, in large spaces, are apt to be overlooked or neglected.

Wall-Borders.—The preparation of borders for fruit-trees is a matter of the utmost importance, and no pains should be spared upon them. Where borders are not in good condition, the care and toil of the most experienced gardener will avail but little to the production of fruit. The most perfect wall-tree borders must be admitted to be those that are vaulted below, and have the soil for the roots placed upon a pavement flooring, which is supported by stone or brick piers, so constructed as to leave a cavity below of eighteen inches or two feet, into which air is admitted by small vertical eyes, placed along the edges of the walk and covered with open iron gratings. The next are those having earthenware tubular drains laid across the border, at distances of from eight to ten feet, with openings both at the side of the walk and also along the bottom of the wall, so as to introduce a circulation of air. Over these drains rubble stones, flints, brickbats, or similar material, are loosely laid, and these are again covered by a coating of coarse gravel, upon which the soil is to be placed. It is important, even beyond these precautions, that drains be placed so as to render the bottom perfectly dry. Formerly concrete and impervious bottoms were recommended, with a view of preventing the roots penetrating into the subsoil or descending too deep, and being beyond the reach of solar heat and air. Such bottoms were found defective, inasmuch as they retained water, and consequently excluded air. Good soil to the depth of two feet and a half is quite sufficient for any fruit-tree, it being better to extend the range of the roots horizontally than vertically, hence such borders should not be less than twelve feet in breadth. It is also well to give them a fall of six or eight inches from the wall. Three-fourths rich loam, and one-fourth light sandy earth, form a mixture congenial to the generality of fruit-trees.

Fruit-tree borders should never be cropped with culinary vegetables, the process of digging destroys the roots of the trees, which should, by every possible means, be induced to keep near the surface. In selecting the soil, regard may be had to the particular trees which are to cover different portions of the wall. Thus, a heavy soil may be allotted to pears and plums; loam of a medium character, inclining to be strong, to peaches, nectarines, and apricots; and a lighter earth to cherries and figs. Above all, care should be taken to render the borders sufficiently rich and substantial at their formation.

Standard Fruit-Trees should not be planted, if it can be avoided, in the borders of the kitchen-garden. Their roots are either mangled by digging about them, or their growth becomes too luxuriant, in consequence of the soil becoming too rich. They shade and injure other crops, and destroy that unity of expression which ought to exist in every highly kept kitchen-garden. They should be planted in the outer slips, where they may be allowed to attain a large size or be kept in a dwarfish state. Each sort of fruit should be planted by itself, to give an appearance of order and system, as well as to facilitate their protection by being covered with nets.

THE FRUIT GARDEN.

We shall first direct our attention to the culture of hardy fruits, or of such as, in our climate, do not require the assistance of much artificial heat. But before proceeding to a minute detail of the management of the different varieties, it may be proper to attend to some of the operations which are common to all.

The Preliminary Operations may be classed under the heads, Propagation, Planting, Training, and Protection of Blossom.

Propagation.

Propagation of Fruit-Trees by Seed.—Although fruit-trees are furnished with all the natural means of reproduction, it is not in general expedient to attempt to propagate them by the sowing of seed. This method is found to be equally tedious and precarious, requiring the labour of many years; and after all, existing varieties of fruits can be propagated by seed, so as to resemble the parent tree upon which they grew, only to a very limited extent; and the chance of an improved variety being produced by their means is exceedingly rare. This is so far owing to the great change which took place in the individual at the period of its origin, when by some cause to us unknown it appeared possessed of properties superior in size, colour, and flavour, to its parent. In other words, a seed is capable of growing into a new individual of the *same species*, but not, in the case of our cultivated fruits, into the *identical variety* of that species. In the great majority of cases, while the new individual retains its *specific characters*, it will be very different from *the variety*, in general very inferior to it; for, following a natural law, it will recede towards its original type, *e. g.* the wild crab in the case of the apple, and the almond in the case of the peach. "But while it will with certainty become the same species as that in which it originated, it does not possess the power of reproducing any of the peculiarities which may have existed in its parent. For instance, the seed of a Green Gage Plum will grow into a new individual of the Plum species, but it will not produce the peculiar variety called the Green Gage. This latter property is confined to leaf-buds, and seems to be owing to the seed not being specially organized after the exact plan of the branch on which it grew, but merely possessing the first elements of such an organization, together with an invariable tendency towards a peculiar kind of development."—(Lindley's *Theory of Hort.*) All our present admired fruits are regarded as seminal varieties obtained from the wild inhabitants of the forests, which have been trained into an artificial condition; and when sown seem to have a tendency to resume their original constitution. In the peach-orchards of America, for instance, which are planted with the kernels of choice sorts, there are seldom more than a few trees affording fruit fit for the table; the produce of the majority being so worthless, that it is usually employed for feeding hogs. Notwithstanding this inconvenience, there are some considerations which render this mode of propagation at once interesting and important to horticulturists. It is the only way by which we can procure new kinds of superior qualities. The late Thos. And. Knight promulgated the theory that by rearing fruit-trees from seed he could produce a re-invigoration of our older varieties, which he believed to be hastening to decay, if not total extinction; and further, that new generations of fruits reared from seed would become hardier and better adapted to our climate, by what he denominated acclimation. Modern vegetable physiologists deny the truth of both these theories, and assert that no deterioration has taken place in even our oldest fruits, some of which have been in cultivation since, if not prior to, the days of Pliny.

The well known Pomme d'Apis or Lady Apple is historically asserted to have been brought to Rome from Peloponnesus by Appius Claudius. Dalechamps and Harduin are of opinion that it is the Petisia of Pliny, who describes it—"Odor est his Cotonearum, magnitudo quæ Claudianis, color rubens." This variety does not appear to have changed its character during this long succession of ages. In further corroboration of this, Mr Hogg, in "British Pomology," remarks, "the Pearmain, which is the oldest English apple on record, shows no symptoms of decay, neither does the Catshead, London Pippin, Winter Queening, nor any other variety—those only having been allowed to disappear from our orchards which were not worth perpetuating, and their places supplied by others infinitely superior."[1] As regards acclimation, Mr Knight's theory is proved to be equally erroneous, as we have no evidence that plants long cultivated in this country are able to withstand our winter cold better than formerly. The Dahlia, Heliotrope, and the Potatoe, are affected in the same way by frost as when they were first introduced. Mr Knight entertained the opinion, deduced, we may presume, from experiment, that more is to be expected from hybrid varieties than from the mere reproduction of old kinds; he therefore had recourse to the nice operation of dusting the pollen of one kind on the pistil of another. He opened the unexpanded blossom of the variety destined to be the female parent of the expected progeny, and, with a pair of fine-pointed scissors, cut away all the stamens, while the anthers were yet unripe, taking care to leave the style and the stigma uninjured. When the female blossom, thus prepared, came naturally to expand, the blossoms of the other variety destined to be the male parent were applied. Mr Knight has often remarked in the progeny a strong prevalence of the constitution and habits of the female parent, a circumstance confirmed by subsequent experiments.

Although the expected results are not obtained, yet cross-impregnation or hybridization is followed by certain results of immense importance in the production of improved varieties. By this means the Strawberries of the present day are so much improved, in size at least, that many of them bear little resemblance to their original parents of several generations back. The Apple, the Pear, the Peach, and the Plum, have all been so improved, but no perceptible difference has been effected in rendering them hardier than their progenitors.

The process of crossing, or even raising from seed, should nevertheless be encouraged, as it is the only means by which improved sorts are to be procured.

In the case of cross-impregnation, every seed, though taken from the same fruit, produces a different variety; and these varieties, as might be anticipated, prove to be of very various merit. In general, those seeds are to be preferred which are plump and round. An estimate of the value of the seedlings may be formed, even during the first summer of their growth, from the resemblance they bear to those of highly cultivated and approved trees. The leaves of promising seedlings improve in character, becoming thicker, rounder, and more downy every season. Those whose buds in the annual wood are full and prominent, generally prove more productive than those whose buds are small and shrunk into the bark. An early disposition to produce blossom buds, late flowering in spring, and the production of hardy blossoms, are desirable characteristics. It has been observed, that even after a seedling tree has commenced bearing, its fruit has a tendency to improve as the tree itself acquires vigour, so that, if, in the first season, there is any considerable promise, a great improvement may be expected in succeeding years.

---

[1] Professor Mohl, a German physiologist of the highest repute, thus speaks of the fallacy of Mr Knight's theory—"Thousands of experiments have shewn that the young shoots of old trees, when used as grafts, slips, &c., furnish as strong plants as the shoots of young trees. Not one single experiment speaks in favour of the opinion promulgated by Mr Knight, that all parts of a tree have a common end to their life, and that the different trees from which they have been raised from one and the same tree by grafts, decay about the same time as the parent plant."

The slowness with which seedlings reach the bearing state has been the subject of complaint among horticulturists, and indeed is the principal reason why this mode of propagation has not been more frequently practised. According to Mr Knight, the pear requires from twelve to eighteen years to reach the age of maturity; the apple from five to twelve or thirteen years; the plum and cherry four or five; the vine three or four; and the raspberry two years. The peach he found to bear in two, three, or four years. This period, however, must depend on the soil, situation, and mode of culture. In the warm and highly manured garden of M. Van Mons at Brussels (called "Pepinière de la Fidélité,") seedling pear-trees produced fruit in considerable quantities in the sixth and seventh summers. The best means of accelerating the epoch of bearing seems to be to make the trees grow vigorously when young. Crude manures are to be avoided; but vegetable earth, and, above all, a liberal supply of rotted turf, are wholesome and excellent stimulants. The seed-bed, and the ground on which the seedlings are transplanted, should be extremely well worked and comminuted with the spade; and should not be too much exposed to the parching rays of the sun, or the action of the wind. Great care ought to be taken to prevent the young plant from becoming stunted. In pruning, the small twigs in the interior should be removed, so as to relieve the tree from the bushy appearance which it frequently assumes. It has been wisely recommended to transfer scions and buds of promising individuals into other trees in a bearing state. This is peculiarly advantageous with respect to the peach and other stone fruits, as it both hastens the period of maturity, and economises the space which must be occupied on the wall.

Propagation by Cuttings.—Gooseberries, currants, figs, vines, and some others, are increased by means of cuttings. An annual shoot is taken off, along with a thin slice, or *heel*, as it is called, of the former year's wood, which is found to facilitate the production of roots. The cuttings are placed firmly in the soil, at various depths, according to their length, the buds or eyes which would thus come beneath the surface having been previously removed. Vines should in all cases be propagated from small pieces of shoots having a single bud; a shoot of an inch in length may suffice. Most of the codlin apples may be increased by cuttings; and even large branches of those which produce *burs*, may be planted at once, with success. In all deciduous trees, the operation is most advantageously performed in winter.

Propagation by Layers.—This is not much resorted to in the fruit-garden. It is occasionally employed as the means of dwarfing trees. "Laying," says Mr George Lindley, "is nothing but striking from cuttings which are still allowed to maintain their connexion with the mother plant by means of a portion at least of their stem." The operation is performed by bending down a branch to the earth, and pinning it there with pegs. A notch or slit is cut upwards, generally from the insertion of a bud. Sometimes the shoot is pierced with a number of holes; a wire is bound round it; or even a ring of bark is removed. The object of these expedients is to retard the descending sap, and thus to promote the formation of radicles, or young roots. This is also aided by bending the branch upward from the point at which the roots are wanted; and the whole branch, except a few buds at the extremity, is covered with soil. The seasons best fitted for these operations are early spring and midsummer, that is, before the sap begins to flow, and after it has completely ascended. One whole summer, sometimes two summers, must elapse before the layers will be fully rooted.

Propagation of Fruit-Trees by Grafting.—By this method apple and pear trees, sometimes plum and cherry trees, are propagated. Our attention must be directed to the *stocks* into which the shoots or scions, as they are called, are inserted; to the *scions* themselves, and to the *mechanical operations* employed in grafting.

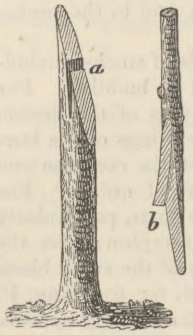
The following are the principal kinds of stocks, including, by anticipation, such as are used in budding. For *apples*, seedlings of the crab apple, layers of the doucin or paradise, and of the codlins, with cuttings of the burknot varieties. For *pears*, seedlings of the common and wilding pear; with seedlings or layers of quince. For *plums*, seedlings of any of the common sorts, particularly the muscle, the Brussels, and the Brompton; also the Bullace plum. For *cherries*, seedlings of the small black cherry or gean, Prunus Avium; and, for dwarfing, P. Mahaleb. For *apricots*, seedlings of the wilding apricot, with the muscle and Brussels plums. For *peaches* and *nectarines*, seedlings of the muscle, white pear-plum, and Damas noir plum, the almond, and the wilding peach.

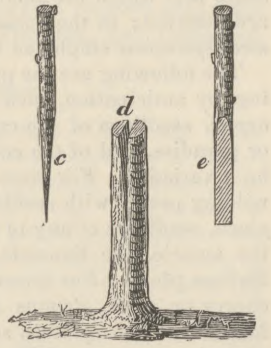
Stocks for this purpose are commonly divided into two classes, viz. *free-stocks* and *dwarfing-stocks*. The former consist of seedling plants, chiefly of the same genus or species as the trees from which the scions are taken. The latter are plants of diminutive growth, either varieties of the same species, or species of the same genus as the scion, which have a tendency to lessen the expansion of the engrafted tree. The Paradise or Doucin is the dwarfing stock for apples, the Quince for pears, the Bullace, and more recently the Sloe for plums, and Prunus Mahaleb for cherries. The nature of the soil in which the grafted trees are destined to grow, should also have weight in determining the choice of stocks. When the garden is naturally moist, it is proper to graft pears on the quince, because this plant agrees with a moist soil, and at the same time serves to check the luxuriance thereby produced. In France, peaches are commonly budded on almond stocks, to adapt them to the dry soils of that country. The seeds from which stocks are to be raised, are generally sown in beds in March; but the germination of some kinds is promoted by placing the seed, for a time, in moist sand in a greenhouse. Next season the seedlings are transplanted into nursery rows, in which they are allowed to reach the size necessary for the various forms of fruit-trees hereafter to be mentioned.

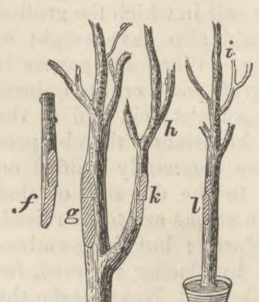
The *scion* is always a portion of the wood of the preceding year. As the diseases incident to fruit-trees are transmitted by this mode of propagation, it is desirable that the parents should be as healthy as possible. In the shy-bearing kinds it has been found beneficial to select shoots from the fruitful branches. The scions should be taken off some weeks before they are wanted, and half-buried in the earth, as it is conducive to success that the stock should, in forwardness of vegetation, be somewhat in advance of the graft. During winter, grafts may be transferred from great distances, as from America, or any part of the Continent of Europe, if carefully wrapped in hypnum moss. If they have been six weeks or two months separated from the parent plant, they should be grafted low on the stock, and the earth should be ridged up around them, leaving only one bud of the scion above ground.

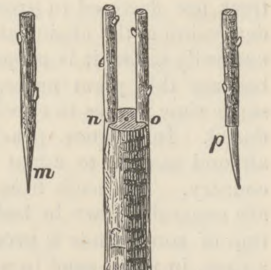
Success in *grafting* depends almost entirely on accurately applying the inner bark of the scion to the inner bark of the stock, so that the sap may pass freely from the one to the other. They are therefore fitted together, and held fast by a bandage of strips of bast matting. To lessen evaporation, a portion of ductile clay is moulded around the place of junction, and is retained until it appears, from the development of leaves, that the operation has succeeded. The best season for grafting is the month of March; but it may be commenced as soon as the sap in the stock is fairly in motion, and may be continued during the first half of April.

The most usual mode of grafting is called *whip-grafting*, or *tongue-grafting*, *a*, *b*. The top of the stock and the base of the scion are cut off obliquely at corresponding angles, as nearly as can be guessed by the eye; the tip of the stock is then cut off horizontally; next a slit is made downwards in the centre of the sloping face of the stock, and a corresponding slit upwards in the corresponding face of the scion. The tongue or upper part of this sloping base is then inserted into the cleft of the scion, and so adjusted that the inner bark may unite neatly and exactly on one side. The junction is then tied up and covered with clay. Several other methods may be mentioned, such as *Cleft-grafting*, *c*, *d*, *e*, in which the scion is sloped at the base, and inserted like a wedge into a cleft in the stock; *Side-grafting*, *f*, *g*, which resembles whip-grafting, but is performed on the side of the stock without heading it down; *Crown-grafting*, in which the scions, *m*, *p*, are inserted between the bark and the wood of the stock; *Grafting by approach* or *inarching*, resembling whip-grafting, except that the scion *h* remains attached to the parent plant, till its union at *k* and *l* with the new stock *i* be complete; when that portion of the stock above the union may be headed down, and the scion at the same time detached from the parent plant.



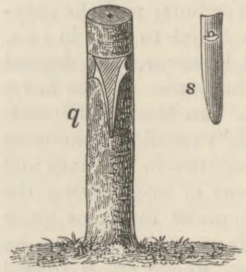


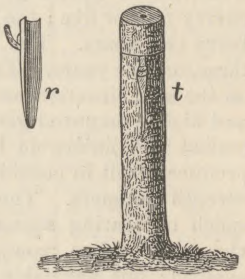




Root-grafting is performed in the modes just described, except that the scion is placed on a piece of root (as a stalk), of proper thickness, and with fibres and fibrils attached to it. In the most unfavourable soils, some sorts of fruit-trees thrive better than others; and it has been suggested, that by using root-stocks of such flourishing trees, and grafting other desirable kinds on them, canker may often be avoided, and the better kinds of fruit produced.

Propagation by Budding.—Most kinds of fruit-trees may be propagated by budding; and there are some, such as peaches and apricots, which can scarcely be multiplied in any other manner. It consists in removing a bud with a portion of the bark from one tree, and inserting it in a slit of the bark of another tree. The season for performing this operation is in July or August, when the buds destined for the following year are completely formed in the axils of the leaves, and when the portion of bark parts freely from the wood beneath. The buds to be preferred are those on the middle of a young shoot. There are many forms of budding, but that which is simplest, and is generally practised in this country, called *Shield-budding*, may alone be described. The operator should be provided with a budding-knife, in which the cutting edge of the blade is rounded off at the point, and which has a thin ivory or bone handle, like a paper-folder, for raising the bark of the stock. A horizontal or transverse incision is made in the bark quite down to the wood, and from this incision a perpendicular slit is drawn downwards, to the extent of perhaps an inch. The slit has now a resemblance to the letter T as at *q*; a bud is then cut from the tree intended to be propagated, having a portion of the wood attached to it, so that the whole may be an inch and a half long, as at *s*. The bit of wood is then gently withdrawn, care being taken that the bud adhere wholly to the bark or shield, as it is called, as at *r*, which is the reverse of *s*. The bark on each side of the perpendicular slit being cautiously opened with the handle of the knife, the bud and shield are inserted, as at *t*. The upper tip of the shield is cut off horizontally, and brought nearly to fit the bark of the stock at the transverse incision. Slight ties of moist bast-matting are then applied. In about a month or six weeks the ligatures may be taken away, when, if the operation has been successful, the bud will be fresh and full, and the shield firmly united to the wood. Next spring a strong shoot is thrown out, and to this the stock is headed down in the course of the summer.





PLANTING FRUIT-TREES.

In transferring the young trees to those places, whether in the open border or against the wall, where they are to remain, it is important that the situations should be carefully selected; adapting the trees to sites suitable in respect of soil, shelter, and aspect. The trees should be cautiously lifted from the nursery lines, all mutilation or bruising of the roots being carefully guarded against; and, to prevent the desiccation of the fibres, they should be planted as soon as possible after being lifted. When they have to be carried to a distance, the roots should be enveloped in damp hypnum-moss. In the ground, which is presumed to have been previously trenched or otherwise prepared, pits or holes are formed, and the soil is finely pulverized; and in these the trees are placed, their roots being spread out and intermingled with the earth. Shallow planting is strongly recommended, two or three inches of soil being in general a sufficient covering. The doucin or French paradise stocks are preferable for this reason, that they throw out delicate fibres which readily spread along the surface, instead of bundles of hard roots which generally characterize crab stocks. On filling up the hole, a surface of at least an equal size is *mulched*, that is, covered with dung or litter, so as to restrain evaporation, and preserve moisture. In the case of wall-trees, a space of five or six inches is usually left between the stem at the insertion of the roots and the wall, to allow for the effects of growth. Young standard trees are tied to stakes, to prevent their roots being ruptured by the wind-waving of the stems. During the dry weather of the first summer, the trees should be watered from time to time as occasion may require.

The selection and distribution of the different kinds of fruit-trees is an important and interesting point in the formation of a garden. Regard must necessarily be had to local situation and climate, as the selection ought manifestly to be different for a garden in the south-west of England, and for one in Yorkshire or in Scotland; for one near the level of the sea, and for another elevated several hundred feet above it. The best walls, having a south or south-east aspect, are devoted to the grape-vine, the fig-tree, the peach and apricot. The finer varieties of French and Flemish pears require and deserve a good aspect, as also the early sorts of cherries. The later cherries, and the generality of plums, succeed very well either on an east or west aspect. In Scotland, the mulberry requires the protection of a wall, and several of the finer apples do not arrive at perfection without it.

The wall-trees intended to be permanent are called *dwarfs*, from their being grafted near the ground. Between each of these, trees with tall stems, called *riders* in Scotland, and standards in England, are planted as temporary occupants of the upper part of the wall. The riders should always be five or six years trained in the nursery, in order that when planted out they may come into bearing as speedily as possible. The distances at which the permanent trees are planted is to be regulated by the known growth of the different sorts, and by the height of the wall. When the walls are about twelve feet high, the following average distances have been recommended:—For vines, 10 or 12 feet; peach and nectarine trees, from 15 to 20 feet; fig-trees, 20 feet at least; apricots, from 15 to 24 feet; plums and cherries, from 15 to 20 feet; pear-trees, 20 feet if on quince stocks, and 30 feet on free stocks; apple-trees, 12 feet if on paradise stocks, and 15 to 25 feet on free stocks. Where the walls are only seven or eight feet high, the distance should be increased by nearly one-fourth, as in this case the want of height must be compensated by greater breadth.

Apples and pears make the best espalier-rail trees. These should be of the more robust sorts, and should be planted at the distance of 15 or 20 feet. Cherries and plums are sometimes introduced into the espalier-rail row, but succeed only where they would do equally well or better as standards.

In many small gardens, dwarf standards are preferred to espalier-rail trees. They are placed along the inner borders at 8 or 10 feet apart. When proper attention is paid to such trees, the effect is very pleasing, each being in itself a handsome object, and generally clothed with fine fruit. Where the situation is warm, and the climate favourable, a few of the finer pears which have hardy blossoms should be planted out in this form. Though they may fail to ripen in some seasons, they will often add greatly to the resources of the fruit-room, their produce being frequently superior in flavour to the fruit grown on walls.

Training.—Two functions belong to training,—that, namely, which modifies the form of the tree, and that which regulates the bearing wood, and consequently the supply of blossom. The latter, more accurately termed *pruning*, being of a varied character, will more properly fall to be considered when treating of the several fruits; at present we shall make a few remarks on the former. The essential properties of training are, that it should be simple, not requiring frequent amputation; that it should be appropriate to the growth of the tree; and that it should be such as to facilitate the production of fruit. The knife is the great instrument in training, and whoever can wield it skilfully, will have a perfect command over his trees: at the same time, it may be laid down as a maxim, that it should be used with some degree of reserve, as nothing is more prejudicial to the health and fruitfulness of all sorts of fruit-trees, than severe and injudicious cutting.

Training of Standards.—Orchard-trees are generally worked in the nurseries with stems five or six feet high. All that is necessary, in pruning trees of this sort, is merely to cut out the branches which cross or press upon one another. Bushy heads should be thinned out, and those which are too lax cut back. Three or four leading branches may be selected, to pass ere long into boughs, and form a handsome skeleton for the tree; but it is useless to be finical in this matter, as these branches will soon grow beyond the power of the pruner, and of any artificial system which he may adopt. Dwarf standards being more accessible, are more under the dominion of training. When worked on paradise stocks, they may be kept not much superior in size to gooseberry bushes, and in a state of abundant fruitfulness. The more fanciful Dutch modes of training apple-trees, in the cup-and-ball fashion, and after many other curious devices, have never been relished in Britain. In this country, they are generally allowed to grow *en buisson*, that is, as bushes. For pears, the French forms, *en pyramide*, fig. 2, and *en quenouille*, fig. 3, are in most esteem.

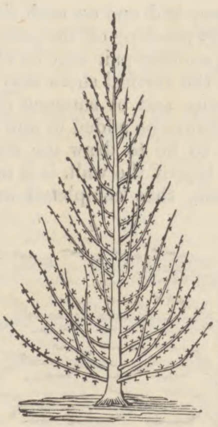


Fig. 2.

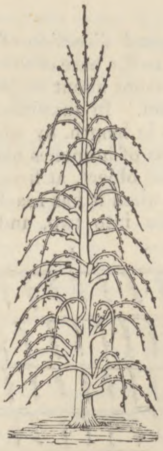

Fig. 3.

Training of Wall-Trees.—A fruit-tree planted against a wall is evidently in a constrained and artificial situation, from which it makes continual efforts to escape. Much attention is necessary to repress this tendency, which, were it permitted to act, would disfigure the tree, and neutralize the advantages of a wall, without imparting in

Fruit Garden.

their place the freedom of a standard in the open air. To be successful, the operator should be acquainted with the theory of vegetation, should study the mode of growth in different trees, and, above all, remember the purpose of all training, viz. the production of bearing wood.

One great difficulty is to preserve equilibrium in the growth of the several parts of the same tree; for the attainment of this object, excellent hints are to be found in the *Pomone Française*. A shoot will grow more vigorously whilst waving in the air than when nailed close to the wall; a weak shoot should therefore be left free, whilst its stronger antagonist should be restrained. A shoot diverging slightly from the perpendicular, will, other things being equal, obtain a more copious supply of sap than one that is laid out horizontally, or is deflected downwards. A luxuriant shoot may be retarded for some time by having its tender extremity pinched off, and may thus allow a weaker brother to overtake it. By these and other expedients, which will suggest themselves to an attentive horticulturist, and by the prudent use of the knife, it will be easy to execute the following forms, which, on account of their simplicity and general excellence, we select out of many to be found detailed in works on gardening.

The *horizontal* form (fig. 4.) has long been a favourite in this country. There is one principal ascending stem, from which the branches depart at right-angles, at intervals of ten inches or a foot. In trees of ordinary vigour the vertical shoot is cut back every winter to within fourteen inches of the highest pair of branches: a number of shoots are produced in the beginning of each summer, out of which three are selected: one is trained in the original direction of the stem, and one on each side of it parallel to the base of the wall. By pinching off the point of the leading shoot about midsummer, another pair may be obtained in autumn. In luxuriant trees, the vertical shoot may be left two feet in length, by which means, and by summer pruning, four pairs of branches may sometimes be added in one season. The great object, at first, ought to be to draw the stem upwards: when it has reached the top of the wall, it is made to divaricate into two, and the tree, thus completed as to its height, is henceforth suffered to increase in breadth only.

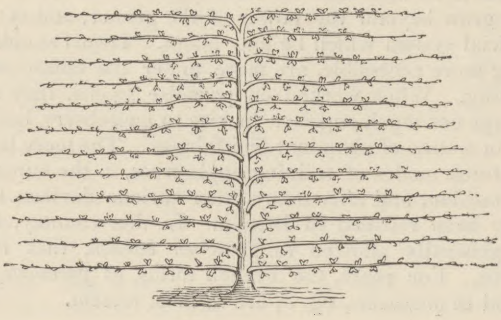

Fig. 4.

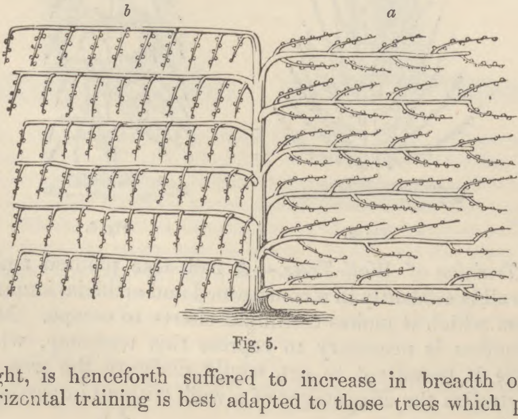

Fig. 5.

Horizontal training is best adapted to those trees which produce strong shoots, as the Ribston Pippin apple, or the Jargonelle pear. For the more twiggy kinds, the form represented in fig. 5 is more suitable. In this the horizontal branches are eighteen or twenty inches distant, and the small shoots are trained in between them, either on both sides, as below letter *a* in the figure, or on the under side and downwards, as below *b*. This last is an excellent method of reclaiming neglected trees of this description. Every alternate branch being taken away, and the spurs cut off, the young shoots are trained in, and soon produce good fruit. It is rather singular that the late M. Thouin, in his account of the *Ecole d'Horticulture pratique du Muséum*, classes the horizontal form among *les tailles hêtéroclites*, and says, that, in consequence of its invariably producing a *tête de saule*, that is, a hedge of young shoots at the top, it has been long since abandoned. From this remark, we cannot help drawing the conclusion, that in France the theory of training must be in advance of the practice.

Fruit Garden.

The other principal form is called *fan*-training. In this there is no leading stem, and the branches are arranged somewhat like the spokes of a fan. Fig. 6 represents this shape as it commonly occurs in gardens. In the case of apple and pear trees, this mode, though frequently adopted, is not superior, perhaps not even equal, to the horizontal configuration: it is evident, that when the branches reach the top of the wall, where they must be cut short, a *tête de saule* is inevitable. It would be better to adopt a modification of the fan shape used for stone fruits (fig. 7); to establish a certain number of mother branches, and on these to form a series of subordinate members, chiefly composed of bearing wood. The mother branches or limbs should not be numerous, but well marked, equal in strength, and regularly disposed. The side branches should be pretty abundant, short, and not so vigorous as to rival the leading members. To ensure regularity, training should commence with maiden plants, or such as have only one year's growth from the graft; leaders of equal strength should be selected, and encouraged to grow out longitudinally as much as possible, and all crowding among the inferior shoots should be prevented. In *riders* this form passes into the stellar arrangement. The French have made considerable improvements in this mode of training, some of which will be noticed when we come to treat of the training of the Peach.

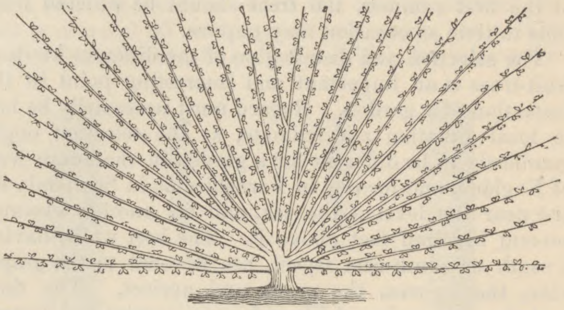

Fig. 6.

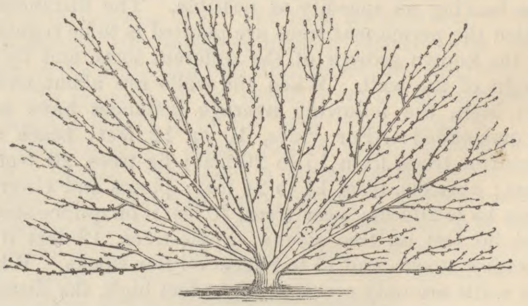

Fig. 7.

Intermediate between horizontal and fan training, is the *half-fan*. It is nearly allied to the horizontal form, but the branches form an acute angle with the stem, and this disposition is supposed to favour the equal distribution of the sap. In the winter pruning, three and sometimes four central branches are cut back; the shoots which arise from these are arranged in the fan order, and, as they elongate, are gradually brought into the horizontal position. The tree is finished at top as in the horizontal form. Sometimes, as in fig. 8, two vertical stems are adopted. For vigorous trees, this figure seems to combine the advantages of both the foregoing.

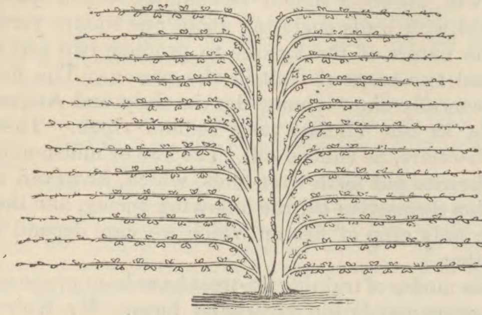

Fig. 8.

The choice of particular modes of training is too often determined by mere fashionable prejudice, which leads to the application of the same form to all sorts of trees. Thus the French are apt to reduce every thing to the *fan* system, while some English horticulturists are inclined to force trees of the most rambling growth into the pillory of a *horizontal* arrangement. Such a uniformity cannot possibly be in accordance with nature. The enlightened cultivator will employ various forms, and will determine for himself which is the most appropriate, not only for every species, but even for each particular variety of fruit-tree. By attentive observation and rational experiment, more knowledge in this department may be attained in a few years, than by a whole life spent in routine practice.

Of the expedients for inducing a state of fruitfulness in trees, the most common is the cutting back of the roots to within three or four feet of the stem; an operation which is generally found efficacious, when barrenness proceeds from over-luxuriance and too copious a supply of sap. To attain the same end, recourse is sometimes had to *ringing* the branches or stem, that is, removing a narrow annular portion of the bark. The trees, it is said, are thereby not only rendered productive, but the quality of the fruit is at the same time apparently improved. The advantage is considered as depending on the obstruction given to the descent of the sap, it being thus more copiously afforded, in its elaborated state, for the supply of the buds. The ring should therefore be made in spring, and of such a width that the bark may remain separated for the season. It ought to be observed, however, that none of the stoned fruit-trees are benefited by ringing. The operation, however, is a species of mutilation, rendered unnecessary by judicious root pruning. Sometimes barrenness proceeds from defect of climate and poverty of soil; in which case, a warmer situation and more generous treatment are the most effectual remedies. Fruit-trees should never, if possible, be allowed to become stunted; for in this state they produce only worthless fruit, and acquire a habit which scarcely admits of amelioration.

Protection of Blossom.—In our variable climate, and particularly in the northern and eastern parts of the island, it is very desirable that the horticulturist should be provided with the means of defending the blossom of his fruit-trees from the late frosts in spring. Some recommend frames covered with bunting, osnaburg, or similar light fabrics, set in a sloping position in front of the trees. The best protection for wall trees are portable wooden copings, about nine inches in breadth, fixed to permanent iron brackets placed in the wall immediately under the stone coping. These wooden protectors should be put on during spring before the blossom buds begin to expand, and to them should be attached scrim cloth (a sort of very thin canvas), admitting light pretty freely, yet of itself sufficient to ward off our ordinary frosts. This canvas to be let down towards evening, and drawn up again in the morning. Any contrivance that serves to interrupt radiation, though it may not keep the temperature much above freezing, will be found sufficient. Standard fruit-trees must be left to their fate, and, indeed, from the lateness of their flowering, they are generally more injured by blight, and by drenching rains, which wash away the pollen of the flowers, than by the direct effects of cold.

CULTURE OF HARDY FRUITS.

We now proceed to the more special culture of the inmates of a British fruit-garden. We shall begin with the more tender, but for details regarding these, we must, to a considerable extent, refer to the forcing department, in which alone many of the finer fruits can be perfected. We will confine our lists of fruits to selections from the very best kinds in cultivation. Those who are curious in this department of pomology, may further consult the "Fruit Catalogue of the London Hort. Soc.," "The Book of the Garden;" for American fruits, "Downing's Fruits and Fruit-trees of America;" for apples alone, "Hogg's British Pomology;" and for coloured representations, the "Pomological Magazine," and "Pyrus Malus Brentfordensis." The recently established "Pomological Society of London" will hereafter be the medium through which information will be gained of all that is interesting regarding the nomenclature and merits of new fruits.

The Grape Vine (*Vitis vinifera*) can scarcely be said to be a hardy fruit in our climate. In every case it requires a good aspect; and north of York, a crop of *dessert* grapes cannot be expected without the aid of a hot wall. In the extreme south-west districts of England, indeed, grapes fit for the manufacture of wine, perhaps equal in quality to those in the north of France, might be produced on dwarf standards; and there is abundant historical evidence that productive vineyards once existed in that part of the country.

In the Lond. Hort. Soc. Catalogue, 197 varieties of grapes are enumerated. Some of these, however, have not as yet been well ascertained; some are pronounced indifferent, and others worthless. We shall name only a few of those most deserving the attention of the cultivator.

Black Damascus. Bunches large, with round berries and sweet juice. This valuable late variety does not set well, and the bunches are improved by the blossom being dusted with the pollen of some hardy kind.

Frontignan (or *Frontignac*). Five varieties under this appellation, and distinguished by the names of *black, blue, grizzly, red,* and *white,* are mentioned in horticultural catalogues. They vary in colour and form of the cluster. The berries are round, the skin thick, and the juice of a rich muscat flavour. They are all of the highest excellence.

Black Hamburgh. This is a well-known grape, of great value, and perhaps more generally cultivated for the dessert in this country than any other sort. It ought to be in every collection. Of this excellent grape there has long existed seminal varieties, and late years have added to their number the following, viz.:—Wilmot's Black Hamburgh; Black Prince Hamburgh; Pope's Hamburgh; Judson's Richmond Villa Hamburgh; Mill Hill Hamburgh; and more recently a white variety said to be a hybrid between the muscat of Alexandria and Black Hamburgh.

Black Lombardy (or *West's St. Peter's.*) Bunches large, berries round, skin thin, with a sweet flavour; an excellent late sort. The fruit will hang on the vines till March.

Chasselas Musqué. Bunches medium size, long and loose, berries globular, yellowish when ripe, and apt to crack if grown in too damp an atmosphere; one of our very best grapes.

Royal Muscadine, L. Hort. Cat. or *White Muscadine* of Lindley. Usual Chasselas of Paris. This, though not a first rate grape, is a favourite with many. Bunches large, berries white, round, with sweet flavour.

Muscat of Alexandria. Bunches long, berries white and oval, with a delicious muscat flavour. This most admirable variety requires a high temperature, and should properly have a small vinery for itself.

White Sweet Water. Bunch loose, berries round, flavour sweet. It ripens early, generally from the middle to the end of September; and in the south of England it succeeds against the open wall.

The bunches should be allowed to hang until they are perfectly ripe, when the berries acquire a slight russet colour. It has long been a favourite grape.

Nice, or *White Nice*. Bunches extremely large, berries medium size, greenish white, globular. Habit robust, foliage large and downy underneath, keeps long after ripening.

Stillward's Sweetwater, or *Chasselas précoce*. It is desirable for earliness, and the bunches possess the property of keeping good on the plant for two or three months after the berries are ripe.

Trebbiana, a comparatively new grape, somewhat resembling the Tokay, esteemed for its keeping long after ripening.

The *Black Prince* is of easy cultivation, and the berries are of a pleasant flavour.

The *Verdelho* has loose bunches, berries of a greenish-yellow colour, small, oval, numerous; when fully ripe, of a rich saccharine flavour. It is the principal grape cultivated in Madeira for making the celebrated wine of that island.

Barbarossa. Of this kind there are a black and a white variety, both recently introduced and esteemed for their properties of long keeping.

The *Esperione*, or *Turner's Early Black*, has the bunches large and shouldered, not unlike those of the Black Hamburgh. The berries are of a fine dark colour, with a bluish farina or bloom; the pulp adheres to the skin; and though neither highly flavoured nor melting, it is very pleasant. This grape ripens on the open wall near London.

The *Syrian Grape* is remarkable only for the extraordinary size and beauty of its bunches; it is a late variety, and the berries are sweet and not without flavour, when properly ripened; but, in general, it is a worthless variety.

For an ordinary vinery the following may be recommended:—Black Hamburgh, Black Tripoli, Chasselas musqué, Stillward's Sweetwater, Royal Muscadine, White Frontignan, and Black Lombardy. For a stove or late vinery may be particularized the Grizzly Frontignan, Black Tripoli, Muscat of Alexandria, Canonhall Muscat, Barbarossa black and white, Hamburgh, Nice, and Chasselas musqué. For training against the rafters of a greenhouse, the Black Prince, Verdelho, Esperione, and Black Cluster, are among the best.

The kinds commonly grown against the open wall in England are the Miller Burgundy, Esperione, White Muscadine, White Sweetwater, Early Black, Grove-End, and Pitmaston White Cluster. In the north of England, and in the south of Scotland, vines always require hot walls. Vine culture on the open wall, in this country, can never be calculated upon with any degree of certainty.

THE FIG.

The Fig-Tree (*Ficus Carica*) is not generally a favourite in this country. Every good garden ought, however, to contain a few trees to furnish a supply during the natural season. The foliage of the tree is large and elegant, and the mode of fructification is curious: the pulpy part, which we call the fruit, being, in fact, a common receptacle, and the anthers and stigmata being produced inside.

The following are the most esteemed:—Angelique, Brunswick, Large White Genoa, Black, White, and Brown Ischias, Malta, Lee's Perpetual, Marseilles, Nerii, Brown Turkey, and Pregussata.

Of these, the Marseilles, the Black Ischia, Lee's Perpetual, and Brown Turkey, are the best adapted for forcing; the others are suitable for walls.

Fig-trees should be propagated by cuttings put into flower-pots, and placed in a gentle hotbed. They are, however, most speedily obtained from layers. The shoots laid down should be two or three years old; and these, when rooted, will form plants ready to bear fruit the first or second year after planting. Suckers ought never to be used.

In some places in England fig-trees are planted out as standards; and in Kent and Sussex a few small fig orchards exist. In Scotland a south wall is indispensable, but if this is procured in a good situation, and when the trees are old enough, they bear remarkably well. The best soil for a fig border is a rich friable loam, on a subsoil not retentive of moisture, or which has been effectually drained. To correct the over-luxuriance of their growth, the roots should be confined within spaces surrounded with walls enclosing about one square yard.

It is the nature of the fig-tree to produce two sets of shoots, and two crops of fruit in the season. The first shoots generally shew young figs in July and August, but these in our climate very seldom ripen. These should, therefore, be rubbed off. The late or midsummer shoots likewise put forth fruit-buds, which, however, do not develop themselves till the following spring, and then form the only crop of figs on which we can depend in this country.

Various modes of training fig-trees have been proposed. Lindley recommends the horizontal form. Mr Knight carried up a central stem perpendicularly to the top of the wall, and then radiated the side-branches horizontally and pendently, in close contact with the wall. Luxuriance of growth is supposed thus to be checked, and the branches thrown into a bearing habit. Root-pruning and walling-in the roots have more effect in inducing fruitfulness than any other sort of pruning.

The Rev. G. Swayne in recommending rubbing off all the young figs which appear in autumn on shoots of the same year, observes that for every young fig thus displaced, the rudiments of one or perhaps two others are formed before winter, and developed in the following year.

The winter dressing of the fig-tree takes place immediately after the fall of the leaf. The immature figs which may remain are removed, irregularities are corrected, and the shoots nailed neatly to the wall. Various modes of protecting the branches during winter have been adopted. Mr Swayne mentions that he wraps up the young shoots with waste paper. Mr Forsyth recommends covering wall fig-trees with the spray of laurel or yew, and then tucking in short grass or moss (*hypnum*) among the spray.

Sir Charles Monck states that the same fig-tree seldom produces fruit containing both perfect stamens and pistils, and conjectures that this is the cause of the fruit being so often prematurely shed. *Caprification*, or assisting the fructifying and maturation of figs, has often been sneered at; but here we see the propriety of that kind of it which consists of hanging or shaking the branches of the wild fig (*caprificus*) over the cultivated tree at the time when both were in blossom.

The Peach (*Amygdalus persica*) is a stone-fruit of oriental origin, said to have been brought from Persia by the Romans, about the beginning of the empire; but the precise period of its introduction into our gardens, of which it has long been the pride and ornament, is not well ascertained. There are two principal varieties: the Peach, properly so called, with a downy skin; and the Nectarine, with a smooth skin. These, following the authority of Linnæus, we consider as one species; and as their culture is precisely the same, we shall speak of them as distinct only when referring to their sub-varieties. Each of these varieties is again divided by gardeners into *freestones* or *pêches*, and *clingstones* or *pavies*, according as the stone parts freely from the pulp, or adheres to it. We shall here treat chiefly of the freestones, as being most hardy, and fittest for the open wall in Britain.

Mr George Lindley, whose arrangement is the best that has hitherto been published, enumerates 60 kinds of peaches and 28 of nectarines. In the Horticultural Catalogue, the names of 183 peaches and of 65 nectarines are recorded. We shall notice only a few of those which are most distinct, and best adapted to our climate.

Fruit Garden.

Peaches.

Red Nutmeg, or *Avant rouge*. This is one of the earliest peaches, ripening about the beginning of August. The fruit small; colour pale yellow towards the wall, bright vermilion next the sun; pulp white, but red at the core; the juice rich and musky. The tree is an abundant bearer.

Acton Scot. This was raised by Mr Knight between the noblesse and the nutmeg peach, in 1814. The fruit is red next the sun, and white on the other side; the pulp rich, juicy, and saccharine; the tree is a good bearer, and not apt to be affected with mildew. It ripens in August.

Spring-Grove. This is another of Mr Knight's peaches, raised from the grosse mignonne crossed with the pollen of the nutmeg. It is dark red on one side, and bright yellow on the other; pulp firm, but melting, and of excellent flavour. The tree is a good bearer, but succeeds best on an apricot stock. The fruit ripens in the beginning of September.

Grosse Mignonne. Fruit large; skin pale yellow, and deep purple next the sun; flesh melting; juice plentiful, and of delicious flavour. This excellent peach is a good bearer, and forces well, but the fruit does not bear carriage. It ripens in the end of August and beginning of September.

Madeleine de Courson; Red Magdalene of Miller. Blossoms large; fruit rather below the middle size; colour yellowish white next the wall, beautiful red next the sun; flesh white, with very little red at the stone; juice rich and vinous. Tree a good bearer; fruit ripening about the beginning of September. "An excellent peach," says Mr. Lindley, "and ought to be found in every collection."

Royal George. This is a well-known peach, much cultivated. By nurserymen it is often given out as the Red Magdalene; but it is at once distinguished from the Red Magdalene of Miller, by the blossoms being small. Against a good wall it ripens in the beginning of September, even in indifferent seasons. Fruit large, purplish red next the sun, whitish where shaded; flesh white, varied with red next the stone, which is free; melting, rich, with an abundant sugary juice. It is also one of the best kinds for a peach-house, fruiting freely, and ripening well. The foliage is, however, rather subject to mildew.

Noblesse. This has long and deservedly been a favourite in our gardens. It is a very large fruit; the skin pale red when ripe, the flesh juicy and rich. The tree is a good bearer, and the fruit ripens in September.

Bellegarde; the *Galande* of the nurseries. Fruit large and globular; skin deep red, with purple streaks on the sunny side; flesh pale yellow, very melting; juice rich. An excellent peach; the tree forces well, and the fruit ripens on the open wall about the middle of September.

Late Admirable, or *La Royale*. Fruit large; skin pale green next the wall, pale red on the sunny side; flesh greenish white, red at the stone; juice abundant, and, when well ripened, of a high flavour. "One of the very best late peaches," says Mr Thomson, "and ought to be in every collection; it is very proper for the peach-house, to succeed the earlier sorts."

Nearly allied to the preceding is the *Teton de Venus*, a beautiful fruit, but requiring a warm situation. In a good season, it ripens at the end of September; is saccharine, and at same time of fine flavour.

Among other excellent peaches may be mentioned:—*Freestones*, Barrington, Chancellor, Knight's Early, Downton Early, Malta, Morrisania Pound, Royal Charlotte, Royal George Mignonne, William's Early Purple, Early Admirable, Alberge, Late Warburton, and Petite Mignonne; *Clingstones*, Catherine, Heath, and Old Newington.

Nectarines.

Fairchild's Early. A beautiful little freestone, chiefly, however, cultivated for its earliness. It ripens about the middle of August.

Elruge is an excellent fruit of a moderate size; flesh white, almost to the stone, which is free. The tree forces well, and is a good bearer. Fruit ripens about the beginning of September. The best sort grown.

Hunt's Tawny. Size moderate; skin pale orange next the wall, russet-red towards the sun; flesh deep orange, juicy, and well-flavoured; a freestone. A very distinct sort, worthy of cultivation for its earliness.

Early Newington. A fine large clingstone; pale green on the shaded side, bright red next the sun; juice saccharine and well-flavoured. Ripens in August.

Red Roman. An excellent old clingstone, now seldom to be found genuine, but worthy of re-introduction.

A few other first-rate nectarines may be enumerated:—*Freestones*, Brinion, Downton, Murrey (*i. e.*, murrey-coloured), Pitmaston Orange, Violette grosse, Violette hâtive, Duc de Tello, Hardwick Seedling, New White. The Barker and the Stanwick nectarines are very recent acquisitions, and are natives of Syria. *Clingstones*, Imperatrice, Newington Tawny. The above sorts are equally suited for open air culture or for forcing, with the exception of the last.

Fruit Garden.

To perpetuate and multiply valuable varieties, peaches and nectarines are budded upon plum or almond stocks. For dry situations, almond stocks are preferable; and for damp or clayey loams, it is better to use plums. An almond budded on a plum stock may be rebudded with a tender peach, greatly to the advantage of the latter. The peach border should be composed of turfy mellow loam, such as is suitable for the vine and the fig, put in as rough as possible, or not broken small and fine. It should be vaulted to render it free from latent dampness. It need not be of greater depth than eighteen inches; for the peach-tree thrives best, and is most productive, when the roots are near the surface of the ground. We believe that in many instances, all that is required to remedy sickly and unfruitful trees is to bring up their roots within five or six inches of the surface. In this country nothing is a greater obstacle to success in peach culture than trenching the borders, and cropping them heavily with culinary vegetables.

The fruit of the peach is produced on the twiggy shoots of the preceding year. If these be too luxuriant they yield nothing but leaves; and if too weak, they are incapable of maturing the fruit. To furnish these, then, in sufficient abundance, and of requisite strength, is the great object of peach training and pruning. All twiggy trees naturally fall into the fan form; and, accordingly, this has generally been adopted in the culture of peaches.

We shall first, therefore, notice the old English method, and then briefly the French, and other new modes of training.

The *old fan* form is very nearly that already given (fig. 6) as a specimen of fan training for twiggy trees. The young tree is often procured when it has been trained for two or three years in the nursery; but it is generally better to commence with a *maiden* plant, that is, in the first year after it has been budded. It is then in ordinary practice headed down to five or six buds, and in the following summer two to four shoots, according to the vigour of the plant, are trained in; the laterals also being thinned out, and properly nailed to the walls. Suppose there are four branches; in the subsequent winter the two central ones are shortened back to produce others, and the inferior ones are laid in nearly at full length. In the following season additional shoots are sent forth; and the process is repeated till eight or ten principal limbs or *mother branches* are obtained, forming, as it were, the framework of the future tree. These mother branches are occasionally raised or depressed, so as to maintain their equilibrium, and are as much encouraged to grow outwards as is consistent with the regular filling up of the tree. The laterals are carefully thinned out (by pinching off with the fingers) in summer, and the remainder are nailed in, to afford subordinate members and bearing wood. When the centre of the tree has been filled up, all the training necessary is merely to prevent the inferior members from acquiring an undue ascendancy over the mother branches. It is highly advantageous to have abundant space, and to draw the tree outwards, so as to render it thin, without being anywhere destitute of young shoots.

Meanwhile the pruning for fruit has been going on. This consists in shortening down the laterals which had been nailed in at the disbudding, or summer pruning. Their length will depend on their individual vigour, and the luxuriance of the tree. The buds, which are generally double, or rather two together, with a fruit bud between them, seldom occur quite close to the insertion of the shoot. Perhaps two or three pairs are left with a wood bud at the point to afford a growing shoot, in order to act as its lungs: for it is necessary that there should be leaves above the fruit. The extent to which the fruit is thinned must depend on the vigour of the tree; a pair of fruit to each square foot of wall being an average allowance. When the fruit begins to swell, the point of this leading shoot is pinched off, that it may not drain away the sap. Any young shoot from the wood-eyes at the base of the bearing branch is carefully preserved, and in the following winter it takes the place of the branch which has borne fruit, and is cut out. If there be no young shoot below, and the bearing branch is short, the shoots at the point of the latter are pruned for fruit; but this must be done cautiously; and if the bearing branch be long, it is better to cut it back for young wood. It is the neglect of this which constitutes the principal error of the English fan system as it is usually practised. Several times during summer the trees ought to be regularly examined; the young shoots respectively to be topped and thinned out; those that remain to be nailed to the wall, or braced in with pieces of peeled willow, and the whole trees ought occasionally to be washed with the force-pump.

The *Montrueil form* is represented by fig. 9. The principal feature is that which constitutes the great principle of all French training, viz., the suppression of the direct channel of the sap. Four, more commonly two, *mère branches* are so laid to the wall that the central angle contains about 90°. The other branches are all treated as subordinate members. This form is open to the objection, that if the under branch should die, the upper one cannot be brought down into its place.

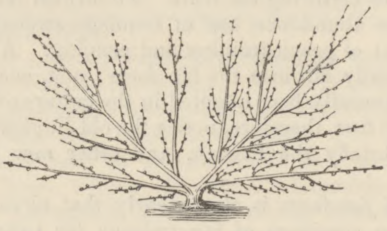

Fig. 9.

The form *à la Dumoutier* (so called from its inventor, and described at great length by Lelieur), is merely a refinement on the Montrueil method. It will be sufficient to mention to the experienced trainer (and none other can be expected to execute this form), that the formation of the tree commences with the inferior limbs and proceeds towards the centre, the branches being lowered from time to time, as the tree acquires strength. What is most worthy of notice in this method, is the management of the subordinates in the pruning for fruit. When a shoot promises blossom, it is generally at some distance from the point of insertion into the old wood, and the intermediate space is covered with wood buds. All the latter, therefore, which are between the old wood *a* and the blossom *c*, in the outer figure, except the lowest *b*, are carefully removed by *ebourgeonnement*. This never fails to produce a shoot *b* in the inner figure, the growth of which is favoured by destroying the useless spray above the blossoms, and pinching off the points of those which are necessary to perfect the fruit. A replacing shoot is thus obtained, to which the whole is invariably shortened at the end of the year. The branch thus treated is called the *branche de reserve*.

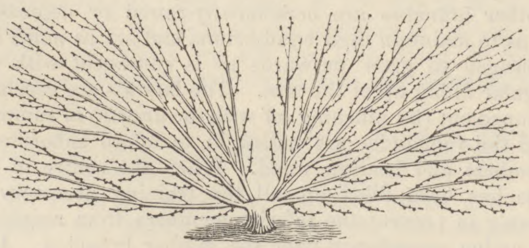

Fig. 10.

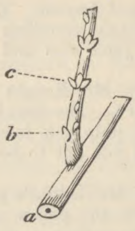

Fig. 11.

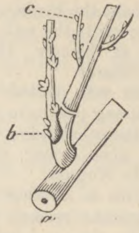

Fig. 12.

The form *à la Sieulle* is another modification of the Montrueil training, of which fig. 13 will give a general idea. The two mother branches are laid in very obliquely, and are never shortened. On the subordinate branches only three buds are left at the winter pruning, one terminal, and two at a considerable distance from each other on the sides of the shoot. This method is not well adapted to our climate.

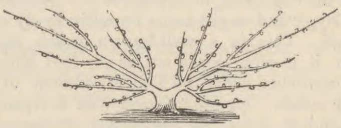

Fig. 13.

Mr Seymour's form approaches more nearly to the French methods than any other practised in this country. It will be seen, however, from the annexed figure (fig. 14), that he does not suppress the direct channel of the sap. This circumstance, although considerable stress seems to be laid upon it, is not essential to the plan, nor is perhaps the best part of it. The principal novelty is, that the bearing shoots are all on the upper sides of the mother branches, and that these bearing shoots are wholly reproduced once a-year. The one side of this figure represents the tree *after* the winter pruning, the other side before it has undergone that operation. It will be observed that on this latter side there are pairs of shoots on the upper parts of the mother branches. The lower shoot, that, namely, which has borne fruit, is cut out, and the other is brought down into its place. This replacing shoot is shortened to about eight or nine inches, care being taken to cut at a wood-bud; and at the time of disbudding, the best situate buds, together with those nearest the base, are left for the future year's bearing. To this plan it has been objected that the annual excision of the bearing shoots produces a series of rugged and increasingly ugly protuberances at their base and along the upper

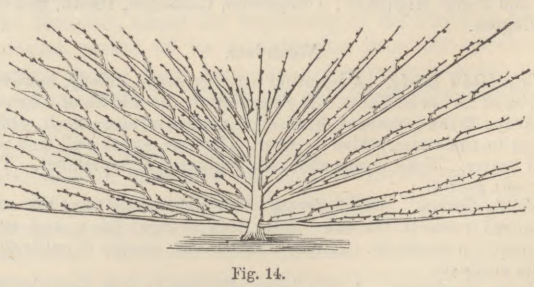

Fig. 14.

surface of the principal members; an objection which also militates against Dumontier's form. Others, on the other hand, declare that Mr Seymour's mode is the most perfect in theory that has been described. For ourselves, we are inclined to prefer the old fan form, when well executed, as nearest the natural habit of the tree, and as best adapted to our uncertain climate. In the training of peaches, "whatever is best administered is best;" and there is no doubt that many ingenious gardeners have only partial success, because, from the multiplicity of their engagements, their trees can receive only partial attention.

For cold and late situations, Mr Knight has very judiciously recommended the encouraging of spurs on the young wood, as such spurs, when close to the wall, generate the best organized and most vigorous blossoms, and ensure a crop of fruit. They may be produced, by taking care, during the summer pruning or disbudding, to preserve a number of the little shoots emitted by the yearly wood, only pinching off the minute succulent points. On the spurs thus procured, numerous blossom-buds form early in the following season. This practice is well adapted to cold situations.

Peach-trees, particularly in the north of England, and also in Scotland, require protection from atmospherical influences, especially at the period of blossoming. Canvass or bunting screens are most effectual. If the protecting screens be applied early in the season, great benefit may be derived from retarding the blossom till the frosty nights of spring be past. If the night frost has been severe, a copious sprinkling of water over the whole tree, before the influence of the morning sun be felt, has been found by Harrison to be very useful in gradually raising the temperature of the foliage and blossoms, and thus preventing injury from the sudden transition.

The Almond-Tree (*Amygdalus communis*), a native of China, may be noticed here rather on account of its affinity to the peach and apricot, than because of its importance as a fruit-tree in this country. Every good garden should contain a tree or two trained as standards; for in very fine seasons they will yield a crop, and they are always ornamental in spring from the beauty of their blossoms. The sorts most worthy of notice are:—the Tender-shelled Sweet Almond or Jordan, and the Commond Almond or Bitter.

The Almond is generally budded on seedlings of its own kind; but for heavy soils, plum stocks are preferable.

THE APRICOT.

The Apricot (*Prunus armeniaca*) is a native of the Caucasus and China; it was cultivated by the Romans, and was introduced into England from Italy in the reign of Henry VIII. It has always, and deservedly, been a favourite. The principal varieties are the following:—

Blenheim. Flowers large; fruit large; form oval; colour orange, tinged with deep yellow; flavour good; stone roundish and impervious; kernel bitter; a good bearer, and of English origin.

Breda. Flowers large; fruit roundish, sometimes almost four-cornered, orange-coloured; juice rich, stone small and impervious; kernel sweet. The true Breda is an apricot of first-rate excellence, and in the south of England the tree bears well as a standard.

Roman. Flowers large; fruit oblong, compressed, pale yellow; flesh soft; stone impervious; kernel very bitter. The tree is a good bearer, but the fruit is fit only for preserving. It is sometimes called the Brussels,—a name also occasionally given to the preceding.

Moorpark. Flowers large; fruit roundish, compressed, orange and red; flesh parting from the stone, juicy and rich; stone pervious; kernel bitter. This is generally considered the best apricot in this country. There are several sub-varieties known under different names; and among these Shipley's is the best. It scarcely differs from the *Abricot Peche* of the French.

Hemskirke. Like a small Moorpark, but with a more tender and juicy pulp, and with the rich flavour of a green-gage plum; kernel small, sweetish. A desirable early fruit, ripening on an east wall in the end of July or beginning of August.

Turkey. Flowers large; fruit middle-sized, spherical, deep yellow; flesh juicy and rich, parting from the stone, which is impervious; kernel sweet. This is an excellent late variety.

Kaisha, new early. Introduced in 1847 from Aleppo. A valuable early variety, completely superseding the Red and White Masculines, which were formerly our earliest sorts.

Musch-Musch. Fruit small; tree rather delicate, requiring a dry soil and warm situation. It is extensively cultivated in Upper Egypt, where the fruit is dried as an article of commerce.

Besides these we may mention the Large Early, the Orange and Royal. The last is a French variety; it is excellent, and ripens earlier than the Moorpark.

Apricots are propagated by budding on muscle or common plum-stocks. Mr Knight recommends the wilding apricot as a stock for the Moorpark variety. Some gardeners have adopted the horizontal form of training, but the most usual, and certainly the best, is the common fan arrangement; for the larger the tree, the greater the produce of fruit. The fruit is produced on shoots of the preceding year, and on small close spurs, formed on the two-year-old wood. The apricot is a tree of much stronger growth than the peach, and therefore requires more room; this and the peculiarity of the spurs being kept in mind, the observations made on the training and pruning of the peach may be readily applied to this tree. It requires a summer and winter pruning. The former should begin early in June, at which period all irregular fore-right and useless shoots are to be pinched off; and, shortly afterwards, those which remain are to be fastened to the wall, to become bearers. At the winter pruning, all worn-out branches, and such as are not duly furnished with spurs and fruit-buds, are removed. The young bearers are moderately pruned at the points; care, however, being taken to leave a terminal shoot or leader to each branch. The most common error in the pruning of apricots, is laying in the bearing shoots too thickly.

The blossom comes early in spring, but is more hardy than that of the peach: the same means of protection, when necessary, may be employed. The fruit often sets too numerously; and in this case it is thinned out in June and in the beginning of July, the later thinnings being used for tarts, for which purpose they are in much request. In the south of England, apricots are sometimes trained against espalier-rails, and occasionally planted as dwarf standards; and in good seasons the fruit from such trees is more highly flavoured than that from walls. In general, however, the protection of a wall is required. An east or west aspect is preferred in England, the full south being apt to induce mealiness of pulp. In Scotland the late varieties require the best aspect that can be afforded.

THE PLUM.

The Plum-Tree (*Prunus domestica*) is considered a native of England. Many of the best cultivated varieties, however, have been introduced from France. The Horticultural Society's Catalogue enumerates 274 sorts, though probably all of these are not well ascertained. We shall first notice a few of the best dessert plums, and then give a list of select kitchen sorts.

The *Green-Gage* is the *Reine Claude* of the French, a great favourite at Paris (as it is everywhere else). It is supposed to have been introduced into England by the *Gage* family, and the foreign name having been lost, it obtained its present appellation. It is a fruit of first-rate excellence, the flavour being exquisite. The tree deserves a place against an east or west wall, where the fruit acquires a larger size without materially falling off in richness of flavour. Treated as a wall-tree, it seldom bears well till it is old, and it is very impatient of exact training, as indeed most plums are. In warm situations it may be properly grown on an espalier-rail, or as a dwarf standard.

Angelina Burdett, along with *Standard of England* and *Woolston Black Gage*, originated a few years ago from seed by Mr Dowling of Woolston, near Southampton, are all plums of the highest excellence. Of them Mr Thomson says:—"These plums are first-rate, and I should recommend their extensive cultivation. As regards the last, it throws the Green-gage into the shade, for it contains all the properties of that fine plum with more sugary sweetness."

The *Drap d'Or* is a small yellow plum of high flavour, ripening in the beginning of September. On a light soil the tree is a tolerable bearer; but on a heavy soil it seldom succeeds. The fruit precedes the Green-gage in ripening, and resembles it in quality.

Coe's Golden Drop is a fine large oval plum; excellent either for the table or for preserving. It keeps well; and Mr Lindley informs us that he has eaten it exceedingly good twelve months after it had been gathered. It requires a wall of the best aspect; and will scarcely answer in a bleak climate.

For a standard, *Gisborne's Early Plum* is one of the best and most productive that can be recommended, particularly for the northern portion of Britain.

Jefferson, a comparatively new plum, of American origin. Fruit very large, golden yellow, tinged with purple on the side next the sun; tree hardy, and an abundant bearer. This is the best of all American plums, and only surpassed with us by the Green-gage, Angelina Burdett, and Woolston Black-gage.

The *Precoce de Tours* is an early sort; of a dark blue colour, with a violet bloom; pulp yellow, and of a very pleasant flavour. The tree succeeds as a standard.

The *Blue Imperatrice* is a fine late plum; the tree is a good bearer, but requires an east or west wall.

Reine Claude Violette. A very high-flavoured variety, resembling, colour excepted, the Green-gage. It succeeds on standards, but is improved by a wall. The tree is a good bearer.

Washington. Fruit large, roundish oval, pale yellow on the shaded side, and of a fine glaucous light purple on the exposed side; of excellent quality, little inferior to the Green-gage. The tree is vigorous, and bears well against a wall, the fruit ripening about the middle of August. Being an early plum, it will, in favourable situations, succeed as a standard. It is, as the name imports, of American origin. It ought to be in every collection.

Reine Claude de Bavay. The most valuable late plum of its class. Originated with M. Bavay, of Vilvorde, near Brussels.

Couper's Large Red is a plum of large size, oval; suture deeply cleft on one side; skin of a bluish glaucous purple on the exposed side; on the other dull red; flesh firm, adhering to the stone; ripening in Scotland in the beginning of September on a south wall. Although this is only a plum of the second quality, yet the tree well merits a place, on account of its great productiveness.

The following are also first-rate plums:—D'Agen, Coe's Late Red, Downton Imperatrice, Kirke's, Blue Perdrigon, White Perdrigon, and Lawson's Golden-gage.

The Cheston, Fotheringham, Goliath, Orleans, Wilmot's New Orleans, La Royale, Sharpe's Emperor, Morocco, and some of the Damasks, though generally regarded as only second-rate plums, deserve notice, and should always have a place in large gardens. The Early Violet is an excellent bearer, and strongly recommended by Lindley to be planted in cottage gardens. Lucomb's Nonsuch plum should not be omitted; for when well ripened, it makes an approach to the Green-gage in flavour.

As kitchen and preserving plums, we may specify the Shropshire Damson, Imperial Diadem, Isabella, White Magnum Bonum, Red Magnum Bonum or Imperiale; the Caledonia or Nectarine Plum, a large and handsome fruit; the Mirabelle, St Catherine, Wine Sour, and Bullace. Dean's Jedburgh Seedling, Denniston's Superb, Gisborn's, Guthrie's new Apricot Plum, Tay-bank Plum, Topaz, Guthrie's Minette, and Pond's Seedling.

Plums are propagated chiefly by budding on Muscle or St Julian stocks. They are sometimes grafted, but gum is apt to break out at the place of junction. The damson, wine sour, and other varieties, planted as standards, are generally increased by suckers, which the old plants afford plentifully. For placing against walls, trees which have been trained for two years in the nursery are to be preferred.

Plum-trees require ample space. On common walls they should be allowed from twenty to twenty-five feet of breadth over which to extend themselves. The horizontal mode of training is adopted by many. The fan form is also very commonly followed, and undoubtedly, where there is room, it is the best. The shoots ought to be laid in at full length. The fruit is produced on small spurs, on branches at least two years old. The same spurs continue fruitful for several years.

Standard plum-trees require only to have a portion of their wood thinned out occasionally when they are young. The hardy kinds grown in this way are very productive, and in some places in the north of England, their produce forms a considerable article of food for several weeks, and also an article of commerce, particularly the wine sour and damson, which is in great request for preserves. It is matter of regret that this branch of fruit culture has not, as yet, met with due attention in Scotland.

The **Cherry-Tree** (*Prunus Cerasus*), is said to have been introduced into Europe from Pontus, by the celebrated Lucullus, B.C. 73. From the "London cries" of Lydgate, it appears that "cherries in the ryse," or in twigs, were hawked in London at the beginning of the 15th century. Excellent sorts have at various times been introduced from the Continent, and, of late years, several first-rate new varieties have been raised in England. Geans included, the Horticultural Society's Catalogue enumerates no fewer than 219 varieties; the following may be accounted some of the best:—

The *Early Purple Griotte* may be first mentioned as being the earliest of all cherries, generally ripening in the end of May.

The *May-Duke* is one of the most common, and, at the same time, one of the most valuable cherries. In fine seasons, and on a good aspect of wall, it begins to colour in May; and in such situations it is generally ripe from the middle to the end of June. The tree also bears well as a dwarf standard, but against a wall the fruit gets larger, and does not fall off in flavour.

The *Late Duke* is a rich sweet cherry, with most of the qualities of the May-Duke. It is identical with the Arch-Duke.

Bigarreau or *Graffion.* This is an excellent fruit, especially when it gets the protection of a wall. In the cherry orchards of England, this sort is now pretty extensively cultivated, the fruit meeting with a ready sale, and vast quantities being required for the London market.

Harrison's Heart is nearly allied to the Bigarreau; it is rather of larger size and of finer appearance in the dessert, but inferior in flavour. The fruit has this advantage, that it is not liable to crack in wet weather.

Belle de Choisy, an excellent cherry. The fruit come in pairs, red, mottled with amber colour, tender and sweet. The tree bears well as a standard.

Black Tartarian. Fruit large, obtuse heart-shaped; flesh half tender. "The quality is good, and in appearance it is one of the finest." It is a good bearer, and well adapted for forcing.

Waterloo. Raised by a daughter of Mr Knight, from the Bigarreau and May-Duke. Fruit black, large, obtuse heart-shaped, pulp tender. It ripens in July, and the tree is a free bearer.

Elton. Raised by Mr Knight from the Bigarreau and White Heart. Fruit large, heart-shaped, pale red, with a sweet delicious juice. The tree is a good bearer and hardy; the fruit ripens shortly after the May-Duke.

Kentish Cherry. One of the oldest and most prevalent cherries in England, abounding in the orchards of Kent. When ripe, it is of a full red colour, and its subacid flavour is very agreeable. It is commonly grown on standards, and ripens in the end of July. The *Hort. Cat.* distinguishes this from the *Flemish* or short-stalked, also a good cherry, to which it is certainly closely allied.

The *Morello.* This is a well-known late cherry, much in request for confectionery. The tree is a copious bearer as a standard, and on a south wall the fruit acquires a peculiarly rich subacid flavour. It succeeds perfectly well on a north aspect, where its fruit may be retarded to the end of October.

The *Amber*, or Yellow Spanish, is a late fruit, and useful in prolonging the cherry season till the beginning of September. It requires a west wall.

Among other excellent varieties may be mentioned the Black Eagle, Black Heart, Bowyer's Early Heart, Carnation, Downton, Florence, Knight's Early Black, and the White Heart.

Buttner's October Morello. An excellent German variety of this useful section of cherries, remarkable for its hanging on the tree till the end of November. The Late-Duke, White Tartarian, and Buttner's Black Heart are also valuable. To that useful section (the Morello), we may add a new acquisition, the Frogmore new Morello, and Rumsey's late Morello.

What are called *geans* or *guignes*, are cherries less removed from their natural state. They are usually

Fruit Garden.

grown as standards, and bear abundantly, particularly when old. The principal sorts are the Amber gean, a plentiful bearer, with sweet tender fruit; and the Lundie gean, a small black cherry of high flavour.

In the Jardin des Plantes at Paris, the black-fruited cherry-tree, or *Guignier*, is considered as a variety of *Prunus Cerasus.* The forest cherry-tree, *P. avium*, is named *Merisier*; and, besides varieties with red and with black fruit, there is a marked variety called *Bigarotier.*

The great quantities of pale-coloured cherries yearly sold in the London market are chiefly of the kinds called White Heart and Bigarreau. The dark-coloured cherries are chiefly the Courone, which is often passed upon buyers for the Black Heart.

The stock preferred for cherries is the wild gean. Mr George Lindley recommends that dwarf cherry-trees should be grafted, and two or three year-old stocks will do for them.

For standard trees the stocks should be at least four years old, and they should be budded or grafted five or six feet from the ground. High-stemmed cherry-trees, or *riders*, are often temporarily employed to fill up the vacant spaces on newly planted garden walls, till the dwarf trees make sufficient progress; for these, stocks six or seven feet high are required. For dwarf cherry-trees, the best stocks are procured from the *Prunus* (or *Cerasus*) *Mahaleb*, the sweet-scented cherry.

Cherries are generally produced on small spurs which appear on the wood of the second year, and these spurs continue productive for an indefinite period. Any form of training may therefore be adopted; but as the fruit is always finest on young spurs, perhaps fan-training, which admits of the frequent renovation of the bearing branches, is the most advantageous. A succession of young shoots should be laid in every year. For the Morello, which is of twiggy growth, and bears on the young wood, the fan form is absolutely necessary. Whatever method be adopted for general practice, care should be taken not to crowd the branches; for nothing is more unfavourable to the productiveness of the trees than overcrowding of branches.

The *Prunus Marasca*, from the fruit of which is prepared the celebrated liqueur called Maraschina di Zara, is a native of Dalmatia, and would doubtless succeed in Britain, if fairly tried.

THE PEAR.

The Pear-Tree (*Pyrus communis*) is considered by botanists as a native of England. Many cultivated varieties seem to have been introduced by the monks. Remains of perry orchards attached to monasteries of the fourteenth and fifteenth centuries are not uncommon, even in Scotland, and very ancient trees of the finer dessert pears, such as the Colmar and Longueville, are occasionally found.

The list of cultivated pears amounts to more than 600 names; but the number of those truly desirable is not large. We shall specify some of the best dessert fruit, following the usual division of Early and Late; the former class being in season in the months of August, September, and October, and the latter in November, December, and January. It is only a few years since pears fit for the dessert in January were known in Britain; such as the Glout morceau, the Easter Beurré and the Winter Beurré; and they deserve the best attention of horticulturists. It is to be premised, however, that even within the limits of Britain, climate makes an important difference in the culture and ripening of pears, of which a remarkable and extreme example may be seen in the Chaumontelle—a fruit which is produced abundantly and ripened on standards in the south-west of England, and even in the environs of London, while it requires a south wall near Edinburgh.

1. *Early.*

Citron des Carmes (*Madeleine* of Lindley, and in Scotland often called the Premature). This is the earliest pear; it ripens in July, acquiring a yellowish-green colour; it is sweet, but without much flavour. One tree may suffice. It requires a sheltered situation.

Beurré d'Amalis. Above medium size; colour greenish-brown; form obovate; quality excellent; ripe in September.

Doyenné blanc. Colour pale yellowish; about medium size; pyriform; quality excellent; ripe in September and October.

Dunmore. Brownish-green russet; size large; obovate; quality first-rate. Tree hardy and an excellent bearer; ripe in September.

Flemish Beauty. Colour russet-red; obovate; size large; quality excellent; tree hardy; ripe in September.

Fondante d'Automne. Colour pale green; obovate; under medium size; quality excellent; ripe in September and October.

Mansuette. Pale green and brown; size large; oblong obovate; quality excellent; ripe in September and October.

The *Summer Rose.* A handsome round pear, of a russety-red colour, much resembling an apple, flesh white, rich and sugary. This is an excellent variety, succeeds on a standard, and ripens in August.

The *Jargonelle* of Britain is the *Grosse Cuisse Madame* of the French. This is the most common and most esteemed of our early autumn pears. Against the wall the fruit attains a large size and a beautiful appearance; but it is not of so high a flavour as from standards or espalier-rails. The fruit does not keep well, and the tree should therefore be planted in various situations to prolong its season, as it is rather difficult, when it disappears, immediately to supply its place in the dessert.

The *Summer Francréal*, or the Yat of Holland, may be noticed as another pear to follow the Jargonelle, as it ripens about the middle of September. The tree proves, in general, a great bearer.

The *Duhamel* is a good autumn pear, with a delicate flavour. From a wall, it comes in immediately after the Green Yair, and helps to fill up a gap in the pear season, especially in Scotland; standards produce freely, and their fruit is ready in November.

The *Seckle*, of American origin, is of dwarfish size, suited for a border standard, and it seldom fails to yield a crop. The fruit is small, but melting and perfumed. It does not keep.

The *Red Doyenné*, or as it is sometimes called Gray Doyenné, is also an excellent autumn pear, succeeding best on a quince stock.

The *Elton.* Capital as a standard, in ordinary situations. The tree produces healthy wood, and the fruit ripens in September and October.

The *Early Bergamot* was introduced from France in 1820. It is one of the very best early pears, as the tree bears freely as an open standard.

The *Autumn Bergamot*, or English Bergamot, has been long known as one of the most highly flavoured pears. It is not the *Bergamotte d'Automne* of the French, which is liable to canker in this country, while the English bergamot is not. In England the tree succeeds perfectly well as a standard; and in Scotland it answers in good seasons, where it is deserving of a west wall. The fruit is of a depressed globular shape, not large; the flesh juicy, sugary, and rich, a little gritty next the core. It ripens towards the end of October, but does not keep.

The *Van Mons Leon Leclerc* is one of the best autumn pears, ripening from the middle to the end of October. It is of the size and shape of the *Duchesse d'Angouleme;* sugary, and with rich pine-apple flavour.

To the list of summer and early autumn pears might be added the Musk Robine, Summer Francréal, Summer Bonchretien, and William's Bonchretien, generally requiring the protection of a wall; and Ambrosia, Caillot Rosat, and the Hazel Pear.

2. *Late.*

The *Brown Beurré* (Red, Gray, Royal Beurré of various authors). This is a first-rate melting pear. Against a wall with a good aspect, and with a fresh soil, the tree is an abundant bearer. Ripens in October and November.

Belle et Bonne. Yellowish green; size large; roundish; quality good; ripe in September and October.

The *Beurré de Capiaumont.* This is one of the best Flemish varieties. The fruit is beautiful and well flavoured. It ripens in October and November. The tree is a great bearer and hardy.

The *Moorfowl Egg.* There are two varieties, both of Scottish origin, of which the Galston Moorfowl Egg is the best. The fruit is not attractive in appearance, but it is of admirable quality. The tree is hardy, and should be grown as a standard.

Fruit Garden.

The *Gansel's Bergamot* (sometimes called Brocas Bergamot). This noble pear, which has scarcely been rivalled, certainly not surpassed, by any of the imported varieties, is of English origin. Its blossoms are too tender to enable the tree to succeed as a standard; but it deserves a wall, and it should be placed on various aspects to prolong its season. The fruit ripens in November and December.

Gansel's late Bergamot, having many of the properties of the original, but is harder and sets better.

Bergamotte de Hollande. Esteemed for its long keeping. In use from March till June.

Beurré Bosc. Russet coloured; size large; pyramidal; quality excellent. In use in October and November.

Beurré Gris d' Hiver. Size large; quality first-rate; very productive; one of the best pears in cultivation. In use during February.

Beurré Diel. Yellowish brown; obovate; size large; quality excellent. In use in October and November. One of the most profitable of the Flemish pears.

Beurré Langelier. Size large; obovate; quality first-rate. In use in October and November. One of the very best autumn pears, and exceedingly hardy.

Bezi de La Motte. Pale yellowish green, with russety dots; size medium; roundish; quality good. In use in October. Deserves a place in every garden.

The *Marie Louise.* This excellent and large pear was raised by the Abbé Duquesne. "It is," says Mr Thompson, "one of the very finest, even as a standard, on which it bears abundantly; it succeeds also well on a north wall." In Scotland it is the better for an east or west aspect; but on a standard in a sheltered garden at Luffness, East Lothian, the fruit has attained the weight of 15 ounces. It ripens in October and November.

Beurré d'Aremberg. Is perfectly melting and without grittiness, and rich, sweet, and high-flavoured. The tree succeeds either trained against an east or a west wall, or as a standard in any sheltered situation.

Crasanne. An old French sort, of excellent quality, with a tender and finely flavoured pulp. The tree deserves an east or west aspect on the wall, and it succeeds also on an espalier-rail. The fruit ripens in November and December.

The *Urbaniste* is a very good variety, of a large size, and ovo-globular shape; skin of yellowish colour, with small russety spots; flesh white, melting, with a sweet well-flavoured juice. In Scotland ripens against a south wall by the beginning of November.

Colmar. This is a first-rate pear, with a white flesh, and of high flavour. In Scotland the tree requires a south wall. This is the Poire d'Auch of the Continent. It keeps till February or March.

Passe Colmar. An admirable Flemish variety; of excellent flavour; hardier, and a more abundant bearer than the preceding, and more easily ripened. It is in maturity in December and January.

Poire Neill was raised by M. Van Mons of Louvain. It is a large handsome fruit, with a very white pulp, mellow, and abounding with a saccharine and slightly musky juice. It is in season during the month of October, and should be gathered a few days before it is ripe. The tree succeeds as a standard at Edinburgh, and bears freely.

The *Easter Beurré.* Fruit large, obovate, green and brown; flesh whitish-yellow, buttery, and extremely high-flavoured. "It is," says Mr Thompson, "hardy and a good bearer; one of the most valuable spring sorts, compared with which the early pears of short duration deserve not a wall; its extensive cultivation for a long and late supply is, without hesitation, strongly recommended." In season from January to March. As the tree ripens its wood readily, it succeeds as a standard, even in Scotland, and yields fruit superior in flavour to that from the walls.

Beurré Rance. A Flemish variety, raised by the late M. Hardenpont; "the best very late sort yet known," *Hort. Cat.* It ripens with difficulty in Scotland.

The following, also, may be considered highly valuable sorts as late autumnal and winter pears:—Autumn Colmar, Astontown, Echassery, Delices d'Hardenpont, Beurrê Spence, Bezi Vaet, Bezi de la Motte, Chaumontelle, Sylvange, Downtown, Glout Morceau, St Germain, Duchesse d' Angoulême, Hacon's Incomparable, Winter Nelis, Swan Egg, Doyenné gris, Flemish Beauty, Napoleon, Beurré d'Aremberg, Bonchretien Fondant, Brougham, Calebasse, Chaptal, Comte de Lamy, Althorp Crasanne, Winter Crassane, De Louvain, Dundas, Elton, Emerald, Eyewood, Fondante du Bois, Forelle, Fulton, Groom's Princess Royal, Jean de Witte, Louise Bonne of Jersey, Moccas, Knight's Monarch, Ne Plus Meuris, Thompson's.

Of the *Kitchen Sorts*, or stewing pears, we may name the Bellisime d'Hiver, Catillac, Uvedale's St. Germain, Warden or Black Worcester, and the Gilogil. These are placed on inferior walls, or upon espalier-rails, or kept as dwarf standards. The Uvedale's St. Germain fruit often attains a large size, especially against a wall.

Pear-trees are grafted either on what are called free-stocks or on dwarfing stocks: for the former, which are intended for full-sized trees, the seeds of the wilding pear should be sown; but frequently the pips of the perry pears, and sometimes of the common cultivated sorts, are used. For dwarfing, the quince is preferred; but the white-thorn, as already mentioned, is occasionally employed. Where the space is limited, or the ground is damp, the dwarfing stocks are the more suitable. It is a favourite doctrine with some, that by budding or grafting on quince or hawthorn, pears of too melting and sugary a quality acquire firmness and acidity; to what extent this holds good has not been correctly ascertained, but that the stock exerts a certain degree of influence on the fruit is beyond dispute. Some of the finer pears do not take readily on the quince. In this case double working is resorted to. For example, the Virgouleuse may be easily budded on the quince, and the Beurré d'Aremberg will afterwards succeed freely on the Virgouleuse. It may be mentioned in passing, that the ancient horticulturists seem to have supposed that a fruit was improved by double working; and that the term *reinette*, a name applied to a class of apples, is considered as having been derived from the Latin *renata*, that is, a tree grafted upon itself.

In selecting young pear-trees, some prefer *maiden plants*, that is, plants one year grafted; but if good trees, trained for two or three years, can be procured, so much the better. It is important to ascertain that the stock and stem be clean and healthy, and to take great care that no injury be done by bruising or tearing the roots, in lifting and removing. The trees should be planted immediately after the fall of the leaf. Wall-trees require from 25 to 30 feet of lineal space when on free stocks, and from 15 to 20 feet when dwarfed. Standards on free stocks in the orchard should be allowed at least 30 feet every way, while for dwarfs 15 feet may suffice. Where the trees are trained *en pyramide* or *en quenouille* (see figs. 2, 3), they may stand within eight feet of each other. It is very desirable that the pear orchard should be in a warm situation, with a soil deep, substantial, and well drained, or free from injurious latent moisture. Without attention to these circumstances, pear-trees seldom succeed. Mr Rivers, one of our most successful pear cultivators, recommends planting pear trees on quince stocks, so that the stock may be covered up to its junction with the graft. This is effected by raising up a small mound of rich compost around it, a contrivance which induces the graft to emit roots into the surface soil, and also keeps the stock from becoming hard or bark-bound.

The fruit is produced on spurs, which appear on shoots more than one year old; the object of the pruner therefore ought to be to procure a fair supply of these spurs. The mode most commonly adopted of training wall pear-trees is the horizontal; but each of the forms already mentioned has its advantages, and is peculiarly adapted to some particular habit of growth in the several varieties. For the St Germain, and other twiggy sorts, the fan form is to be preferred; for the Gansel's Bergamot, and other strong growers, the half-fan or the horizontal. In the latter form the trees may often be found fifteen, twenty, or even thirty years old, during which time they acquire an undue projection from the wall, and become scraggy and unmanageable. On the other hand, the finest fruit is produced on young spurs, clearly indicating the necessity of a frequent renovation of the spurs. This would lead to a preference of the fan form, not, indeed, that which is commonly practised, for in it the spurs are as immovable as in any other

Fruit Garden.

Fruit Garden.

arrangement; but rather that recommended for peaches, in which there is a continual renewal of the branches. Or, if the horizontal form, which has certain advantages, be adopted, it should be that modification exhibited in fig. 5, *a*. This is the method followed by Harrison in treating the Jargonelle. Or a portion of the old spurs should be cut out annually, which will induce young ones to form.

The summer pruning of established wall or espalier-rail trees, consists chiefly in the timely displacing or rubbing off the superfluous shoots, retaining only those which are terminal or well placed for lateral branches. In horizontal training, the winter pruning is nothing more than adjusting the leading shoots, and thinning out the spurs, which should be kept close to the wall, and allowed to retain only two, or at most three buds. In fan-training, the subordinate branches must be regulated, the spurs thinned out, and the young laterals, which had been loosely nailed in during summer, must be finally established in their places. No crowding of branches should be permitted. When horizontal trees have fallen into disorder, they may be renovated in the manner represented at fig. 5, *b*, a method approved by Knight; or all the branches may be cut back to within nine inches of the vertical stem and branch, and trained in afresh, as recommended by Mr Lindley. Or they may be grafted with other sorts if a variety is wanted.

When some of the finer pear-trees produce an abundance of blossom, but do not *set* well, as not unfrequently happens, artificial impregnation may be partially resorted to; that is, the blossom of some other kind of pear, plentifully provided with pollen, may be taken, and the farina dusted over the best-looking blossoms of the less productive tree.

Summer and autumn pears should be gathered before they are fully ripe, otherwise they will not in general keep more than a few days. The Jargonelle, as Forsyth rightly advises, should be allowed to remain on the tree, and pulled daily as wanted, the standard fruit thus succeeding the produce of the wall-trees. In reference to the Crasanne, Mr Geo. Lindley recommends gathering the crop at three different times, the first a fortnight or more before it is ripe, the second a week or ten days after, and the third when fully ripe. The first gathering will come into eating latest, and thus the season of the fruit may be considerably prolonged. It is evident that the same method may be followed with the Brown Beurré and Gansel's Bergamot, or with any others which continue only a short time in a mature state.

THE APPLE.

The Apple-tree (*Pyrus Malus*) is, under the name of the Crab, known as a native of Britain. Most of the cultivated sorts, however, are of foreign origin. The finer, high-flavoured apples are prized for the dessert; the juicy and poignant sorts are in request for tarts and sauce; while those of a more austere nature are manufactured into cider, and on the continent very largely into brandy. In the second edition of the London Hort. Society's Catalogue, no fewer than 1400 varieties are enumerated; many of them doubtless not well ascertained, but about 175 are pronounced to be excellent sorts. And a few have been since added in the supplement to the 3d edition, the best of which will be noticed. With such a multitude before us, it would be vain to attempt detailed descriptions; we shall therefore do little more than give a list of those most worthy of attention.

Table Apples.

The earliest of these are the following:—The Juneating, or White Geniton, which begins to ripen in the end of July, and being sugary and slightly perfumed, forms a welcome addition to the dessert. The Early Margaret, or as it is sometimes called Red Juneating or Striped Juneating, and in Ireland Peach Apple. The Summer, or White Crofton, is of Irish origin: the tree bears abundantly; and if the fruit be scarcely equal to the Juneatings for the dessert, it is very desirable for culinary purposes in August. The Oslin or Arbroath Pippin, and the Early Julien of Clydesdale, also deserve notice. The Summer Golden Pippin, the Red Quarrenden of Devonshire, and the Early Harvest, are likewise excellent early dessert apples.

To succeed these in the autumn we have many fine sorts, such as the Early Nonpareil or Hicks's Fancy; the Doonside; Autumn Pearmain or Royal Pearmain of the London Nurseries; Shepherd's Fame; Baird's Favourite; White Astrachan; Red Astrachan: Maclean's Favourite; Pearson's Plate; Pomme de Niege, and Bourassa; Franklin's Golden Pippin, fruit not equal to the Old Golden Pippin, but the tree more productive; Old Golden Pippin; King of the Pippins or Hampshire Yellow, a valuable sort; Kerry Pippin, one of the finest Irish apples; and the Cole Apple or Scarlet perfumed; Leisham's Pippin, a large fruit; Longville's Kernel, of good quality.

The winter dessert apples are very numerous, so that only a few can be mentioned. The Ribston Pippin has long maintained a pre-eminent character, for its rich juiciness and highly aromatic flavour. Hubbard's Pearmain is a Norfolk apple of the very finest quality, and too little known, especially in Scotland. The Dutch Mignonne is another admirable dessert apple, too little known or attended to. The Golden Harvy, or Brandy Apple of Forsyth, is a beautiful though small fruit, and Mr Lindley characterizes it as rich, juicy, spicy, and high-flavoured: the tree is not a large grower, is very hardy, and a great and constant bearer; and no garden, adds Mr Lindley, "capable of containing ten trees, ought to be without one of it." The Downton Pippin, raised by Mr Knight from the Orange Pippin of Herefordshire, dusted with the pollen of the Old Golden Pippin, must not be omitted. The tree is a great bearer; the fruit ripens in the end of October and keeps till January. The Yellow Ingestrie, raised by the same gentleman, is likewise excellent. To these may be added the Beachamwell; Borsdoffer; Court of Wick Pippin, excellent, though of small size; Wood's Transparent; Margill; Scarlet Crofton; Golden Pearmain; Scarlet Pearmain; Dutch Mignonne; Fearn's Pippin; Gravenstein; Paradise Pippin; Old Nonpareil; Ross Nonpareil; Braddick's Nonpareil, very fertile; Scarlet Nonpareil; Pitmaston Nonpareil; Sturmer Pippin; Kirke's Golden Rennet; Reinette de Canada; Sykehouse Russet; Cornish Aromatic, of first-rate quality; and the Sam Young, an excellent Irish apple brought into notice by Mr Robertson of Kilkenny. The Courtpendu plant is a capital winter dessert fruit: the tree is hardy and productive, and the blossom being late in expanding, it is a kind well adapted for cold situations. The Norfolk Beaufin is the best apple for drying and preserving, making an excellent winter preserve.

Dessert Apples.

Ashmead's Kernel; Baddow Pippin; Barton's Incomparable; Breedon Pippin; Christie's Pippin; Clara Pippin; Cockle Pippin; Colonel Vaughan's White Crofton; Cornish Gillyflower; Creed's Marigold; Elford Pippin; Forman's Crewe; Scarlet Golden Pippin; New Golden Pippin; Golden Russet; Winter Golden Pearmain; Lucombe's Pine Apple; Morris's Court of Wick; Morris's Russet; Newtown Pippin; Pitmaston Nonpareil; Ord's Apple; Adam's Pearmain; Claygate Pearmain; Herefordshire Pearmain; Mannington's Pearmain; Lamb Abbey Pearmain; Scarlet Pearmain; Hubbard's Pearmain; Royal Pearmain; Ravelston Pippin; Reinette Franche; Reinette Grise; Powell's Russet; Keeping Russet.

Of American Apples, the best for our climate is the Boston Russet. Mr Thompson states that the tree is quite hardy, very productive, and suitable for dwarf training; the fruit juicy, with a flavour between that of the Ribston and Nonpareil, and in season from December till April. The Newton, or Long Island Pippin, seldom comes to perfection in this country.

Kitchen Apples,

Or such as are chiefly used for tarts or for sauce, are very numerous, and the names of a few of the best can only be given. The Red Fulwood, the Nonsuch, Minshul Crab, Hanwell Souring, Cat's Head, Alexander, Wheeler's Russet, Blenheim Orange, Hunthouse of Yorkshire, and Forman's Crewe, all are good. The Bedfordshire Foundling is a large and handsome apple and the tree a sure bearer. The Cellini is a good kitchen apple for November, the tree hardy and very productive, and the fruit beautiful. Among the best long-keeping apples are the Scottish Gogar Pippin, sometimes called Moncreiff Pippin, or Stone Pippin; Wormsley Pippin; and the Yorkshire Greening and Northern Greening, particularly the latter; Baxter's Pearmain; Winter Strawberry Apple; the Tulip, a small Dutch fruit, of a dark red colour, and with a lively juice; Calvill Malingre; Dutch Mignonne; Winter Lud; Pentcaitland Pippin; Cambusnethan Pippin. The Cockle Pippin or Nutmeg Apple, an excellent apple, and the tree a fertile bearer. Dumelow's Seedling is a very juicy kitchen apple, and keeps firm till April, and the tree is not liable to canker. The Green Fulwood is a good kitchen apple, and keeps till May. The same may be said of the Hoary Morning, and the tree is a great bearer. The Cockpit is a useful culinary apple for winter; the tree hardy and a great bearer. The New Cockpit is an excellent apple, remarkably perfumed. An apple, called the French Crab (but which is of a considerable size, notwithstanding this name), keeps firm in substance till the return of the apple season; and the subvariety of this, called Hambledon's or Deux-ans, is described in Ronald's "Pomona" as still superior. Alfriston; Beauty of Kent; Belle Bonne; Bess Pool; Brabant Bellefleur; Calville Blanche d'Eté; Calville Blanche d'Hiver; Chalmer's Allan Bank Seedling; Cobham; Keswick Codlin; Manx Codlin; Carlisle Codlin; Dumelow's Seedling; Easter Pippin; Ecclenville Seedling; Flower of Kent; Gloria Mundi; Glory of England; Hawthornden; Hoary Morning; London Pippin; Melrose; Pope's Apple; Royal Russet.

Several kinds of stocks are used for apple-trees. The Dutch *paradise*, propagated by layers, has long been used as a stock for dwarf apple-trees, whether intended for the wall or for standards. The *doucin* of the French seems closely allied to this, if not identical with it. The bur-knot varieties increased by cuttings, or young codlin plants procured from layers, furnish convenient stocks for trees of a very diminutive habit. For common purposes, the stocks raised from the pips of crabs or of cider apples are preferred. Stocks kept one or two years in nursery-lines are fit for grafting upon; but if a considerably tall stem be wished, they must remain three or four years in the nursery, and be pruned up, till they attain five or six feet of height. Any common soil, provided the subsoil be dry, suits the apple-tree. Shallow planting should, in all cases, be practised, and young trees should be carefully staked, to prevent wind-waving.

The fruit, as in the pear-tree, is produced on spurs, which come out on the branchlets of two or more years' growth, and continue fertile for a series of years. There is, therefore, no very material difference in the pruning and training of the pear and of the apple tree. On walls, the horizontal mode of training is commonly followed, as best calculated to repress the too vigorous growth of the tree; but for the Nonpareil, and other twiggy varieties, perhaps the fan form, or some modification of the fan form, is preferable. For standards, where the soil is rich and the growth rapid, all that is necessary in pruning is to thin out the branches, and to prevent their crossing and rubbing against each other. Where there is little luxuriance, as in the case of all dwarfs, it is useful to shorten the branches occasionally, and to remove useless twigs. Dwarfs on paradise stocks may be treated almost like currant-bushes; that is, making them open in the centre, or cup-shaped, to the great advantage both of the size and beauty of the fruit. The general winter pruning may take place any time from the beginning of November to the beginning of March. After the winter pruning, some cultivators delay the shortening of the young wood of the former year till the middle or end of April, when the buds have swollen. Cankered or diseased wood, and all unfruitful snags or ragged spurs, are then to be neatly cut out. Where the scars are large, they should be laid over with some composition calculated to resist the action of the air and rain.

If the American blight, or woolly aphis (the *Eriosoma Mali* of Leach) make its appearance on a tree, the utmost care should be taken to clean every part of the bark with a hard brush and some searching wash; for, should the insect be left unmolested, it will speedily spread over all the apple-trees in the neighbourhood. Mr Waterton, in his Essays on Natural History, recommends a simple remedy, which he found effectual, viz., mix clay with water till it be of a consistency to be applied like thick paint to the injured parts, either with a trowel or a brush; a second coat upon the first fills up every crack which may shew itself when the first coat becomes dry; the clay resists for a sufficient length of time the effects both of sun and rain, and before it gradually falls off, every insect is completely smothered. Painting the trees during winter with vegetable spirits of tar is also an effectual remedy.

For the *Storing of Pears and Apples*, there should be attached to every considerable garden a commodious fruit-room, well ventilated, and fitted up with a variety of shelves, drawers, &c. A northern aspect is the most suitable; and it is also desirable that there should be a dry, cool cellar under it, to be employed in retarding the maturation and decay of some of the more fugitive varieties. All the fruit intended for keeping should be plucked with the hand, and when it is perfectly dry. For the finer dessert fruits the shelves should be made of hard wood, not of fir, and the fruit should be laid upon cartridge or writing paper, to prevent its imbibing any taint from the wood. The kitchen fruit may be kept in layers two or three deep, but not in heaps, and should be occasionally examined when decaying fruit is to be removed. The *sweating* of apples and pears, formerly much practised, is now abandoned, as being attended with no useful effects. Darkness, and a low uniform temperature are essential conditions. To ensure the latter, the walls should be built hollow, and lined internally with boarding kept an inch or two from the walls. The roof must also be rendered impervious to sun, heat, and frost.

THE QUINCE.

The Quince (*Cydonia vulgaris*), allied to the apple, is a native of the south of Germany. It is but little cultivated in Britain. The fruit, which is austere when raw, is well calculated for giving flavour and poignancy to stewed or baked apples. The two principal sorts are the Portugal Quince and the Pear Quince, of which the latter is the most productive, while it serves the usual culinary purposes equally well as the other. Quinces may be propagated by layers, or by cuttings, or by grafting. Two or three trees planted in the slip or orchard are in general sufficient. In Scotland, the fruit seldom approaches maturity, unless favoured by a wall.

THE MEDLAR.

The Medlar (*Mespilus germanica*) is a native of the south of Europe, but has been naturalized in some parts of the south of England. The varieties worth notice are the Dutch Medlar, with broad leaves; and the Nottingham Medlar, with narrow leaves; of these the latter is considered the best. The fruit is gathered in November, and kept till it begins to decay, when it is served up in the dessert, and highly relished by some. The treatment recommended for the Quince may be applied to the Medlar.

THE SERVICE-TREE.

The Service-Tree (*Pyrus domestica*) is a native of the mountainous parts of Cornwall, and though not much cultivated, may be here noticed. The fruit has a peculiar acid flavour, and is used only when thoroughly mellowed by keeping. There is a pear-shaped, and also an apple-shaped variety, both of which may be propagated by layers, and still better by grafting on seedling plants of their own kind. Two or three trees may have a place in the orchard, or perhaps in a sheltered corner of the lawn. The tree is seldom productive till it has arrived at a goodly age. The fruit is brought to Covent Garden

Market in winter; but it is never seen at Edinburgh. Near Paris, the tree is a good deal cultivated under the name of *cornier*; and there are several varieties of the Service grown in the north of Italy.

THE MULBERRY.

The Mulberry (*Morus nigra*) is a native of Persia, and in this country requires a warm sheltered situation. The fruit is in request for the dessert during the months of August and September, having a rich aromatic flavour, and a fine subacid juice. Where it is abundant, wine is made from it. In Devonshire, a little of the juice added to full-bodied cider, produces a delicious beverage, called Mulberry Cider, which retains its flavour for many months. The Mulberry is propagated by cuttings or by layers, and also by branches of an inch or more in diameter. Mulberry standard trees succeed only in the southern counties. These require no other training than an occasional thinning out of the branches. They are generally planted on grassy lawns, so that when ripe fruit falls from the higher branches, it can be gathered up without having sustained injury. In the middle districts, espalier-rails may be employed. In colder situations, the mulberry must be treated as a wall-tree; and it has been recommended that the bearing shoots should be trained perpendicularly downwards. The Mulberry as a fruit is little known in Scotland; but a few aged trees exist in old gardens, and in favourable seasons afford berries.

THE HAZEL-NUT.

The Hazel (*Corylus Avellana*), one of our indigenous edible nuts, is the original parent of the red and white Filbert, Cobnut, Cosford-nut, Frizzled, Spanish, and other improved varieties. These succeed best on a rich dry loam, carefully worked, and receiving from time to time a slight manuring. They are generally planted in the slip, but thrive best in an open quarter by themselves. The varieties are propagated by layers or by suckers; but where there are stocks of the common hazel, the other kinds may be grafted upon them. The Cosford is generally preferred, being thin-shelled, and having a kernel of high flavour. If the Filbert or the Cosford be grafted on small stocks of the Spanish nut, which grows fast, and does not send out side suckers, dwarfish prolific trees may be obtained; and by pruning the roots in autumn, the trees may be kept dwarf.

The neighbourhood of Maidstone in Kent has long been celebrated for the culture of nuts for the London market; and as the best Kentish practice is scarcely known in other parts of Britain, we may enter a little into detail. The young plants are almost always suckers from old bushes, and are planted about ten or twelve feet apart. They are suffered to grow without restraint for about three years, and are then cut down to within a few inches of the ground. They push out five or six shoots; and these in their second year are shortened one-third. A hoop is then placed within the branches, and the shoots are fastened to it at nearly equal distances. In the spring of the fourth year, all the laterals are cut off close by the principal stems, and from these cut places short shoots proceed, on which fruit is expected in the following year. Those which have borne fruit are removed by the knife, and an annual supply of young shoots is thus obtained. The leading shoots are always shortened about two-thirds, and every bearing twig is deprived of its top. In the early spring-pruning, attention should be given that a supply of male blossoms be left, and all suckers should be carefully eradicated. These Kentish nut-plantations somewhat resemble large quarters of gooseberry-bushes, few of the trees exceeding six feet in height.

THE WALNUT.

The Walnut (*Juglans regia*) is a native of Persia, and the south of Caucasus; in Britain, therefore, the fruit seldom comes to complete maturity, except in the warmer districts. Besides the common walnut, there are several varieties cultivated, particularly the Large-fruited or Double Walnut, the Tender-shelled, and the Thetford or Highflyer, which last is by far the best walnut grown. The varieties can be propagated with certainty only by budding; but the operation is rather nice, and not unfrequently fails. Plants raised from the seed seldom become productive till they are twenty years old. The fruit is produced at the extremities of the shoots of the preceding year; and therefore in gathering the crop, care should be taken not to injure the young wood. In Kent, the trees are thrashed with rods or poles; but this is rough; and far from being a commendable mode of collecting the nuts.

THE CHESTNUT.

The Chestnut (*Castanea vesca,*) like the preceding, has long been an inmate of our woods, in which it grows to a great size; but it seldom ripens its fruit in the northern parts of the island. Several varieties, remarkable for their productiveness and early bearing, have risen into notice, particularly Knight's Prolific, the New Prolific, and the Devonshire. These are propagated by grafting upon stocks raised from nuts; and when grafts are taken from bearing wood, fruit may be produced in a couple of years. The tree thrives best on a dry subsoil.

SMALL FRUITS.

The Red, White, and Black Currant, the Gooseberry, the Raspberry, the Strawberry, and Cranberry, are usually cultivated in our gardens, under the title of Small Fruits. Their economical uses in cookery, confectionery, and in the manufacture of home-made wines, attach to them considerable importance, and render desirable a separate account of them, however brief.

The Currant. — The *Ribes rubrum* includes as its varieties our Red and White Currants. The principal subvarieties are:—

Dutch Red, Raby Castle, Wilmot's Large Red, Knight's Sweet Red, Knight's Early Red, Woolly-leaved Dutch, Goodwin's Red, Champagne, Dutch White, Wilmot's New White, Victoria White, which to us appears to be identical with Speary's White, and Pearl White.

Black Currants comprise the Common Black, Black Naples, and Ogden's Black Grape.

Red and white currants are readily propagated by cuttings. They succeed in any sort of common garden soil; but seem to thrive best in warm moist situations, where they enjoy an abundance of air. A few plants are sometimes placed against walls, on which they are trained perpendicularly. They are best when planted in compartments by themselves, and trained as dwarf standards or as bushes, from single stems of about a foot in height, care being taken to prevent the main branches from crossing each other. They are sometimes trained with stems three or four feet high, after the manner of standard Roses. In winter the young bearing wood on the sides of the branches is shortened down into spurs from an inch to two inches in length. The leading shoots are left about six inches long. Some careful cultivators reduce the young shoots to about half their length as soon as the fruit begins to colour, an operation which, in consequence of the more free admission of sun, is found to increase the size and improve the flavour of the berries.

The black currant thrives best in a moist, deep soil and shady situation. Its culture is much the same as that of the the other currants, but the young shoots are not spurred. All the pruning necessary is to keep the branches free of each other, and to promote a succession of young wood.

The Gooseberry.—Botanists distinguish two species; *Ribes Grossularia*, or rough-fruited gooseberry, and *R. Grossularia Uva-crispa*, or smooth-fruited gooseberry. The gooseberry has always been a favourite fruit in Great Britain, and is said to be produced in the middle districts of the island in greater perfection than in any other part of the world. Many very large sorts have originated in Lancashire, where the culture has been carried to a high degree of refinement; but it is to be regretted that *weight* seems, unreasonably enough, to be regarded, in the prize competitions in that duchy, as the *sole* criterion of excellence. Berries of 30 or even 34 pennyweights are boasted of; but such Goliaths are almost always inferior in flavour. The following are some of those sorts recommended in the catalogue of the *London Horticultural Society*:—

Red.—Red Champagne, Ironmonger, Rob Roy, Small Red Globe, Keen's Seedling, Lord of the Manor, Leigh's Rifleman, Red Warrington, Wellington's Glory, Shipley's Black Prince.

Yellow.—Yellow Ashton, Yellow Champagne, Golden Yellow, Smiling Beauty, Smooth Yellow, Yellowsmith, Rumbullion, Sulphur.

White.—Bright Venus, White Champagne, Cheshire Lass, White Crystal, White Damson, Whitesmith, White Honey.

Green.—Green Gascoigne, Pitmaston Green-gage, Langley Green, Late Green, Green Laurel, Gregory's Perfection, Green Walnut, Jolly Tar, Cupper's Bonny Lass.

In forming his collection, the horticulturist should especially select a few early and a few late sorts, and by properly disposing the bushes in various situations in his garden, he may prolong the fruit season by several weeks. The same object may be further promoted by defending the fruit of the late sorts from the attacks of wasps, which is accomplished by surrounding the bushes with bunting (the thin stuff of which ship's flags are often made); and still better with Haythorn's hexagon netting; and also by retarding the ripening of the fruit, which is done by planting the latest sorts against north walls. This last contrivance answers equally well with currants as with gooseberries.

The gooseberry-bush affects a loose rich soil, which readily imbibes, but does not retain, much moisture. Gooseberries, like currants, may be grown in lines or compartments. They are propagated by cuttings, and should be transplanted as early in autumn as the beginning or middle of October. They are trained with single stems, from six inches to a foot high; and all suckers, which are apt to spring up from the roots, should be carefully removed. Formerly it was the practice in Scotland to spur all the annual wood; but now the black-currant system of pruning is more generally and advantageously followed. The ground on which the bushes stand should be slightly forked over once a year, and manure applied, either as a top dressing or else in a liquid form, since disturbing the ground so deep as to cover it in the ordinary manner would be extremely injurious to the roots. No further culture is requisite than keeping down weeds, and preventing the extensive ravages of caterpillars. This last object is best attained by dusting the leaves with powdered hellebore, syringing them with lime or tobacco water, and in many cases covering the surface of the ground with fresh tanner's bark has been found efficacious. Gooseberry plants are sometimes trained on walls or espaliers, to accelerate the ripening, or increase the size of the fruit.

The Raspberry (*Rubus Idæus*) is, like the preceding small fruits, a native of Great Britain. The principal varieties are:—

Red Antwerp, Yellow Antwerp, Barnet, Red Globe, Cornish, Williams' Double Bearing, Belle de Fontenay, Cox's Honey, Franconia, Rivers' large-fruited Monthly, Roger's Victoria, White Globe, White Monarch, Folstaff, which last is the most profitable.

Raspberries are propagated from suckers, which are planted in rows five or six feet apart, and at three feet from each other in the rows. The fruit is produced on small branches which proceed from the shoots of the former year. Every year they throw up a number of shoots or canes from the root, which bear fruit the subsequent year, and then decay. In dressing the plants, immediately after the crop is gathered, all the decayed stalks are cut away, and of the young canes only three or four of the strongest are left, which are shortened about a third. As the stalks are too weak to stand by themselves, they are sometimes connected together by the points in the manner of arches, so as to antagonise and mutually support each other, and sometimes they are attached to stakes. The best support is obtained by fastening the points of the shoots to a slight horizontal rail or bar about four feet high, and placed a foot and a half on the south side of the rows. By this means the bearing shoots are deflected from the perpendicular to the sunny side of the row, and are not shaded by the annual wood. The ground between the rows should never be disturbed by digging. Fresh plantations of raspberries should be made every six or seven years. The double-bearing varieties, which continue to bear during autumn, require light soils and warm situations. It may be mentioned that the crop of any of the varieties may be retarded by breaking off the points of the bearing shoots at an early period in spring; but, like all other fruits, the flavour of the raspberry is highest when it is allowed to ripen at its natural season.

The Strawberry (*Fragaria*) belongs to the same natural family as the raspberry. Amongst the numerous kinds cultivated in our gardens, botanists have distinguished several *species*, but as these distinctions imply no difference in culture, and as it is difficult to trace them amid the sportings of the hybrids, we shall not pretend to enumerate them. Scarcely any plant more readily slides into seminal varieties, the nomenclature of which was a mass of confusion, till revised by Mr Thompson. In the Catalogue of the London Horticultural Society, no fewer than 112 varieties are enumerated; but the following are sufficient, and most worthy of cultivation in any garden:—

Grove End Scarlet is the most proper for preserving, on account of its fine carmine colour; Cuthil's Black Prince, for its early ripening; Myatt's Pine; Elton, on account of its late ripening; British Queen, Deptford Pine, Eleanor, Keen's Seedling, Ingram's Prince of Wales, Princess Alice Maud, Princess Royal, Nicholson's Ajax, Trollop's Victoria, Large Flat Hautbois, White and Red Alpine, Sir Harry, Myatt's Mammoth, and Comte de Paris, allied to the Elton.

The strawberry plant is propagated either from runners or from seed. When runners are employed, they should be taken off as soon as their first rootlets are formed—the sooner the better—and be planted in nursery beds, in well prepared soil, and about seven inches apart. They should be shaded and watered till their roots have been formed, and the plants excited into growth, so as to be strong and well developed the same season. They may be then transplanted either in October or early in November, or the operation may be delayed till March.

Fruit Garden.

By this process a good crop of fine fruit will be obtained the first season.

The desire of new varieties has encouraged the practice of propagating by seed; and Keen, Knevett, Myatt, and others, have been extremely successful. The late Mr Knight having observed that the young runners of the alpine strawberry flower and ripen fruit the first year, was led to adopt this mode of reproduction, and followed it with the happiest success. Early in spring he sowed the seed in flower-pots, which were put into a hotbed; and as soon as the plants attained a sufficient size, they were transplanted into the open ground. They began to blossom soon after midsummer, and continued to produce fruit till interrupted by frost. Thus Mr Knight was inclined to treat the alpine strawberry as an annual plant.

A clayey soil or strong loam is considered as best suited to strawberry plants. On a sandy or very light soil they seldom succeed; and in very close situations, and over rich ground, most varieties produce little else than leaves. Before planting, the ground should be manured and trenched, or digged over deeply, and when stiff and compact it should be very carefully worked. The market-gardeners in the neighbourhood of London grow their strawberries in beds, three rows in each, with an alley between them; while those of Edinburgh plant them in rows two feet asunder, and from a foot to fifteen inches in the rows. High cultivators allow three feet between the rows, and two feet between each plant in the line. When the weather is dry, the young plants are watered till they are well established. In May the runners are cut off, with the view of promoting the swelling of the fruit. During dry weather careful cultivators water their plants after the fruit is set, and occasionally till it begins to colour. The old practice, from which the fruit derives its name, of laying straw between the rows to prevent the soiling of the fruit, has been recently revived; and where there are dressed lawns, the short cut grass may be employed for the same purpose. As soon as the fruit season is over, the runners are again removed; the straw or grass is taken away, and the ground hoed and raked. In October the runners, *but not* the leaves, are cut away, and the surface of the earth is stirred with a three-pronged fork, great care being taken not to injure the roots. Strawberries may be raised from the same ground for an indefinite space of time; but the plants should be renewed every second or third year. They are, however, never so good after the third year, unless the soil is a stiff and rich clay. In the garden they are generally put in a quarter by themselves, and it should be one fully exposed to the sun and air. The alpine and wood varieties may be placed in situations rather moist and shady, or in rows behind walls and hedges, in which situations they succeed perfectly well, and produce fruit late in the season.

The culture of strawberries is the most lucrative part of the employment of the market-gardener, at least near large towns. It is not uncommon for him to realize a clear profit of £25 or £35, or even more, per imperial acre of strawberry ground. The greater the diligence and assiduity of the cultivator, the greater will be his returns. It is a common and just remark, that too little labour is in general expended upon the strawberry, and by the ignorant and unskilful gardener least of all.

Strawberries are extensively forced. Keen's Seedling, British Queen, and Cuthil's Black Prince, are the best. Some cultivators have their plants in a state of preparation for nearly a year before fruit is expected. Others provide new plants for forcing every year. But the same plants may be forced for several successive years, provided they are shifted in August, and, at the time of re-potting, the black torpid roots are cut off, leaving only those of a paler colour, and those which are connected with the new shoots or offsets. Entirely new plants are, however, the best. They should be potted as early in summer as it is possible to procure rooted plants, and encouraged in growth till autumn, by shading till rooted, watering, &c. By the beginning of November they should be placed under the cover of glass pits or frames, to protect them from too much damp, but not to induce them to prolong their growth. By the 1st of January they should be plunged into a mild bottom heat, admitting abundance of air, in order to excite the roots into activity before the tops. When this is effected they are to be placed in a mild temperature in a pit, or on suspended shelves near the roof of a forcing-house close to the glass. After the fruit is set, additional heat may be applied, and during their growth they should be abundantly supplied with water.

Forcing Garden.

THE CRANBERRY.

The American Cranberry grows freely, and produces fruit readily in any damp situation; but where there is a pond, it may be cultivated with the greatest success, if planted around its edges in a bed prepared for the purpose. A layer of small stones is deposited in the bottom, and over these, peat or bog earth, mixed with sand, to the extent of about three or four inches above, and half a foot below the usual surface of the water. Plants of the American cranberry placed on this bed, soon cover the whole surface with a dense matting of trailing shoots. There is a variety which is very shy in yielding its fruit, and this should, of course, be avoided. If the prolific variety be employed, from a bed thirty or forty feet in length, by five or six in breadth, a quantity of berries may be procured sufficient for the supply of a family throughout the year. The fruit is easily preserved in bottles.

The native Cranberry (*Oxycoccus palustris*) may be treated in the same manner, and in some places is very successfully cultivated. At Culzean Castle in Ayrshire, the cranberry ground was surrounded by a ditch, the water of which was made to filter through among stones and stakes to the interior, so as to keep the cranberry plants constantly supplied with moisture. In the same garden a second compartment was dedicated to small fruits of this class, having in the centre a rock-work planted with whortleberries (*Vaccinium Vitis Idœa*), and around the rock-work beds of American Cranberry, of Scottish Cranberry, and of Crowberry (*Empetrum nigrum*), also native.

The following plants produce fruit, some of them abundantly in a wild state, others sparingly in our gardens; but they can scarcely be said to come within the province of Horticulture: *Berberis dulcis*, and other species of Barberry; *Sambucus nigra*, the Elder; *Prunus spinosa*, the Sloe; *P. insititia*, the Bullace; and *Rubus Chamæmorus*, the Cloudberry, with various species of *Vaccinium* and *Gaultheria Shallon*.

THE FORCING GARDEN.

PRELIMINARY REMARKS.

The term *forcing* is strictly applicable only to those artificial processes by which vegetation is in a considerable degree accelerated; but in common language it has been applied to all those operations in which glazed frames or houses are concerned, though they may be employed merely in aiding the common progress of nature, or in counteracting the great vicissitudes of our climate. For the sake of convenience, we shall adopt the term in its broadest acceptation. After some preliminary observations, we shall first treat of the structures, and then of the fruits and vegetables which are cultivated in them.

The principal object of hothouses, and other structures of a similar nature, is to produce an artificial temperature and humidity of the atmosphere, which shall resemble,

Forcing Garden.

as nearly as possible, the climate in which the fruits or plants naturally flourish. A command of heat is obviously a primary requisite. A regulated admission of air, and the presence of a certain degree of moisture, are, in the next place, necessary. Lastly, without the free access of light, plants become blanched, or are destroyed by the moisture which they generate. These, then, are the conditions which limit the form of hothouses; when these are attained, any form may be adopted which invention can devise, or wealth execute; but every true lover of the art will aim at simplicity, and will deprecate useless expenditure, so often exhibited in this department, as injurious to the character as well as to the progress of horticulture.

Artificial Heat.—Forcing-houses are heated in various ways; by means of *flues* conveying smoke and heated air; by *pipes* conducting steam or hot water; by so constructing the glazed house as to increase the calorific action of the sun's rays; and sometimes by the heat generated in the course of the fermentation of vegetable substances.

Smoke flues have been long in use; but they are now very properly almost universally superseded by hot-water pipes. The latter have many advantages over the former. They are far more durable, they occupy much less space, they can be placed in situations where flues can not, they give out a more steady and uniform heat, and can seldom be overheated, they require no repairs or cleaning, and are more elegant in appearance. Flues, on the other hand, are liable to bursting, from the explosions which may arise by the ignition of inflammable gases. Noxious gases cannot be prevented from entering the structure, be the flue ever so well built, and when we consider that these gases consist of sulphurated, phosphorated, and carburetted hydrogen, besides various comparts of nitrogen and carbon, all of which are exceedingly injurious to animal and vegetable life, we need not wonder at the preference given to the one mode of heating over the other. The difference of expense in erection is somewhat more for hot-water pipes than for flues, but they, on the other hand, are the cheapest in the end.

The bricks employed in building flues have, from their soft nature, the property of very strongly absorbing from the air of the house the moisture necessary for the health of plants. Hot-water pipes, on the other hand, being unabsorbent, produce no such effect.

The Furnace.—Very much of the success of all modes of heating depends not only on the construction of the furnace, but also on the working of it afterwards. The most perfect furnace is that which gives the greatest amount of heat from the smallest amount of fuel, and which is capable of being applied to the purposes for which it is intended in the most convenient and most effective manner. Although this has been the study of engineers for above a century, truth compels us to admit that no perfect furnace has hitherto been constructed.

The construction of furnaces, whether for smoke-flues or hot-water boilers, is in principle nearly the same. Hood, an engineer of eminence, and author of the best practical work on heating, observes of furnaces, that "the heat should be confined within the furnace as much as possible, by contracting the farther end of it, at the part called the throat, so as to allow only a small space for the smoke and inflamed gases to pass out. The only entrance for the air should be through the bars of the grate, and the heated gaseous matter will then pass directly upwards to the bottom of the boiler, which will act as a reverberatory, and cause a more perfect combustion of the fuel than would otherwise take place. The lightness of the heated gaseous matter causes it to ascend the flue, forcing its passage through the throat of the furnace, with a velocity proportioned to the smallness of the passage, the vertical height of the chimney, and the levity of the gases arising from their expansion by the heat of the furnace." Tredgold assumed that a furnace for burning a bushel of coals per hour should have a fire grate not less than eight, nor more than sixteen square feet, and the surface of the boiler should be four times the area of the grate, with 32 feet of side flues. This we believe to be considerably more than necessary. Hood, on the other hand, says, in the work already quoted—"Supposing the ordinary kind of furnace bars afford about 30 inches of opening for the air in each square foot of surface measured as the bars are placed in the furnace, and allowing half-inch openings between the bars, where the bars themselves are about 1½ inches wide, then the relative proportions between the area of the bars and the length of the pipe should be as follows:—75 square inches of area of bars will supply 150 feet in length of a 4-inch pipe, 200 feet of a 3-inch pipe, and 300 feet of a 2-inch pipe; 100 square inches of area of bars will supply 200 feet of a 4-inch pipe, 266 of a 3-inch pipe, and 400 feet of a 2-inch pipe; 150 square inches of area of bars will supply 300 feet of 4-inch pipe, 400 feet of a 3-inch pipe, and 600 feet of a 2-inch pipe, and so on in proportion.

All the air necessary for causing combustion of the fuel should be made to enter from below, that is, through the ash-pit, and not through the door or sides of the furnace, as by so doing it becomes heated to between 900° and 1000° before it comes in contact with the fuel. To produce this effect it is necessary to have double furnace doors and ash-pit registers, the first suggested by Dr. Black, and the latter by Count Rumford. By such arrangements only can the gardener have control over his furnace, for by shutting up the ash-pit and furnace door closely combustion is lessened, and the fire may be kept almost in a state of suspension for many hours together; while, on opening either the door or ash-pit register, air is admitted and combustion goes on.

Smoke-consuming Furnaces.—The attention of modern inventors has of late years been very properly directed to the consumption of smoke. That of Witty, or rather of Chanter, was amongst the first, and has been found to work well for garden purposes. The very best constructed furnace will not work satisfactorily, unless proper attention is paid to it by the fireman. A vertical section of Witty's furnace is given in fig. 15. The fuel is supplied by the door at *a*, and is pressed down the inclined plane towards the grate, *c*, by a screw placed at the head of it (but this method has given way to the use of the common tools used for feeding furnaces); *b* is the door for regulating the fuel on the grate *c*. In its progress the whole surface of the coal along the inclined plane is constantly kept in a state of inflammation, the flame having naturally a tendency to burn upwards. In this way the greater part of the fresh coal is carbonized, that is, the gas is separated from it and inflamed, leaving only coke. The strong combustion of the coke at the grate produces heat

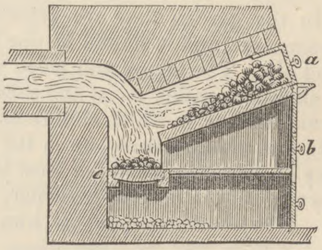

Fig. 15.

Forcing Garden.

Forcing Garden.

enough to carbonize the coal, and air enough to inflame the gas. This furnace, therefore, not only consumes most of the smoke, but effects a considerable saving of fuel. The principal smoke-consuming furnaces adapted to garden purposes are, Williams' improved or argand furnace, that of Mr Wye Williams of Liverpool, and Mr Joseph Williams of the same city. Experiments made as to the action of the latter have shewn that in the front flue of a furnace of common construction the thermometer seldom rose above 1100°, and often fell below 900°, the mean being 975°; while in the same furnace, while consuming its smoke upon Mr Williams' principle, the mean temperature was 1160°, ranging between 1400° and 1000°.

The consumption of smoke not only economises fuel to a very considerable extent, but also prevents surrounding buildings, &c., being discoloured by the escape of unconsumed carbon.

Steam as a heating medium has been so completely superseded by hot water for all horticultural purposes, unless it may be in cases where the waste steam of manufactories, &c., may be turned to account in some adjoining garden, that our observations on it here will be brief. The first expense of a steam apparatus, its expense of maintenance, and liability to get out of order, are some of the principal objections to its use. It is also less uniform and certain in its operation. This is explained by the high authority of Hood, who says, "The weight of steam at the temperature of 212°, compared with the weight of water at 212°, is about as one to 1694; so that a pipe which is filled with water at 212°, contains 1694 times as much matter as one of equal size filled with steam. If the source of heat be withdrawn from the steam-pipes, the temperature will soon fall below 212°, and the steam immediately in contact with the pipes will condense; but in condensing the steam parts with its *latent heat*, and this heat passing from the latent to the sensible state, will again raise the temperature of the pipes. But as soon as they are a second time cooled down below 212°, a further portion of steam will condense, and a further quantity of latent heat will pass into the state of heat of temperature; and so on until the whole quantity of latent heat has been abstracted, and the whole of the steam condensed, in which state it will possess just as much heating power as a similar bulk of water at the like temperature, that is, the same as a quantity of water occupying 1-1694, the part of the space which the steam originally did." It has also been proved that a given bulk of steam will lose as much of its heat in one minute as the same bulk of water would in three hours and three quarters.

Hot Water.—Heating by causing hot water to circulate in iron pipes or vessels was brought into notice in 1827, and may be said to have now superseded all other modes of heating whatever, which is a sufficient proof of its superiority. For several years after its invention the true cause of the circulation of the water in the pipes was misunderstood; nor was it till the publication of Mr Hood's "Treatise on Heating, &c.," that this was explained. The erroneous opinion of Mr Tredgold, which has found its way into many standard works, requires to be noticed. This can, however, best be done by quoting Mr Hood's own words—"Let us suppose heat to be applied to the boiler *A* (fig. 16); a dilatation of the volume of the water takes place, and it becomes lighter—the heated particles rising upwards through the colder ones, that sink to the bottom by their greater specific gravity; and these in their turn become heated and expanded like the others. This intestine motion continues until all the particles become equally heated, and have received as much heat as the fuel can impart to them. But as soon as the water in the boiler begins to acquire heat, and to become lighter than that which is in the opposite vessel *B*, the water in the lower horizontal pipe *d* is pressed by a greater weight at *z* than at *y*, and it therefore moves towards *a* with a velocity and force equal to the difference in pressure at the two points *y* and *z*. The water in the upper part of the vessel *b* would now assume a lower level, were it not that the pipe *c* furnishes a fresh supply of water from the boiler, to replenish the deficiency. By means of this unequal pressure on the *lower* pipe, the water is made to circulate through the apparatus, and it continues to do so, so long as the water in *B* is colder, and therefore heavier than that which is in the boiler; and as the water in the pipes is constantly parting with its heat, both by radiation and conduction, while that in the boiler is as continually receiving additional heat from the fire, an equality of temperature never can occur; or else, if it did, the circulation would cease. We see then that the cause of circulation is the unequal pressure on the lower pipe of the apparatus, and that it is not the result of any alteration which takes place in the level of the water," as erroneously stated by Tredgold, Atkinson, and others.

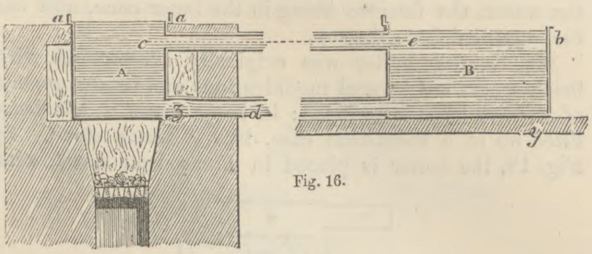

Fig. 16.

Fig. 16 referred to in the preceding quotation, representing the common tank boiler, surrounded by a flue, with a cistern at the extremity of the pipes, exhibits the form in which the apparatus was first erected; but as in this arrangement the process of heating was very slow, many changes have been made; the cistern has generally been abandoned, and boilers of various configurations have been adopted. Fig. 17 is a longitudinal section, and Fig. 18 is a transverse section of a fluid tank boiler, in which the surface exposed to the heat being increased, the effect required is accelerated, and at the same time a considerable saving of fuel is effected.

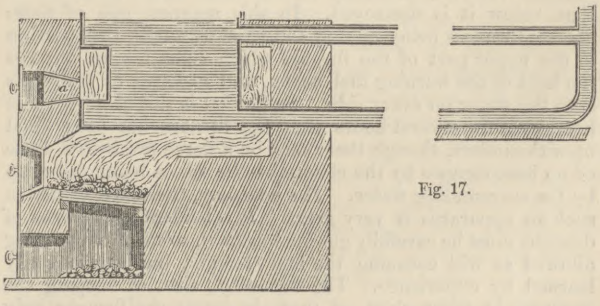

Fig. 17.

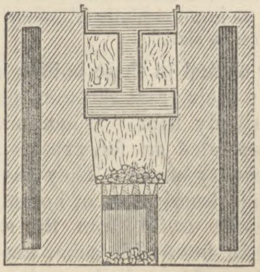

Fig. 18.

Forcing Garden.

Forcing Garden.

The conical boiler, invented by Mr Rogers, of Seven Oaks, Kent, is formed of two truncated concentric cones, with a space of two or three inches between them for the water, the furnace being in the inner cone, and the fuel supplied from the top.

Mr Rogers' boiler was originally surrounded with brick-work, but several modifications and improvements of it have been introduced: in some cases it has been fitted up in a sheet-iron case, like Arnott's stove. In Fig. 19, the boiler is placed in a cast-iron stand, with ground circular furnace, and register ash-pit doors,—*a* being the furnace, *b* the boiler, *c* flow and returning pipes, *d* the furnace door, *e* smoke-pipe to the vent, *f* ash-pit, *g* grating, *h* hole for cleaning the furnace. The best kinds of fuel for this furnace are coke, gas-cinders, and anthracite; but common coal which does not cake very much has been found to be well adapted for the purpose, as it is soon formed into coke.

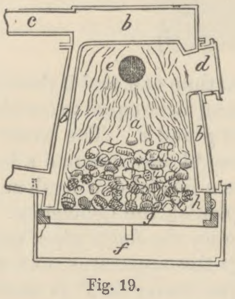

Fig. 19.

The following is the *rationale* of the process of the heating of this boiler, as given by Mr Rogers in the *Gardener's Magazine*:—

> "As fuel cannot be consumed without air, if a furnace be constructed of considerable depth, and filled with fuel, and air be admitted only at the bottom, that fuel alone is consumed which lies immediately on the bars, and first receives the draught of air. The fuel above, provided it transmits the air, becomes red-hot, or nearly so, but does not consume until that below it is destroyed. In this manner, one of these conical furnaces being lighted and filled with fuel, that portion in the upper part of the furnace which cannot burn absorbs the heat of the burning fuel below, and radiates or transmits it to the water on every side. So perfect is this absorption of heat, that for several hours after the furnace has been filled up with cinders, though there may be a fierce fire below, little or no heat escapes by the chimney—the whole being taken up by the surrounding water. The economy, therefore, of fuel in such an apparatus is very great. It is evident that excess of draught must be carefully guarded against, so much only being allowed as will consume the fuel steadily, but this is easily learned by experience. The necessity, also, of keeping the aperture in front close, so that air enters the furnace only through the ash-pit, is hence evident. The water (as may be observed from the above figure) is in close and immediate contact with the red-hot fuel on all sides, no black smoking coals intervening, as in most kinds of boilers; hence the great power in proportion to size."

The economy of fuel in these boilers is not their principal advantage; their great recommendation is a long-continued and steady heat. When properly managed, they may be depended on for preserving the heat for from fifteen to twenty hours. They have been successfully applied to all descriptions of hothouses, but for pits they are eminently useful from the small space they occupy; and when fired with coke, gas-cinders, or anthracite, they give off very little smoke.

The number and variety of forms recommended for boilers are now very great, although many of them, it will be admitted, are of no practical utility. The simpler the form and least complicated the whole apparatus the better, at the same time, those forms are the best that present the greatest surface to the action of the fire, such as Bailey's (fig. 20); and Cottam and Hallen's (fig. 21) boilers, which of themselves form the dome (fig. 22) or roof of the fire-place, having the fire burning below them and round their sides, are valuable in that respect. Burbridge and Healey's fluted boiler presents a larger surface to the flame than a plain surfaced one of the same dimensions; and Weeks and Co.'s tubular boiler possesses this merit in an eminent degree.

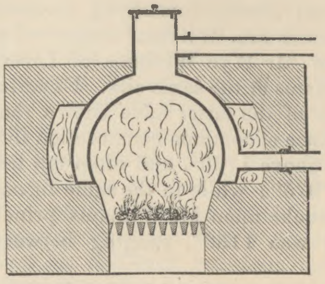

Fig. 20.

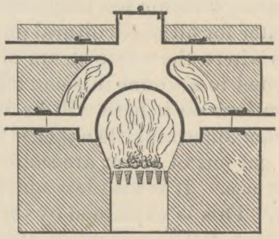

Fig. 21.

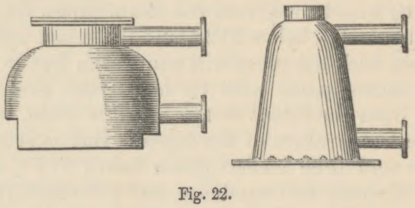

Fig. 22.

Boilers constructed so that several hothouses may be heated by one fire, deserve attention, as they are more conveniently wrought, and are less expensive than having stop-cocks or valves placed upon the pipes at various distances from the boiler. In practice we have found Waldron's boiler (fig. 23) to work well. As will be seen by the diagram, the hot water from the boiler rises in a vertical pipe, and flows into an iron box fixed on its top, from which issue as many pipes as there are houses or pits to heat, allowing one pipe for each. Each of these pipes is furnished with a stop-cock, by which the water is turned off or on as may be desired. The return pipes are all connected with a similar box fitted to the end or side

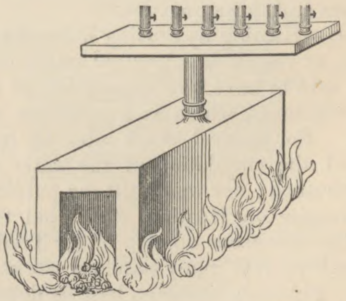

Fig. 23.

of the boiler, and from it through a single pipe the cold water enters the boiler near its bottom.

Connected with this distribution of heated water is Critchley's patent heat-regulator, figs. 24, 25. It is placed a little on one side of the boiler, and to prevent the loss of heat by radiation should be enclosed within double walls of brickwork.

It is unnecessary to describe all the numerous modifications of this apparatus; but it may be proper to direct the attention of the reader to the close boiler represented in fig. 26, in which is shewn how the circulation may be conducted over a door or other obstacle. In this case the upper pipe must not ascend and descend twice: air-tubes ought also to be placed in the boiler, and on the highest part of the pipes; and the whole must be made considerably stronger than on common occasions, to resist the pressure.

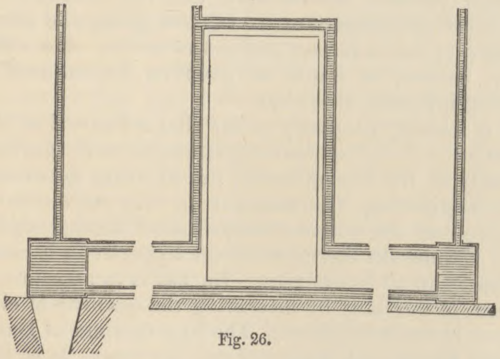

Fig. 26.

To cause heated water to descend below the level of the boiler, by carrying it under a passage (which should be avoided if possible), it is necessary to raise the water, as it is heated, to as great a height above the boiler as it is intended to carry it below it. This depression must take place once only

In the early stages of this mode of heating, flat pipes were used for the flow or upper range of pipes, from a mistaken idea that they presented a greater radiating surface than round ones of the same calibre. These are now abandoned, and both flow and return pipes are made cylindrical. The number of pipes must be regulated by the extent to be heated, and the degree of temperature required. Hence it is often well to have three or even four upper or flow pipes, and only one under or return pipe. As to size, 4-inch pipes are almost universally employed.

As to position, they should be placed near the front or lowest part of the house, and should, to prevent loss of heat by conduction, be supported clear of the ground, upon cast-iron chairs, so as to clear them of the borders not less than six inches.

An ingenious mode of heating has been shown by Mr. Fowler in his tract on the Thermosyphon, as he calls it, by which he has shown how walls, as well as glass-houses, may be heated. He says, "Any one may prove that hot water will circulate in a syphon, by taking a piece of lead pipe, say of half an inch bore, and four or five feet long, bending it like a syphon, but one leg a good deal more bent than the other, in order to give the descending water time and space for giving out its heat; and then, filling this tube with water, and placing one hand on each end to retain it full, immerse the extremities in a pot of water over a fire, as represented in the annexed fig. 27. Supposing the water of a uniform temperature in both legs of the syphon, no circulation would take place; but supposing it to cool sooner in the long leg *a* than in the short leg *b*, then the equilibrium would be destroyed, and the water in the long leg *a* would descend, and draw up water through the short leg *b*; and this circulation would continue as long as the water *c* was maintained at a temperature above that of the surrounding atmosphere."

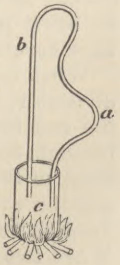

Fig. 27.

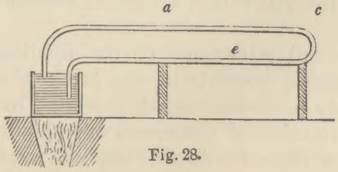

Fig. 28.

Mr Kewley's adaptation of the syphon is one of the simplest and most efficient that has been proposed. In

Forcing Garden.

fig. 28, *a*, *c*, *e*, are the two legs of a syphon, through the upper of which the heated water ascends, and by the lower descends. Immediately over the descending bend, a pipe connected with an air-pump is inserted, in order to fill the pipes, or remove the air which collects in the superior limb. Instead of the air-pump, a funnel with air-tight valves is sometimes employed.

Hot water may be beneficially applied to garden-walls, whether they are covered with glass or not. To this end the walls must be built hollow, and the pipes placed near the bottom of the cavity, and supported on cast-iron chairs placed on the top of the foundation course of material. This method was first exemplified by Mr Atkinson in the gardens of the Duke of Bedford at Wolburn Abbey in 1828. The most extensive application of the principle is to be found in the gardens of the Duke of Buccleuch at Dalkeith House, where the whole of the principal brick walls are heated in this manner.

Mr Perkins has constructed an apparatus of small tubes hermetically sealed, in which water circulates, of a temperature varying from 300° to 400° Fahrenheit. The contrivance is very ingenious, and has been pretty extensively employed in London and Edinburgh, in heating public offices and warerooms. It is not, however, adapted to horticultural purposes. For further information we may refer to M'Intosh's *Book of the Garden*, in which above 250 illustrations of various methods of heating are given; and for the principles of heating, to "Hood's Treatise on Heating and Ventilation," *new edition*, "Tomlinson on Warming, &c." "Bernan's History of the Art of Warming and Ventilating, &c."

Mr Corbett introduced what has been called the gutter mode of heating. From a common boiler proceeds an upright tube, and this tube leads to a continued series of open gutters. Heat being applied to the boiler, the water rises in the tube and flows forward in the gutters, giving out moisture in proportion to the degree of heat. As the water cools or becomes more dense, it gradually falls back to the bottom of the boiler, through a connecting pipe.

Mr Rendle, of Plymouth, has also introduced a mode of heating, in which he employs tanks instead of pipes, or gutters, for both surface and bottom heat. These tanks are formed of wood, brick, stone, or cast-iron. When formed of wood, they require to be made of good sound plank, not less than two inches thick, properly jointed, and are usually covered with slates. If they are formed of stone or brick, the insides require a thick coating of Roman cement, and for covers, stone, slate, or brick pavement is employed. The cast-iron tanks have covers of the same materials.

When only one tank is fitted up in a house or pit, a division is made along the centre, leaving an opening at the end farthest from the boiler, for the water to flow through, the hot water or flow pipe from the boiler being fixed to the end of the tank, on one side of the division, and the cold water, or return pipe to the boiler, being fixed to the end on the opposite side of the division. When two tanks are used, they are joined to the flow and return pipes respectively, and united at the extreme ends. In pits, the tanks may be carried round the sides and ends of the pit, with a division between the flow and return pipes.

The principal advantage of the application of this mode of heating consists in the production of bottom heat. Proper provision ought, however, to be made for preventing no more of the steam or vapour rising from the hot water (into the house) than is requisite; for, if this precaution be not adopted, there will be too much damp in the winter season for the proper growth or preservation of the plants.

Forcing Garden.

The rays of the sun, especially by being reflected from walls and other surfaces, become a source of artificial heat. This species of heat, however, is materially affected by the admission of the air necessary to the growth and healthy state of the plants. Solar heat, if properly regulated by ventilation, is of immense importance in the ripening of many of our finer fruits. In the orchard houses recently brought into notice by Mr Rivers, fruits are ripened by the influence of solar heat alone. The idea is, however, by no means new. We have known many glass houses in which peaches and grapes have ripened in the greatest perfection, without any other heat than that from the sun. Mr Rivers' orchard houses are by far too small, and of too temporary a character. They should be permanent structures, covering a considerable space, and, at the same time, must be kept low. The management of the temperature consists solely in the proper regulation of the ventilators, securing as much solar heat during the day as possible, ventilating early in the morning, and shutting up early in the afternoon.

The use of vegetable substances in the production of heat, is rapidly disappearing from our best gardens before the application of hot water, which is far more economical and certain in its effects.

In the management of artificial heat, a considerable degree of caution is required. All the operations of nature are gradual; and in *forcing*, it is well to follow these as the safest examples. The judicious gardener will therefore apply his heat very gradually at first; he will increase it by degrees for several weeks, and, in particular, he will guard against any sudden decrease of warmth, as nothing is more necessary to success than that the course of vegetation be continued uninterruptedly through foliation, inflorescence, and fructification. He will cause the temperature to *increase by day* and *decrease by night*, to *rise in summer* and *fall in winter*. He will, in short, imitate, as much as possible, the natural and varying influence of the sun.

It is scarcely necessary to say that a Fahrenheit thermometer is an indispensable instrument to the gardener, not only in the forcing-house, but in every department. Six's Registering Thermometer is very convenient for pointing out the extreme temperatures during night or day. Besides the thermometer the hygrometer is equally necessary in all hot-houses. Its use is to ascertain the degrees of humidity by measuring the quantity of elastic vapour in the atmosphere. The hygrometers of Daniell, Mason, Leslie, and Simmons are the best. It is justly remarked by Dr Lindley, in his *Theory of Horticulture*, that "skilful balancing of temperature and moisture in the air, and a just adaptation of them to the various seasons of growth, constitute the most complicated and difficult part of a gardener's art. An excess of dampness is indispensable to plants in a state of rapid growth, partly because it prevents the action of perspiration from becoming too violent, and partly because, under such circumstances, a considerable quantity of aqueous food is absorbed from the atmosphere, in addition to that obtained by the roots. But it is essential to observe that, when not in a state of rapid growth, a large amount of moisture in the air will be prejudicial rather than advantageous to a plant; and if the temperature is at the same time high, excitability will remain in a state of continued action, and that rest which is necessary will be withheld, and the result of which will be an eventual destruction of the vital energies. But on the other hand, if the temperature is kept low while the amount of atmospheric moisture is considerable, the latter is absorbed

Forcing Garden.

without its being possible for the plant to decompose it."

The Admission of Air.—The deteriorating influence which all living plants are supposed to exert on the atmosphere, must operate with tenfold force in a glazed house, where the proportion of air to vegetable substance is infinitely smaller than under the open sky, and where the corrective agitations of the wind, and the changes of temperature, are much less perceptibly felt. The respiration of plants, and the exhalations of putrescent vegetables, require a constant circulation of the aerial fluid, and this is maintained by means of moveable ventilators in the roof and walls of the house.

The best modes of securing a proper amount and equal distribution of air in hothouses, we may as well add in dwelling-houses also, has until lately been little understood. "All ventilation is founded upon the simple principle that cold air is heavier, and has a tendency to sink downwards, while hot air is light and rises to the top. At first sight it may appear that for the purpose of ventilating any building, it is only necessary that holes should be made at the bottom of the apartment for the air to enter, and other holes be placed in the upper part, for the hot air to escape. Practically, however, ventilation is far from being so simple an affair."—(*The Book of the Garden*, vol. i. p. 271.) Plants in the open atmosphere are constantly surrounded with air, which is itself incessantly in motion, and this motion is increased during the night, the time when they are feeding most especially. "The atmosphere," as Dr. Lindley rightly expresses it, "is their pasture, and its ever varying density is a natural phenomenon most intimately connected with the maintenance of vegetable health. It is a beautiful compensation for their want of locomotion; as plants cannot move to the atmosphere, the atmosphere is ever moving towards them. It is therefore certain, without inquiring into the exact philosophy of the matter, that free access of abundant air must be secured, if the health of plants in glass houses is to equal that in the open air."

To secure this important end, it will be necessary to abandon the means, hitherto almost invariably in use, namely, by throwing open the sashes, whether at the top of the house or in front. The sliding down of one sash over the other, as in the former case, greatly augments the shade in oblique sunshine, a glimpse of which we can ill afford to spare in our cloudy atmosphere, and in the latter case the openings being opposite the tender foliage are hurtful to it, particularly when the external air is, as it often is, many degrees below that of the internal.

Fixed roofs should therefore be adopted, and ventilation effected by bringing in fresh air through the parapets, and so close to the floor that it cannot reach the plants in a direct manner. The vitiated or exhausted air should be made to escape through the apex of the ridge.

Most commonly, air is given only during the day, and is excluded at night, with—as is too often the case—an increase of fire-heat. Judicious horticulturists should always reverse this process, since in all countries chilly and cold nights usually succeed the hottest days, and plants require air by night as well as by day.

An injudicious admission of air is often attended with consequences as bad as its almost total exclusion. Cold, dry air, admitted into a glass-house in which the air is moist, and at a much higher temperature, has the effect of abstracting from the plants and the soil in which they grow a great part of their moisture, and thus producing a very injurious effect upon their constitution. The rapid evaporation too, which takes place by the admission of cold, dry air, produces a degree of cold upon the leaves, which, although not measurable by instruments, produces an effect somewhat analogous to the chill experienced by persons sitting in a warm room and exposed to the cold draught from the door or window.

To remedy this defect in ventilation, what has been called of late years aëration, or subterranean ventilation, has been adopted. This is effected by bringing in supplies of fresh air through tubes or drains placed several feet under the surface of the borders, and having one end opening into the open air, while the other opens through various parts of the floor or border, and often very properly under the hot-water pipes. By this means we admit fresh air at almost the same temperature as that of the air, close to the front of the house, and also charged with the moisture which it receives in passing through the damp pipes or drains.

Air admitted in this manner is often beneficially allowed to operate during the night as well as during the day. For plants, like animals, cannot long exist without their necessary supply of that element by night as well as by day.

The Admission of Light.—In addition to the heat with which natural light is always accompanied, it seems to possess another property necessary to vegetation, which, from some cause hitherto unexplained, is partly deranged by its transmission through glass. This fact, though strange, is evident from the circumstance that though the intensity of light is apparently undiminished, plants thrive better near the glass than at a distance from it. The distance from the glass at which this phenomenon takes place has never been determined, although it is an optical problem, the solution of which would be of much importance to the garden architect. The amount of solar light which plants in glass-houses require for the fullest development of their various parts is probably more than even our best hot-houses transmit. Certainly it is much greater than is transmitted through the roofs of houses as generally constructed. Let us first see the beneficial effects of light on plants placed under such circumstances, and then consider how it can be best insured. "It is the property of solar light, when striking upon the leaf of a plant, either directly or indirectly to cause—First, a decomposition of carbonic acid; secondly, an extrication of oxygen; and thirdly, invisible perspiration. By their vital forces plants appear to decompose water, independently of the action of light. Carbonic acid is originally introduced into the interior of a plant, either dissolved in the water it imbibes by its roots, or by attraction from the atmosphere, or by the combination of oxygen—resulting from the decomposition of water or from other sources—with the carbon in its interior. When a leaf is exposed to the direct influence of the sun, it gives off oxygen by decomposing the carbonic acid; whereupon the carbon remains behind, in the interior of the leaf, in a solid state. In the total absence of solar light, there is little or no extrication of gaseous matter, and what little is given off will be found to be carbonic acid, which plants exhale at all times in small quantities; oxygen, however, which was before expelled, is inhaled. Hence plants decompose carbonic acid during the day, and acquire it again during the night, and, during the healthy state of a plant the decomposition of this gaseous matter by day, and its recovery by night, is perpetually going on. The quantity of carbonic acid decomposed is in proportion to the *intensity of light* which strikes a leaf, the smallest amount being in shady places; and the healthfulness of a plant is, *cæteris paribus*, in proportion to the quantity of carbonic acid decomposed; therefore the healthiness of a plant should be in proportion to the *quantity of light* it receives by day."—*Theory of Horticulture.*

Can we, therefore, with glass-houses constructed as they have generally been hitherto, secure light, if not to its fullest, at least to its necessary extent? Certainly not. Nor can we expect it with so large a proportion of their surfaces rendered perfectly impervious to light, with dead walls, massive rafters, framed sashes, and inferior glass, inserted in small fragments with numerous overlaps, and either cross-puttied or filled with dust or muscoid matter. The calculations made in regard to obscurity occasioned by the above, irrespective of solid walls, amounts to 10 feet taken up with laps choked with dirt out of every 60 superficial feet of glazing, and from 18 to 20 feet of unnecessarily heavy timbering and multiplicity of astragals. Hood, in making his calculations of the loss of heat by radiation in glass-houses, arrives at pretty nearly the same conclusion. He estimates the surface of wood alone at an eighth of the whole roof, and adds, that in the generality of horticultural buildings, the wood work fully amounts to this quantity.

Connected with the admission of light, is the determination of the pitch or angle of elevation of the roofs of glazed houses. It is evidently of advantage that the rays of light should fall upon glass perpendicularly, as loss by reflexion is then a minimum, or indeed little or nothing. The angle necessary to obtain this result is easily deducible from the sun's place in the ecliptic. At the equinoxes, the sun's meridional height above the horizon at any point of the earth's surface is equal to the complement of the latitude of that place: and hence, in order that the sun's rays may be perpendicular at that period, it is only necessary to make the elevation of the roof of the hothouse equal to the latitude of the place. The angle, for any other season, may be obtained by subtracting from the latitude the declination of the sun, if at that time to the north of the equator, or by adding it, if to the south.* These periods are of course selected in accordance with the time at which the direct rays are most required. Mr Knight proposed a general elevation of 34° for the latitude of London, an angle which corresponds to the 20th of May and 21st of July. This would afford four months, from the 20th of April to the 21st of August, during which the angle of incidence at mid-day would not at any time amount to 9°, while the deviation at the winter solstice would be 43°, and the loss of light from reflexion would be little more than $\frac{1}{30}$. The Rev. Mr Wilkinson recommended 45°, a pitch extremely suitable for early vineries and pine-stoves. In this case, the midsummer deviation would be 19°, and the loss $\frac{1}{40}$, and the midwinter deviation 30°, while the loss is nearly the same. From these statements, however, it is manifest that much greater exactness has been sought in this matter than is at all necessary. The reduction of the opacity of the roof, arising from the breadth and depth of rafters and astragals, is of much greater consequence. Accordingly, the best hothouse builders now construct these roofs, whether of metallic substances or timber, entirely without rafters or framed sashes, and only use glass of the best quality, and in panes 12 inches in breadth at least, and from two to four feet in length.

Hothouses are in general constructed of the best Baltic pine timber, and unless they are of gigantic dimensions, this material is found to answer better than any other. Metallic structures are far more expensive in their erection, and are liable to great and sudden changes of temperature on account of their being both conductors of heat and cold, whereas timber is a non-conductor of both. The relative difference in cost between metallic and wooden houses, may be taken in ordinary cases as two to one, and in many cases as three to one.

In order to secure the greatest possible influx of light, some scientific horticulturists recommend hothouses with curvilinear roofs. It was remarked by Sir George Stuart Mackenzie, to whom the merit of the proposal is primarily due, that if we could find a form for a glass-roof, such that the sun's rays should be perpendicular to *some part of it*, not on two days, but during the whole year, that form would be the best. Such a figure is the sphere, and he therefore proposes a quarter segment of a globe, or semidome, the radius of which is about fifteen feet.

This form of hothouse roofs was warmly patronised by the late Mr Knight, who, however, was of opinion, that the house proposed by Sir George Mackenzie was too high, in proportion to its length and breadth, and therefore recommended a smaller section of a sphere, with a greater radius. His dimensions are forty feet long, fourteen wide in the centre, and, including the front parapet, twelve feet high. The late Mr Loudon, who, it is believed, was the first that actually erected hothouses on this principle, proposed several sub-varieties of form. He describes, in his "Encyclopædia of Gardening," the *accuminated semidome*, the *accuminated semiglobe*, the *semi-ellipse*, and the *parallelogram with curved roof and ends.*

As far as we are aware, no very satisfactory experimental investigation of the *comparative* merits of curvilinear houses has hitherto been made. A writer in the "Gardener's Magazine" (vol. ii.) states, that he found it necessary, during the summer months, to shade his pine-apples growing in such a house, from nine or ten o'clock in the morning, to three or four in the afternoon, in order to prevent the plants from assuming a rusty tinge, and unhealthy appearance. Another practical gardener complains (vol. v.), that "the circular roof concentrated the sun's rays so immoderately, that the tops of the vines were actually scorched, even when the doors and ventilators at the back were all open. This was always the case in summer; and in winter, it was with the greatest difficulty, and only with the assistance of mats, that they could keep out frost; the thermometer frequently indicating only 40° when strong fires were burning." A considerable portion of the superior lightness of the curvilinear houses is due to the absence of rafters, and as these may also be dispensed with in plain roofs, the effect of these ought to be deducted in making a comparison. Span, and ridge and furrow roofs are now the prevailing forms. Amongst the advantages of these forms is their admission of the greatest amount of light which our climate affords, especially when they are glazed to within a few inches of the ground. The former should always be placed with their ends towards the south and north, and apart from walls and all opaque surfaces. The latter has the advantage of being carried (without sustaining walls) to any extent of area, even whole gardens may be thus covered in—the internal columns of support being neces-

sary at the same time for conducting the rain water off the roof to underground drains or reservoirs. Indeed, it has been proposed to support such roofs to a great extent upon suspension principles. Any form is better than that of the *lean-to*, both for internal arrangement as well as effect.

Since the repeal of the duty upon glass, small panes have been disused, and glass not only of much larger size, but of greater strength and better quality is now always employed. The advantage of this is the greater admission of light, an element of all others over which we have the least control. The greater the surface of glass, and the less space is occupied by rafters and astragals, as well as overlaps, the better; for these latter, whether cross-puttied or not, all tend to the exclusion of light. The height of such structures has also a good deal to do with the healthy development of vegetable life, as the rays of light pass so as to be beneficial to plants only to a supposed distance beyond the surface of the glass, but what that distance is, appears not to have been very accurately determined. This is the more extraordinary, for while it is universally admitted that the heat of the sun is the cause of growth, and also that light is the cause of maturity in the vegetable kingdom, no one has said whether the beneficial effects of light extend to the distance of six inches or sixty feet beyond the inner surface of the glass, or at what intermediate distance it is most effective.

In closing these preliminary remarks, it is proper to observe, that although the construction of a forcing-house is always a matter of considerable importance, it is not the only, nor even the most important condition necessary to insure success. Much care in management, skill in pruning, and knowledge in physiology must be possessed and applied, in order to obtain abundant and regular crops of fine fruit.

The more minute details respecting the structure of glazed houses, we shall notice along with the peculiar culture required in each; and we shall take them in the following order:—The Vinery, the Peach-house, the Cherry-house, the Fig-house, the Pinery, the Orangery, and the Melonry. The greenhouse and other botanical structures, will come more appropriately under review in treating of the Flower Garden.

The VINERY. *Structure.*—The vinery is susceptible of great variety of form; and, indeed, in this respect, seems more pliable than any other forcing-house. That form, however, which has been most commonly used, till of late, is the plane roof with sliding sashes, of which fig. 29 is offered as an example. Span-roofed houses are now preferred, as affording a greater surface for training the vines to, being more elegant in form, and constructed at a much less expense, that is, presuming that the back wall has to be built. Fig. 30 is an example of this form. The parapet walls all round are supported on a foundation wall piered and linteled over just under the surface line. The parapets themselves consist of a base course of ashlar 12 inches thick each way. The stone piers 18 inches in height, and a foot thick, are placed 3 feet apart, the spaces between being filled with glass ventilators, made to open and shut simultaneously. A cope 6 inches in thickness is placed on the top and upon this the superstructure rests. The sides and roof are of glass and fixtures, but without rafters or framed sashes. The top ventilation is secured by the sides of the lanthorn top being furnished with gun-metal rollers, and made to slide upon an iron rail. The vines are planted within, and trained to a trellis under the roof, sides, and ornamental arched supports, as shewn in the cut. An ornamental cast-iron grating forms the passage which runs along the centre of the house. In the case of span-roofed vineries, double the breadth may be given, and where hot water is employed instead of flues, several such houses can be heated by the same fire. The trellis used for training is generally formed of wires drawn across the roof, at the distance of a foot from each other, and 18 inches from the glass, and attached to iron ribs placed under it. Sometimes the trellis is placed vertically, but this is more appropriate for the peach-house than the vinery. This form, exhibited in fig. 31, is called the hanging trellis. It must, however, be admitted that, according to the experience of some, this arrangement is inferior to the common trellis, that is, so far as vines are concerned.

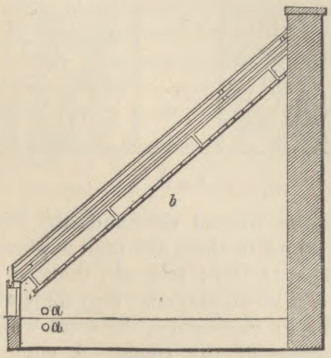

Fig. 29.

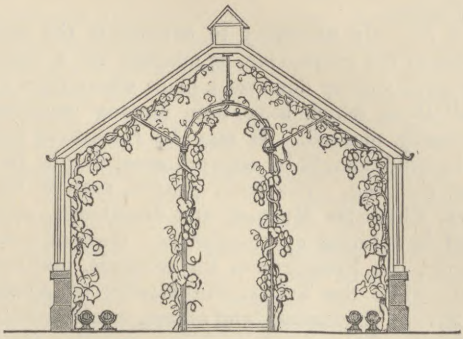

Fig. 30.

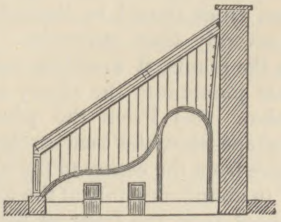

Fig. 31.

Forcing Garden.

It is of importance that the included soil and front border of a vinery should be fresh and rich. It should not exceed 2½ feet in depth, and should be laid over a vaulted foundation, or one rendered perfectly dry by drainage, and all borders of forcing-houses should be elevated in height equal to their depth above the general ground level. The soil is of far less consequence than a dry bottom, and the following is as good as any—"one-half of good loamy soil with its turf, one quarter of rich old dung, and one quarter of brick and lime rubbish; the turf well rotted, and the whole well incorporated." Plants raised from eyes, and prepared for two years in pots, are preferred for the furnishing of a vinery; and when planted inside the house, there should not be fewer than two plants to each four feet of space.

It is scarcely necessary to enumerate the particular varieties of the grape-vine, as adapted for a vinery, for every good variety deserves a place where there is room, and all those which have been already mentioned are occasionally planted. It may be remarked, however, that the kinds should be assorted according to the order of their ripening. The early grapes, such as the Muscadines, Chasselas Musqué, and Hamburgs, should be planted in a house by themselves; those of a medium character, the Frontignacs, for example, may occupy a second; while the Tokay, the Muscat of Alexandria, Nice, Syrian, Barbarossa, and others, would be fit inmates for a third. This would produce a regular succession, and admit a uniformity of treatment in each house. Where there is not a suite of vineries, but only one large house, the late varieties should be planted near the entrance of the hot-water pipes.

Pruning and Training. Very numerous have been the directions given in reference to these particulars; but we cannot here go into such details, nor is it necessary. The great object is the reproduction of bearing, that is, annual wood, over the whole surface of the house. When this is accomplished, the next matter to be determined is the number of eyes or buds to be left on each shoot, that is, whether we shall adopt the *short* or the *long* system of pruning. The former is most allied to the practice of foreign vineyards, and has been most successfully employed in this country. According to this method, all the lateral shoots are cut down to single eyes, as described in *Lond. Hortic. Trans.* iv. 104. For a particular description of the *long* system, we refer to the same vol., or to "London's Encyclopædia of Gardening." To these references we add a few general remarks. (1.) In this country, it ought to be the great aim of the gardener to make his vines grow as luxuriantly as possible; for the quality of the grapes, when properly ripened, is generally commensurate with the size of the berries. The borders should therefore be made rich; but they ought to be rather wide than deep, deep planting being adverse to the ripening of the fruit. (2.) In order to secure a proper degree of vigour, vines should be limited in extent, and pruned rather severely than otherwise. To enable us to circumscribe the plants, it would be well to introduce as many separate plants into the vinery as can be done without confusion. (3.) From the peculiar mode of growth in the grape-vine, the bearing branches have a tendency to recede from the centre to the extremities, and are often found in abundance only at the top of the trellis. Every young shoot near the front of the house should therefore be carefully husbanded, and cut back by way of reserve. Old wood ought to be removed as frequently as possible; and the skilful pruner will look at least two years before him. Nothing contributes more to regularity in the succession of bearing wood than simplicity in pruning and training; and therefore, all bending, and twisting, and traversing of branches should be avoided.

The summer pruning consists in removing with the fingers the useless lateral shoots, and pinching off the tender points of the bearing branches. The extent to which these bearing branches are allowed to run will depend on their vigour, and the position which they hold in the plant. Sometimes it may be needful to leave them ten or twelve feet long, but, in general, two or three feet will be sufficient. The shorter the better. They seldom or never fail to send out secondary laterals from their points: these and the others which succeed them are stopped at the second or even first eye, and the operation is continued until vegetation ceases. When the fruit is set, all superfluous branches should be cut off, leaving only the best, and the number of these ought to be in proportion to the strength of the vine. When the young grapes begin to swell, the bunches are thinned out, that is, berries are removed wherever they are too much crowded together; and the shoulders or sides of the bunches are supported by slender threads of bass-mat. The quality and weight of bunches should be regarded rather than their number. Nothing seems more contemptible than numbers of small and ill-ripened bunches of grapes, smeared, as they frequently are, with dust and honey-dew. Avarice not unfrequently cheats itself in this matter; and it generally happens in the vinery, as elsewhere, that not he who desires most has most. The ripening, colour, and flavour of grapes on the tree are promoted by free ventilation; this is to be done, however, only after the fruit has attained full size and is beginning to colour.

The forcing of the earliest vinery may commence in January. At first the temperature may vary from 50° to 55° Fahrenheit in the mornings and evenings. When the buds have burst, it may be raised to 70°, and in the flowering season it may be kept at 75°. At this season it is necessary that the air should be preserved moist by frequent syringings. Upon the appearance of colour in the fruit, the waterings cease, and air is copiously admitted. In the early vineries, it is necessary to continue the fire-heat without intermission; in the later houses this is not required, but it must be used occasionally, even in warm weather, to obviate the effects of damp.

The PEACH-HOUSE.—A peach-house, of the *lean-to* form, like the vinery of the same configuration, intended to be commanded by one furnace, is generally about forty feet long, ten or twelve feet wide, and fourteen feet high: but these dimensions may be varied considerably, according to the time at which the crop is desired to come into season. For early forcing, perhaps twenty-five or thirty feet in length, and seven or eight in breadth, are sufficient; while a house, in which the operations of nature are only to be slightly accelerated, may be extended to fifty feet. The span, and ridge and furrow-roofed houses are equally adapted for peaches as for vines, as in such the trees can be treated as standards, which is their natural habit; and in them the fruit is placed in a better position as regards light and air, than in any form of training that can be employed. Fig. 32 is an example of this form. As in the vinery, the front wall is piered to permit the egress of the roots. A common form of a peach-house is represented, of which fig. 33 is a vertical section; *a*, *a*, are the flues or hot-water pipes, placed side by side, *b* is the table trellis, *c* the trellis on the back wall; along with which, a hanging trellis, as in

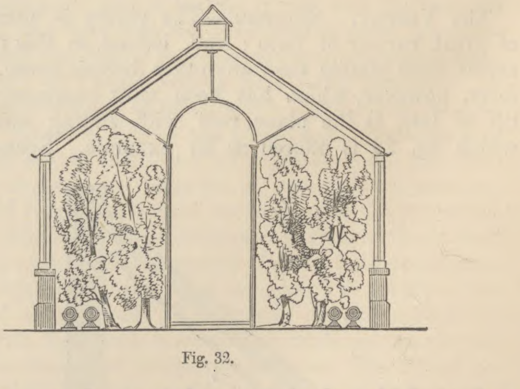

Fig. 32.

Forcing Garden.

fig. 31, is sometimes employed, although this is not approved of by many. The flues or hot-water pipes, which are built on pillars, occupy the centre of the house. The trees are trained to the two trellises *b* and *c*, and to the hanging trellis, if such be in use. Against the back wall three or four dwarf trees are planted, with intermediate *riders*, the latter being taken out at the end of four or five years at farthest. These, with three for the front trellis, make in all nine or ten trees for each house.

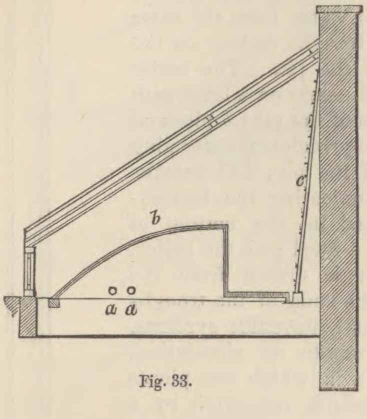

Fig. 33.

Fig. 29, used as a vinery, represents another form of the peach-house, not so generally used as the former, but of equal if not superior merit. We have shewn it heated by a water apparatus, *a, a*. There is no front glass, nor any trellis on the back wall, the trees being planted in front, and trained on a wire trellis *b*, attached to the roof, and covering the whole surface of it. As the peach-tree is not found to extend much more than twelve or thirteen feet on the open wall, the length of the roof, inside measure, need not do more than approach to fourteen feet. But span-roofed houses may be much broader, consequently the length of the sloping roof will be greater, especially as the trees are to be grown as standards.

The pruning and training of peach-trees in the peach-house does not differ materially from the practice out of doors. Fire-heat is commonly applied about the beginning or middle of February; but where there is a large suite of houses, and an extended succession is wanted, forcing, as it then truly becomes, may begin a month sooner. At first the temperature is kept about 45°, but it is afterwards gradually increased to 50° or 55° Fahrenheit. While the trees are in flower, and till the fruit be set, the house is occasionally steamed by sprinkling water on the warm pipes, but much better, in order to secure a more genial evaporation by placing shallow troughs of water so as partly to surround the lower or returning pipe, the lower pipes being less heated than the upper ones. After this period, the foliage is washed, from time to time, with the garden-engine. When the fruit has stoned, or the kernels have been formed, the temperature is raised to about 60°. Water is now copiously supplied to the border; the fruit is thinned out; the various operations of disbudding and tying are performed, and air is admitted in abundance. After the end of April, little fire-heat is required for the peach-house. The trees often suffer from mildew: the best preventives consist in keeping the borders of the peach-house clear, and sufficiently moist, dry air being greatly promotive of that malady, and in observing that nothing be permitted to obstruct the free circulation of air and full admission of sun.

Forcing Garden.

TROPICAL FRUIT-HOUSES.—Several uncommon kinds of exotic fruits are occasionally grown with success in this country. They should, however, be grown in a house, or houses, by themselves. Such now exist, and are denominated Tropical Fruit-houses. Among tropical fruit may be mentioned the Loquat, *Eriobotrya japonica;* the Jamrosade *Eugenia Jambos;* the Purple Granadilla, *Passiflora edulis;* the Granadilla vine, *P. quadrangularis;* the May-apple, *P. incarnata*; the Water-lemon, *P. laurifolia;* and the Sweet Calabash, *P. maliformis;* the Papaya, *Carica Papaya;* and the Banana, *Musa sapientum.* The Leechee, *Euphoria Litchi;* the Long-yan, *Euphoria Longana;* the Mango, *Mangifera indica*, the China Guava, *Psidium Cattleianum*, and the Carambola, *Averrhoa Carambola*, of the East Indies. These have all ripened in great perfection in the tropical fruit-houses of the Duke of Northumberland at Sion House, and several others have ripened in various other establishments in Britain. Indeed, tropical fruit culture has now assumed an important place in British horticulture.

The FIG-HOUSE scarcely differs in form and management from the Cherry-house, the trees being trained to a back trellis, with the addition, however, of dwarf standard trees in front. Figs are very successfully cultivated in the forcing-houses of the Royal establishment at Frogmore, near Windsor. This delicious fruit is, however, less popular in Britain than most others, and is therefore not found in all gardens. The fig succeeds very well as a dwarf standard in the front of a vinery, provided the roof be not too closely covered with the foliage of the vines. Of late, small standard figs have very commonly been grown in large pots, fourteen or fifteen inches in diameter, and placed in any of the forcing-houses. In this way considerable crops of fruit have been raised. The *Figue blanche* and the *Marseilles* are amongst the sorts best adapted for forcing.

The ORANGE TRIBE (*Citrus*) are cultivated in Britain, rather as objects of curiosity and beauty, than for the purpose of affording a supply of fruit. Commerce with Portugal, Spain, Italy, and China, has brought this class of fruits within the reach of every one; and the copious importations which annually take place, have no doubt discouraged the cultivation of the plants. A few orange trees are nevertheless to be met with in most collections, and in large and sumptuous gardens, it is not uncommon to meet with glazed houses set specially apart for their reception.

C. Medica, the Citron, the Cedrate of the Italians, is a small evergreen tree. The fruit is large, of an oval form, and covered with a rough skin or rind, which is charged with a highly flagrant oil. The citron is generally used in confections. It is supposed to be a native of Media, and will not ripen without protection in Britain. Three subvarieties of citron are described by Risso.

C. Limetta, the Sweet Lime. This is rather a tall tree, with diverging branches. The flower is of a fine white colour, composed of five oblong petals. The fruit is globose, with a black nipple-like protuberance at the apex, having a firm rind, and sweet pulp. The colour is pale yellow. It is a native of Asia, but cultivated in Italy. Seven varieties have been described.

C. Limonum, the Lemon. The petioles of the leaves somewhat winged; fruit oblong, with a thin rind adhering closely to the pulp, which is very acid. This, like the preceding, is a native of Asia, but is cultivated in the south of Europe. There are numerous varieties.

C. Aurantium, Sweet Orange. The petioles almost naked; fruit globose, with a thin rind, and sweet pulp. Risso has enumerated nineteen varieties; of which the principal are, the China, the Portugal, and the Maltese.

The CHERRY-HOUSE, in its general arrangements, has

Forcing Garden.

hitherto in general resembled the peach-house, with the exception of the front trellis, the place of which is commonly occupied by a stage for pots of early strawberries or kidney beans. The cherry trees are trained against the back wall; the house should therefore be narrow, and the roof steep. The operation of forcing generally commences early in January, with a very moderate temperature. Air is admitted freely till the flowers begin to expand, when great caution becomes necessary. When the fruit is setting, the temperature is kept as steadily as possible at 50°: after it is set, abundance of water is applied to the roots and foliage of the trees. When the fruit is colouring, water is almost entirely withheld, and air is now freely admitted. During the whole process of forcing cherries, any excessive heat from the sun's rays must be carefully guarded against, by shading or by the admission of air. The kind of cherry usually preferred for forcing is the Common May-duke. A cherry-house ought to form a part of every large garden establishment; for nothing graces the tables of the opulent, in March and April, better than ripe cherries and strawberries in the dessert at that season of the year. The best construction of the Cherry-house is the span-roof, whether the trees be planted permanently in the borders, as they sometimes are, or grown in large pots, which they generally are. In the Cherry-house apricots and plums should also be found, their treatment being almost the same.

The Pine Apple, *Bromelia ananas*, (Linn.) is a native of the new world, although it has been found in such abundance in Africa as to have led some botanists to consider it to be indigenous there also. It reached China from South America, and is now naturalized in most of the West India Islands, to which it was introduced from Peru by Europeans. It appears to have been introduced into Europe about the middle of the 17th century, to England about 1690, and to Scotland by James Justice of Crichton prior to 1744, as he gives plans of his own pine stoves in his British Gardener's Directory, published in that year.

The pine is propagated rarely by seed, frequently by crowns which grow on the top of the fruit, but more generally by suckers which rise from the stem.

Select list of Pines. Black Antigua, Enville, Globe, Russian Globe, Old Jamaica, New Jamaica, Montserrat, Queen, Antigua Queen, Moscow Queen, Ripley's Queen, Smooth Cayenne, Prickly Cayenne, Prince Albert, Providence.

Its propagation and culture have long been carried on in three separate structures, each capable of affording the necessary bottom and atmospheric heat congenial to it. These are denominated the nursing-pit, succession-pit, and fruiting-stove. Many excellent cultivators carry on its various stages of growth in one and the same structure. We shall, howevever, yield to common custom, and speak of them separately.

The *nursing-pit* has occasionally assumed a great variety of forms, respecting which, however, it is not necessary to go into minute detail. For summer use, the Alderston Melon-pit, and Atkinson's Melon-pit, described under the head Melonry, are very suitable. In winter, it is desirable to have the assistance of fire-heat from hot water.

Forcing Garden.

The *succession-pit* performs the same functions as the nursing-pit, but at a more advanced stage of the growth of the plant, and consequently, requires an increase of size. With this difference, Atkinson's Melon-pit does very well for summer use. In colder seasons, we should prefer a pit similar to that represented, figs. 34, 35, in which a hot-water apparatus on the siphon principle is employed to heat the atmosphere of the pits, and the bottom-heat is communicated by the circulation of hot water from the same boiler, in troughs resting on the bottom of the pit. The boiler *a* is placed nearly on a level with the bottom of the pit; *b* pipes on the syphon principle for warming the air of the pit; CC troughs for communicating the bottom-heat, placed in the bottom of the pit on a level with the boiler. The water is drawn from the boiler to the ends of the troughs *d d* by small moveable syphons, which promote its circulation. The bed *e*, in which the plants are plunged, is supported by a flooring of slate, resting on brick piers between the troughs. A boiler placed in the centre is sufficient for a range of sixty feet. Another form of a succession-pit is exhibited in fig. 36, entirely heated by hot water. The surface-heat is supplied by pipes in front; the bottom-heat is kept up by small pipes from the boiler, passing through cisterns of water extending the whole length of the pit. In this case it would be necessary to apply the top heat only during the day.

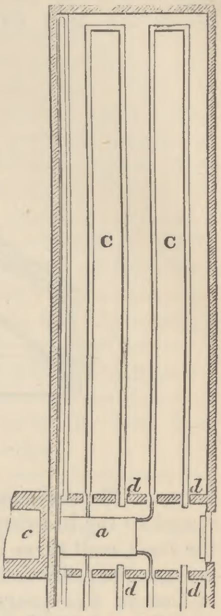

Fig. 34—Ground Plan.

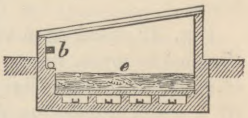

Fig. 35—Section.

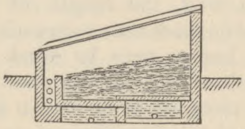

Fig. 36.

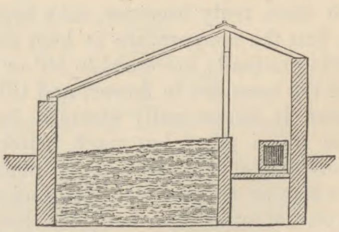

Fig. 37.

In the *fruiting-house*, more room, greater height, and a more powerful temperature, are requisite; and to attain these objects, many varieties of structure have been devised: we shall notice those only which are most worthy of attention. Fig. 37 is a section of Baldwin's Fruiting-pit. The roof is unequally ridged, the north or shorter side being slated and furnished with ventilators, to admit air. With the exception of the slated part of the roof, and the absence of hot-water for bottom and top heat, both of which are great defects, these differ little from the excellent pits of Mr Fleming at Trentham. They have, however, the advantage of being low-roofed, and easily wrought. The sashes are immovable, and the laps of the panes are closely puttied. There is a path within, and a single turn of a flue behind. We should prefer the form exhibited by fig. 38, in which there are also ventilators *a a*, and a hot-water apparatus surrounding the whole pit. The dimensions of this may be fifty feet long, and nine feet wide; the glass being two feet and a half from the curb of the bark-pit in front, and five feet behind. Fig. 39 is a section of a pine-pit with a curvilinear roof, in which the astragals are parallel. A segment of an elliptical arch somewhat less than a quadrant, the origin of the curve being on the front wall, seems better adapted for a pit than any portion of a circle. This pit is supposed to be heated by a small steam-pipe passing through a large iron tank or cistern *a*, filled with water. A section of the old-fashioned pine-stove is given in fig. 40. This was a lofty structure, in the vinery form, with front sashes. It used to be forty or fifty feet long, and twelve or fourteen feet broad, and was commanded by two flues. The flues ought to be exchanged for hot-water pipes, those at the back being placed under the passage, with sufficient cast-iron moveable ventilators let into the pavement for the upward escape of the heat. Or the whole passage ought to be covered with an open cast-iron grating to allow the heat to ascend. In addition to the pine plants in the pit, the roof was also partly covered with vines, a practice justly condemned by Nicol. We are also disposed to agree with that experienced writer regarding the disuse of the pine-stove itself. Besides other grievous faults, a single house affords too little room; and it is a matter of experience, that where the stock of pine plants is not extensive, certain and abundant crops of fruit cannot be expected. Instead, therefore, of a succession and fruiting-house of the old form, with two fires each, involving an enormous waste of fuel, it would be better to have four pits, all of which could be wrought by one fire and boiler. There might be two succession-pits of the form of fig. 34 or fig. 36, and two fruiting-pits similar to fig. 38 or fig. 39. These would contain a much greater number of plants than two pine-stoves, would be much less expensive in erection, and, as the number of fires would be reduced to one, would not consume so much fuel.

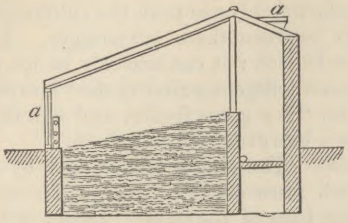

Fig. 38.

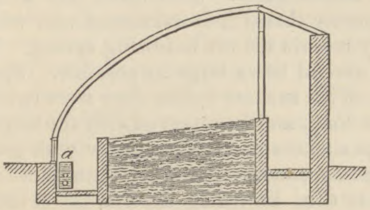

Fig. 39.

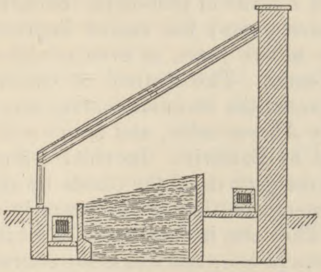

Fig. 40.

The pine being a plant which grows naturally under a tropical sun, it requires all the light our murky climate affords. It is, therefore, better to build the pits of a much greater width than those shewn in our illustrations, for the greater the distance between the side-walls, the more will be the light which obtains access to the plants. A pit, therefore, on the span-roofed principle, 35 feet long, 17 feet wide, and 8 feet from the floor of the passage to the ridge, would be an improvement upon those mentioned. Such a pit could be supplied with both bottom and atmospheric heat from one boiler, the former by placing hot-water pipes within a shallow tank of water placed under the beds, and the latter by carrying a flow and return pipe along the whole length of the sides. Still further to economise fuel, a smoke flue should be placed under the passage, so as to get the benefit of such heat as is not taken up by the water in the boiler, and which usually escapes at the chimney top.

The pine is to be cultivated in its highest state of perfection only when grown in low pits, just sufficient for the full development of the foliage and crown of the fruit. So closely is this adhered to by Mr Fleming of Trentham, one of our most successful cultivators, that he has had occasion to take out a pane of glass to allow the crown of the fruit to protrude into the open air. A passage along the centre of such pits is exceedingly useful, particularly in the fruiting department.

Bottom-Heat. As a substitute for the warmth absorbed by the earth from the powerful rays of the sun in tropical countries, the pots of pine-plants are generally plunged in a bed of tanners' bark, decaying leaves, or other fermenting substances. Tanners' bark is most commonly used.

We have elsewhere stated that no vegetable matter undergoing fermentation can be so economically applied as hot water circulating in properly constructed vaults immediately under the bed in which the plants are set. That the heat may reach by conduction to the roots near the top of the soil in the pots, it becomes necessary that they be plunged in heat-conducting media. When plunged in fermenting material, young pine plants may no doubt be successfully enough grown during summer, nay, even during winter. The question, however, is, does the saving of fuel and the interest on the outlay for the apparatus at all balance the expense of labour and material, the waste of valuable manures, to say nothing of the litter occasioned, and the accidents to which the plants are liable from having their roots burnt or their leaves frozen during winter.

The proper management of bottom-heat is a matter of some difficulty, and in this there have been more failures than in any other part of the pine-apple culture. The heat arising from violent fermentation is greater than the tender roots can bear, and if great watchfulness be not employed, the labour of many months may be blasted in a single day. Bottom-heat is almost universally kept too high. Perhaps the upper limit of its temperature may be fixed at blood-heat, or at most 100°, while the under or winter limit may be brought down to 70° or 75°. The principle of the application of bottom-heat has, until lately, been little understood. In practice, its value has been acknowledged for ages, having been an element in Roman gardening in the days of Claudius. The roots of fruit-trees, even of the hardiest description, become paralyzed whenever they descend too deep into the soil, and this paralysis is one of the evils of deep planting. The summer temperature of our ordinary garden soils is 61° at 6 inches under the surface, 57° at

18 inches, and 44° at 36 inches, but these temperatures are very much diminished if the land is wet or undrained. The roots of trees, therefore, when placed within 6 inches of the surface, or at 61° of temperature, as shewn above, are very differently circumstanced from those which are buried 3 feet, and in a temperature of 44°, when the mean temperature of the air is about 63°. In the former case, there is only 2° of difference, while in the latter there is 19° between the temperature of the air at the roots and that of the air around the leaves, a most serious difference, yet one of frequent occurrence. Hence the necessity of surface-planting and shallow borders, if such borders are not artificially heated below.

The advantage of having the temperature at the roots higher than that in which the leaves are placed, is easily accounted for. Warmth acts as a stimulus to the vital forces, and its operation is in proportion to its amount, within certain limits. If, therefore, the branches and leaves of a plant are stimulated by warmth to a greater degree than the roots, they will consume the sap of the stem faster than the roots can renew it; and therefore nature takes care to provide against this, by giving to the roots a medium permanently more stimulating, that is, warmer, than to the branches and leaves." In all countries where the temperature of the soil is highest, vegetation is strongest, and *vice versa.* Bottom-heat must, however, be regulated, particularly in our forcing-houses, with great care to prevent excess or defect. In its application, bottom-heat must be regulated by the amount of light and of temperature in the air; and hence, so far as practicable, it should be less during the night than during the day, and also less during winter, when we have a deficiency of light, than during summer.

Bottom-heat must also be regulated by the season of the plants; during their winter or season of rest it should be comparatively low—during their summer or season of active growth, it should be considerable; and during their ripening season, it should be highest of all. The necessity of studying these three points may be shewn from the condition of the roots of vines in a cold damp border during the season of forcing, when there is often a thermal difference of 20° between the roots and leaves. This is forcing in the true acceptation of the term. It causes the grapes and peaches to set badly, or not at all, it causes stem or aërial roots to appear on the vines, it causes shanking in the fruit, and the exhaustion and ultimate death of the plants. The malformation in the fruit of the pine, and its starting into fruit at too early a stage of its growth, are also owing to a want of proper unison between the bottom and top temperatures. It is the want of warmth in the soil, fully more than in the atmosphere, that prevents the fine American apples and Flemish pears from ripening so well with us as in other countries, where the winters are much colder than ours, but the summers and soil are much warmer.

Soil. Various nice and minute directions have been given respecting composts for pine plants. Any compost, however, will be found suitable, which is at once rich, fresh, and simple. A mixture of the top-spit, including the turf of an old pasture, and about a half of good, well-rotted dung, combines these qualities as completely as possible. When it is necessary to lighten these materials, a compost of decayed leaves, and a little sand, may be added. It is of importance that the compost, whatever it may be, should be prepared a considerable time beforehand, and frequently turned over. It should be broken with the spade, but not screened; and when used, it should not be too moist. Pine-apple plants are found to shew fruit more readily in a rich light soil, than in strong loam, but do not produce large fruit. In selecting his compost, the cultivator must make his selection between these advantages. At all events the soil must be rich; it can scarcely be too rich. "The pine," says an intelligent writer in the "Gardener's Magazine," vol. ix. "is a gross feeder, and will thrive in vegetable manure, however rich and fresh."

Propagation. The pine is propagated by planting the crowns which grow on the fruit, or the suckers which appear at the base of the stem. These, when removed from the fruit or the stem, are laid aside for a few days, till the scar at the place of separation has dried or healed, as a precaution to prevent their rotting; after which they are potted immediately. Sometimes late in the season, they are merely thrust into exhausted tan, without pots, where they remain till the following spring. In general the offsets should be as large as possible. Speechly did not break off his suckers before they were twelve or fourteen inches long, and he reserved only the largest crowns. These large suckers and crowns grow with greater rapidity, and come sooner into fruit than those of smaller size: and in this, in truth, consists the principal secret of what has been called the short method of culture, by which fruit is obtained in a much briefer space of time than usual. The soil employed in propagation is rather lighter than that afterwards applied. The pots may be from three to six inches in diameter, and, to promote draining, should contain at bottom a layer of shivers or clean gravel. For some time the plants are shaded from the rays of the sun, and in about eight or ten days they receive a little water. As already stated, the older and more common routine of pine-apple culture embraces a period of three years; but recent improvements have reduced these to two years, or even to eighteen months.

Biennial Course. The method of culture which we have denominated the biennial course, was first brought into notice by Abercrombie, and afterwards strenuously recommended by Baldwin. Its chief feature is the acceleration of the growth of the plants by the application of higher temperatures than it was formerly supposed they could bear. They are, in fact, made to attain the growth of two summers in one; and this is the course followed by the best cultivators of the present day.

About the beginning of March, the most forward of the plants potted over winter, or the suckers kept in tan, are taken out, and the earth or tan is shaken away. They are then put into pots about five inches in diameter, which are plunged into frames or pits heated with tan or leaves. They are shaded as usual, and after they begin to grow, receive moderate waterings. When the roots appear around the balls of soil, which will be about the middle of June, the plants are again shifted into larger pots, from six to seven inches in diameter, and, if the heat be declining, are removed into other pits or beds. In the beginning of August they are transferred into larger pots, in which, unless they are intended for early spring forcing, they stand during the winter; and in February they are finally shifted into pots twelve or fourteen inches in diameter. For spring forcing, the last shifting takes place in October, and the pots may be two inches narrower. At every shifting the ball of earth is preserved entire. From March the temperature is gradually increased; air is admitted, and a lively bottom-heat is kept up. When there is danger of burning the roots, the pots are partially drawn up, or even set upon the surface of the bed. The following table will give an idea of the temperature (Fahrenheit's thermometer) and its progressive increase:—

	During Night.	During Day.
March	60° to 70°	70° to 80°
April	70 — 75	80 — 85
May	75 — 80	90 — 100
June	80 — 85	100 — 120

After the beginning of August, the heat is allowed to decline by degrees, until it arrives at the winter temperature of 60°. Where fire-heat is used, and it should always be through the medium of hot water, the nocturnal temperature should only approach towards 80°; and there should be some expedient for the *slow* admission of steam into the atmosphere of the pit. During the whole summer, care is taken to prevent the plants from being *drawn*, and for this purpose they are allowed much space, and are placed as near the glass as possible. In August and September abundance of air, and more copious supplies of water, are given. In winter the chief care is to preserve the roots from damping off, and for this reason, winter pits should have the command of fire-heat.

This mode of *driving*, as it has been significantly called, is by some thought applicable only to the varieties called the Queen. Most of our best cultivators, however, adopt this course, and the fruit produced is larger than that formerly grown upon the triennial course. Those who wish to cultivate such large and coarse sorts as the Providence, may, to a certain extent, adopt the triennial course, either as to time, or to a limited number of plants. This plan will necessitate the following additional routine.

Fruiting-House.—About the beginning of August, the plants, now two years old, are shifted for the last time. The pots are from twelve to fourteen inches in diameter, and the balls are preserved entire. They are then plunged into the bed, and the plants are so treated as to keep them in a growing state during the whole of autumn. In winter, the nocturnal temperature is kept at 60°; but towards the end of January it is gradually raised to 70°. This rise, however, should follow, and not precede or be a cause of, the vernal growth of the plants. About the middle of February, the second fruiting-house may be prepared for the reception of the plants in the biennial succession pit. These are existing in a mild temperature, and start during the general progress of the season.

That period at which pine-apple plants first shew their fruit-stalks, or, as it is technically termed, *start*, is the most critical in their whole culture. It is generally desirable that this should happen at a certain age, and at a particular season; but these are circumstances over which the cultivator can scarcely be said to have a direct control, and accordingly, while the most successful can hardly deem themselves beyond the reach of failure, the less skilful are almost sure to err. We are not aware that the *rationale* of starting has been investigated on the principles of vegetable physiology; and it is certain that the most absurd practices have been resorted to, in order to force the plants into fruit. We pretend not to give a theory; but a few practical remarks may be of advantage. It is evident that the plant must be of a certain age, or at least of a certain magnitude, before it will start freely or to good purpose. Suckers of the first year are wholly taken up with the production of roots and foliage; and if any of them happen to start, they exhibit little more than a tuft of leaves where the fruit should be. In the second year a Queen pine is capable of producing a perfect fruit; and in the third year the New Providence and other large varieties arrive at puberty. The solid part of the stem is then observed to have increased in bulk, and to have ascended considerably above the soil. It is of more practical importance, however, to remark, that the fruit-stalks do not appear until the pot is filled with roots. Apparent exceptions there may be to this principle, but in every case where it does not hold good the plant will be found to be diseased, or the roots to have been violently destroyed. The grower should therefore take care that the roots shall have nearly occupied all the new soil before the end of autumn, and that in the course of the winter the tender fibres be neither exsiccated by drought, nor rotted by excessive moisture. Again, it is probable that at starting there is a peculiar check in the growth of the plant, which causes it to divert the sap from the formation of leaves, and, like most other vegetables in straitened circumstances, to provide the means of reproduction, by throwing out flower-buds. This diversion of the sap is influenced by the quantity of vigorous fibres, for it is observed that when, from some accident, plants not well furnished in this respect, do shew fruit, they bestow the greater part of the sap upon the leaves. Lastly, it is probable that the proper check consists in a transition from growth, however slight, to a temporary suspension of vegetation, which again is followed by a copious flow of the sap, circumstances which, as might be easily shewn, occur both in the winter and summer starting. If these observations be correct, it follows that starting is a natural process, requiring certain conditions in the state of the plant, and therefore not to be forced by violent treatment, or any sudden changes in temperature and watering.

After the plants have shewn fruit, they are never shifted; but the surface soil may be removed, and replaced by a little fresh and rich compost. Water is supplied from time to time as necessity requires; but it is impossible to give any definite rule on this subject. The observant gardener will soon, from experience, discover the proper measure. Water should never be given in a colder state than the average temperature of the house; when, therefore, there is no tank within the house, the watering-pots should be filled, and left in the house for some time before the water be applied. Fire-heat is kept up either continuously or at intervals, during the greater part of the season. It should always be moderate, never exceeding, by itself, 70°. During sunshine, the temperature may range from 70° to 100°. The greater proportion there is of the latter the better. Whilst the fruit is swelling, care must be taken to carry on the growth of the plant with equability and moderation. Violent checks are pernicious; they debilitate the stalk, and cause a stringiness and deformity in the fruit. As the fruit approaches maturity, water is gradually withheld, lest the flavour should be injured. Pine-apples should be cut a short time before they obtain complete maturity. The larger varieties will keep only a day or two; the smaller varieties a week or more.

The Melonry—a department deriving its name from the melon, the principal plant cultivated in it—is an important appendage of the forcing garden. After noticing some of the most necessary apparatus employed in it, we shall treat of the melon, cucumber, &c., and their culture respectively.

The *common hotbed frame* is most usually employed in the absence of more complete structures, and is so well known as to require no description.

The Alderston Melon Pit, of which fig. 41 is a section, is partly above and partly below ground. The front and back walls *a*, *a*, are of brick, supported on piers or stone pillars: *b*, *b*, are spaces enclosed within outer walls, and covered with boards to contain linings, which communicate, without any object intervening, with the fermenting substances in the interior of the pit. These spaces may be two feet wide: the interior pit should seldom be more than six feet in breadth. A principal quality of this structure is its neatness and cleanliness.

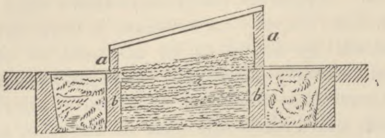

Fig. 41.

West's Melon and Cucumber Pit is also built of brick. It has (fig. 42) a chamber *a* to contain dung; *b* a square opening by which the dung is introduced; *c* rafters of wood or cast-iron, sustaining the interior soil; *d, d,* openings to permit the ascent of steam. The walls are nine inches thick, and the pit may be seven feet wide, inside measure.

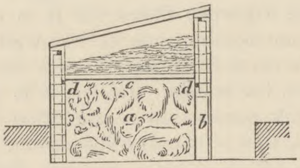

Fig. 42.

Atkinson's Melon Pit (fig. 43) is a brick structure. The back wall *a* and the end walls are four inches thick, built in the pigeon-hole fashion, that is, with square interstices between the bricks. The front wall *b* is double; the interior portion is brick in bed, the exterior brick on edge, with piers under each rafter. The included space communicates with the inside of the bed *c*. The pit *d* is filled with fermenting litter or tanners' bark: *e, e,* are spaces for linings. The whole is sometimes formed of wood, or sometimes only the part above ground.

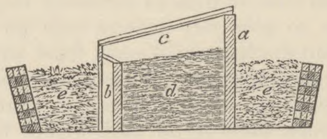

Fig. 43.

The extent of the melonry must depend upon the size of the garden, and the amount of the demand. Where there is a large family, and especially where pine-apples are cultivated (to the forwarding of which some portion of the melonry may frequently be auxiliary), sixty or seventy sashes may be considered as a moderate complement.

Until within a few years, both the melon and cucumber were grown on beds of fermenting material, or in such pits as have just been described. As a matter of course, the fruit in both cases lay on the damp soil in which the plants were grown; in general only separated from it by having a piece of slate or glass placed below them. That neither of these fruits could be brought to their fullest state of perfection in such circumstances will be apparent, when it is considered that they were grown in a high moist temperature, largely charged with ammoniacal and other gases evolving from the vegetable substances employed to produce heat. The underside of the fruit in both cases being deprived of light and air never assumes its natural colour, and the whole fruit often becomes flattened and deformed by its own weight.

The improvements of the present day have provided for these defects by the erection of both Cucumber and Melon-houses, and th employment of large pits, heated by hot water, the plants being trained to trellises under the roof, and the fruit thus allowed to hang suspended in a pure wholesome atmosphere, and exposed on all sides to the influence of the sun and air. These structures are chiefly of the span-roofed form, and are, except in size, exactly similar to span-roofed vineries.

In such structures, cucumbers can be grown during winter with a success unknown in former times, and as the melon is not worth growing during that season on account of the absence of solar influence to ripen it, the Melon-house may be used for forcing kidney-beans or strawberries during the winter months.

The Melon (*Cucumis Melo*) has long been cultivated in Britain, but the period of its introduction and its native country are not well ascertained. The plant is a tender annual, requiring considerable care and skill to rear it in perfection; but it repays the labours of the horticulturist by affording a large, and to most persons a highly palatable fruit. The varieties are numerous, and, from their tendency to sport or vary, are rather fugitive in their duration. Many of the old favourites have disappeared, and those at present in vogue will doubtless take the same course, or will at least assume new forms, while they retain their old names. In these circumstances, it is deemed unnecessary to enter into minute description, or to do more than give a list of the sorts at present deserving of cultivation. It may be premised that they all belong to the species usually called the Musk-Melon (*Cucumis Melo*). The Water Melon (*Cucumis Citrullus*) appertains to the same genus, and is seldom reared in this country except as a curiosity.

Select List of Melons.—Beechwood; Broomham-Hall; Trentham Hybrid, green-fleshed; Cuthill's Early Cantaloupe, remarkable for its hardiness and earliness; Green-fleshed Masulipatam; Green-fleshed Egyptian; Cassabar; Sweet Melon of Ispahan, and Green Valencia.

It is important that none but such seeds as have been procured from approved genuine specimens of the several sorts should be sown. In general, the fresher or more recent that garden seeds are, the better; but the case is different with the melon. Here it is desirable that the seeds should have been kept in a dry state for some years: it is found that plants produced from recent seeds push too vigorously, sending their shoots to a great length before they shew a single fruit; while those from old seeds are less luxuriant in growth, but more fruitful.

The melon succeeds best in a strong, rich soil. A compost, formed of two-thirds of rotted turf, and one-third of old cow-dung, will be found very suitable. This should be prepared some months before being employed in the melon bed.

It is seldom expedient to sow before the middle or end of January, and sometimes it is soon enough a month later. A seed-bed capable of receiving a frame with a single sash is previously prepared. This bed, composed of fermenting stable litter, should be of considerable thickness, perhaps about five feet. Immediately upon its formation, the frame and sash are placed on it, and they are kept close till the heat begins to rise, when the hot vapour is permitted to escape. Three or four days after the bed has been formed, it is covered over to the depth of three inches with earth prepared beforehand. Rich, light, dry earth, is best adapted for this purpose; and that it may be dry enough, it is proper to use such as may have been protected from rain during winter. A few small flower-pots are filled with the same earth, and kept in the hotbed, that the soil in them may acquire a suitable temperature. The seeds are then sown in the flower-pots, and covered half an inch deep; after which the pots are plunged a little way into the earth of the bed. This bed, of course, answers for rearing the early supply of young cucumber plants, and afterwards Chilies, and seeds of other tropical plants. This method is found now to be less expensive than manufacturing the necessary temperature in legitimate Melon or Cucumber-houses during the process of preparing the plants for planting out where they are to produce their fruit.

When hot vapour rises copiously, fresh air is admitted by raising the sash a little. The frame is covered every evening by sunset with mats, and is again exposed in the morning about nine o'clock, sooner or later according to the state of the weather. A single mat is sufficient at first, as the heat in the bed is generally strong. In two or three days after the seed has been sown, the plants appear, and the glasses are raised a little, to admit fresh air, and permit the escape of vapour. Unless this be done, the plants are apt either to damp off or become yellow and sickly. To guard against the casualties of the season, and the chance of miscarriage, it is proper to make two other sowings at short intervals, so that, if any accident befall the first plants, the others may supply their place. Two or three days after the plants have come up, they are transplanted into other small pots, only two or three being put in each pot. If the earth be very dry, it is now moistened with a little tepid water. The pots are then plunged into the earth, and much care and watchfulness are necessary to prevent the roots from being scorched. When the transplanted seedlings begin to grow, they are watered occasionally in the warmest part of the day. As the heat of the hotbed declines, it is supported by linings, applied from time to time, around its outer surface. The lining should not exceed fifteen or eighteen inches in thickness, and should rise above the level of the bed, upon the sides of the frame.

About a month after the seeds have been sown, the beds are prepared in the Cucumber and Melon-houses for the reception of the young plants. This is done by setting the hot water apparatus to work, and by placing upon the beds a supply of compost to become warmed for the reception of the young plants. By the following day, the compost and atmosphere of the house generally acquire a sufficient warmth, and the bed is ready for the reception of the plants. After the tops of the hillocks of earth have been flattened a little, in the centre of each a hole is made capable of containing one of the balls of earth which is to be turned out of the pots. Some of the pots containing the strongest plants are selected, and the young melon-plants are planted out, with balls entire, into the ridges or hillocks already prepared. After this operation has been performed, they receive a gentle watering. When the roots begin to shew themselves through the surface of the hillocks, a quantity of fresh earth is applied all around them, and from time to time additions are made till the whole surface of the bed is covered nearly as high as the top of the hills.

When the plants have got two or three rough leaves, the top of the stalklet, which now begins to elongate, is trained upwards until it reaches the trellis to which the shoots are to be trained. The top is then pinched off, and lateral shoots are produced, which are trained to the trellis as they advance. These laterals will sometimes shew flowers at the second or third joints; if they do not, they are topped in their turn, and afford laterals, which seldom fail to be fruitful. As these runners advance, they are trained along the trellis, and all weak useless shoots are removed. This should be done frequently, as it is found injurious to cut out a great quantity of shoots and foliage at one time. No plant, as has been shown by Mr Knight (*Hortic. Trans.* vol. i.), is more beholden to its leaves, both as respects health and flavour of fruit, than the melon.

It is seldom proper to leave more than one fruit on each shoot, and in the large kinds perhaps not more than four or five fruit should be left on one plant. During the process of growth, the fruit is, from its suspended position, fully exposed on all sides to the rays of the sun. At this period water is given with moderation, and abundance of air is admitted. The fruit should be gathered before being quite ripe. Its approaching maturity is known by the appearance of a number of cracks near the footstalk, and by the emission of a rich odour. It is cut in the morning, and is kept in a cool place till served up; if this precaution be not attended to, there will be a considerable deficiency of flavour.

The average heat required for the successful growth of melons is about 70° Fahrenheit. In the common hotbed, this is maintained by defending the bed during the night, and by applying linings from time to time. In pits or houses heated by hot water circulation, this is easily effected at any season; and such pits doubtless supersede the hotbed frame altogether.

The CUCUMBER (*Cucumis sativus*), like the melon, is a tender annual, requiring the assistance of artificial heat. It properly belongs to the class of culinary vegetables, being used in salads and pickles, and has long been cultivated in this country. Its culture, however, requires the closest attention of the gardener.

Select List of Cucumbers.—Like the melon, these run into endless varieties, if more than one sort be grown in the same structure. The present leading varieties are:—Victory of Bath, Tiley's Captivation, Tiley's Phenomenon, Victory of England, Cuthill's Black Spine, Lord Kenyon's Favourite, Hunter's Prolific, Sir Colin Campbell, Canrobert, Conqueror of the West, Allen's Victory of Suffolk, Snow's Prize, Duncan's Victory, and Sussex Hero.

The culture of early cucumbers so much resembles that of the melon, that it would be useless repetition to enter into minute details. The cucumber, indeed, is somewhat hardier, and therefore in summer requires less heat; but in every other respect the management of the plants is precisely the same. The first crop of cucumbers is generally sown in the end of December, or the beginning of January; a second in March, and a third in June. In summer, cucumber plants, after they have been fairly established, require scarcely any other attention than to thin them out occasionally, and to supply them with water. Seed for a winter supply is sown in August.

Cucumbers, particularly the prickly sorts, are often raised in the warmer months under hand-glasses. A cavity is made in a border in front of a wall or other warm place, and is filled with hot dung. This dung is covered with earth, and two or three plants are put into it, and sheltered with a hand-glass. They are watered and dressed from time to time; and by this means a sufficient supply of small cucumbers, or *girkens*, is obtained for pickling.

In the southern counties of England, pickling cucumbers are easily raised without any artificial heat, being sown in drills in the open ground. The earth is made fine and level, and shallow circular hollows are formed with the hand, a foot wide, and half an inch deep in the middle. The distance between each hollow is three feet and a half, and the distance between the rows five or six feet. Eight or ten seeds are deposited in each cavity. This is done in the beginning of June. When the plants appear, they are thinned out to three or four, the weakest or least healthy being rejected. They are watered occasionally, according to the state of the weather.

The cucumbers are gathered chiefly from the middle to the end of August. Vast quantities of these open ground girkens are taken to the London market. The village of Sandy, in Bedfordshire, has been known to furnish 10,000 bushels of drilled cucumbers in one week.

Gourds, species or varieties of the species of the genus *Cucurbita*, may be grown like drilled cucumbers, or trained against walls or on pales. Though occasionally used as esculents, they are regarded chiefly as curiosities. The *Succada*, or vegetable marrow, is a very useful sort, and in request for the table, being eaten stewed with sauce or mashed like turnips. It may be raised in an exhausted melon-frame or pit; or it may be sown under a hand-glass, and afterwards transplanted into a good aspect, and trained against a wall or trellis.

The **Mushroom** (*Agaricus campestris*), though not properly an inmate of the Melonry, may appropriately enough, from the nature of its culture, be taken along with the plants grown in this department of the garden. It is a well-known fungus, a general favourite, and esteemed a delicacy during winter and the spring months.

Mushrooms are much grown in England on ridges or prepared beds, in sheds, or covered with litter in the open air. The Russian form of the mushroom-house was introduced into Britain by Mr Isaac Oldacre, and is now in very general use. Its arrangement is simple enough, and may be understood from the following description:—Two tiers of boxes, three in each tier, and supported by a strong frame-work, are constructed round the whole house, with the exception of the spaces occupied by a door and two windows. The boxes may be from two feet and a half to three feet and a half broad, and about a foot deep. The house is supposed to be heated by hot water circulation. In the centre is a narrow pit, by which the house may be worked by means of fermenting litter instead of the hot water, or in which rhubarb stalks, &c. may be forced. The windows are furnished with shutters to regulate the admission of light, and are moveable, to permit the ingress of air.

It was long, and by some is still, considered essential to grow mushrooms in darkness. This view is erroneous, and upon correct principles they are grown in houses with as much light as is found in almost any other forcing-house. Mr. John Hawkin has shewn that the principal requisites for its successful culture are heat, *light*, air, and a humid atmosphere. His manner of making up the beds does not essentially differ from that of Oldacre, except that instead of earthing them over with soil, he covers them with turf, having the green or grassy side uppermost.

Mushrooms are propagated from what is technically called *spawn*, which is a collection of vegetable threads pervading dried dung or other similar substance, having the smell of mushrooms, and is apparently the fungus in its undeveloped state. It may be obtained from old pastures, decayed mushroom beds, or purchased from nurserymen in the form of *bricks* charged with spawn. When once obtained, it may, like leaven, be indefinitely preserved. If not otherwise procured, it may be produced, or in a manner generated, by placing quantities of horse-dung and rich earth in alternate layers, and covering the whole with straw, to exclude the rain and air. Mushroom spawn commonly appears in the heap in about two months after the dung and earth have been laid together. The droppings of stall-fed horses, or of such as have been kept on dry food, are found preferable for this purpose.

The old or *ridge* method of growing mushrooms has been referred to above; and, as it has some conveniences, particularly for those who have not extensive apparatus, it may be proper to give some account of it. The beds are formed of horse-droppings which have been laid out for some time without having fermented, and may be made two or three feet broad, and of any length. A layer of dung about eight or ten inches thick is first deposited, and covered with light dryish earth to the depth of two or three inches; then another layer of dung of the same thickness, covered like the former; and lastly a third layer, with its covering. The whole should grow narrower as it advances in height. When the bed is finished, it is covered with straw to protect it from rain, and from the parching influences of the sun and wind. In ten days the bed will be ready for planting or spawning. Pieces of spawn-bricks are inserted in the sloping sides of the bed, about four or five inches asunder. A layer of fine earth is then placed over the bed, and the whole is covered with a thick coat of straw. When the weather is temperate, mushrooms will appear in about a month after the bed has been made; but at other times, a much longer period may elapse. The principal things to be attended to are to preserve a moderate state of moisture, and a proper degree of warmth; and the treatment at different seasons must vary accordingly.

Of the many other methods of raising mushrooms, Mr Oldacre's, already referrrd to, may deserve to be particularized. In forming the compost, he procures fresh short dung from a stable, or from the path of a horse-mill. To this is added about a fifth part of sheep-droppings, or of the cleanings of a cowhouse, or of a mixture of both. The whole ingredients are thoroughly mixed and incorporated. A stratum of the prepared mixture, about three inches thick, being deposited in the boxes already described, is beat together with a flat wooden mallet. Another layer is added, and beat as before; and this is repeated till the beds are rather more than half a foot thick, and very compact. The boxes are then placed in the Mushroom-house, or any outhouse where a slightly increased temperature can be commanded. A degree of fermentation generally takes place; but if heat be not soon perceptible, another layer must still be added, till sufficient action is excited. When the beds are milk-warm, or between 80° and 90° Fahrenheit, some holes are dibbled in the mass to receive the spawn. The holes are left open for some time; and when the heat is on the decline, but before it be quite gone, a piece of spawn-brick is thrust into each opening, and the holes are closed with a little compost. A week afterwards the boxes are covered with a smooth coating, an inch and a half thick, of rich mould mixed with about a fifth part of horse-droppings. The apartment is now kept as nearly and equably at 55° Fahrenheit as circumstances will allow. When the boxes become dry, a little soft water may be sprinkled over them, but sparingly and with circumspection. The more that free air is admitted the better is the flavour of the mushrooms; but the exclusion of frost is indispensable. If a number of boxes has been prepared at first, a few only at a time may be covered with mould and brought into bearing, the rest being covered and cropped in succession, as mushrooms may be in demand.

Mr Callow, in a tract on the artificial growth of mushrooms, describes a method in which the pits are wrought by means of dung heat. His structure somewhat resembles Aitkinson's Melon-pit, only the roof is covered with thatch, and a suite of air-flues is formed within the interior of the pit, with branches crossing the principal bed which occupies the floor. Linings of fermenting litter are applied to the exterior of the house at the back and front. The atmosphere of the pit, in the earlier stage, is kept at 50° to 65° Fahrenheit, and when the bed is in full bearing, about 70°. The other details of this method, or indeed those of the majority of writers on this subject, scarcely differ from those of Mr Oldacre's.

KITCHEN GARDEN.

In this department those plants are cultivated which, after being subjected to various culinary processes, are used as articles of food. They may be enumerated in the order of their importance, each, for the sake of precision, being accompanied by its botanical name.

Cabbage Tribe.

The *Brassica oleracea*, Lin. is a plant indigenous to our rocky shores; but no one, seeing it waving in its native habitat, could possibly anticipate that it would ever appear in our gardens, disguised as the ponderous drumhead or sugar-loaf cabbage, or on our tables as the delicate cauliflower and broccoli. The cultivated varieties are numerous; but the following are the most important.

Common White Cabbage. The economical uses of this vegetable are well known. Its principal subvarieties are the following:—

Atkin's Matchless, Knight's Early Dwarf, Sutton's Dwarf Comb, Sutton's Imperial, Early Dutch Twist, M'Ewen's, Cattel's Dwarf, Barn's, Shilling's Queen, Enfield Market, King of the Cabbages, Chappel's Colewort, London Market, Sprotsboro, Pomeranian, Large Drumhead, Flattened Drumhead. The names in seed lists are endless.

The Cabbage is propagated from seed, which may be sown in beds four feet wide, and covered over with a thin layer of earth. The proper seasons for this operation are the middle of August, the beginning of March, and midsummer. By observing these times, and employing different sorts, the succession may be kept up through the year. For the early spring crops, the late sown plants are in October transferred from the seed-bed to some open and well manured ground, where they are arranged in rows two feet asunder. The principal supply may be put out in February, affording the larger sorts more width between the rows. The crops sown in spring are planted out in May and June. For subsequent culture, all that is necessary is, to keep the ground clear of weeds, and to draw up the soil about the stems. In some situations watering in summer is beneficial.

The cabbages grown late in autumn and in the beginning of winter are denominated *Coleworts*, from a kindred vegetable no longer cultivated. The object is to have them with open or slightly closed hearts. Two sowings are made, in the middle of June and in July, and the seedlings, when they acquire sufficient strength, are planted out in lines, a foot or fifteen inches asunder, the rows being eight or ten inches apart.

The Red Cabbage, of which the large or Dutch red is the common variety, is much used for pickling. It is sown along with the white varieties in August and in spring, and the culture is in every respect the same.

The Savoy. This variety, like the preceding, forms into a close head, but is distinguished by the wrinkling of its leaves. It is a very useful vegetable during the winter months. The principal subvarieties are:—

The Early Green, Globe, the Yellow, the Winter, Marcellin, Flat Green Curled, Large Green German, Early Ulm, and the Feather-stemmed, of which there are various forms.

The seed is sown in autumn and in the end of spring, and two plantings may take place, in April, and in June or July.

Brussels Sprouts. This vegetable is allied to the foregoing, but does not close or cabbage. From the axillæ of the stem-leaves proceed little rosettes or sprouts, which resemble Savoy cabbages in miniature. The seed should be sown in spring, and the seedlings planted out before midsummer, during showery weather. In October the plants should have additional earth drawn to their roots, to firm them, and save them from being destroyed by frost. The earliest sprouts become fit for use in November, and they continue good, or even improving in quality, till the month of March following. Mr Van Mons of Brussels mentions that by successive sowings the sprouts are there obtained for the greater part of the year. In spring, when the plants have a tendency to run to flower, their growth is checked by lifting them, and replanting them in a slanting direction, in a cool shady situation.

Open Kale. The principal subvarieties are:—

German Greens or Curlies, Scotch Kale or Green Borecole, Purple or Brown Kale, Delaware Greens, Buda Kale, Jerusalem Kale, Woburn Kale, and Couve Tronchuda or Portugal Kale.

Of these the first three are considered the most valuable, and are the sorts chiefly cultivated in this country. The seed is sown at various times from February to May, and the seedlings are planted out in moist weather during summer, in rows two feet asunder. The Buda Kale is sown in May, planted out in September, and being hardy, affords a supply in the following spring.

Turnip-rooted Cabbage, or *Kohl-rübe*. Of this there are two varieties, one swelling above ground, the other in it. There is nothing peculiar in the culture, unless that, in the case of the first mentioned, the earth should not be drawn so high as to cover the globular part of the stem, which is the part used. The seed may be sown in the beginning of June, and the seedlings transplanted in July; they are thus fit for use at the approach of winter.

Cauliflower. This variety is cultivated for the sake of the flower-buds, which form a large dense cluster or head, and afford one of the most delicate products of the kitchen-garden.

The varieties are Early London White, Early Dutch, London Particular, Large Asiatic, Walcheren, Wait's Alma.

The sowing, for the first or spring crop, is made in the latter half of the month of August; and, in the neighbourhood of London, the growers adhere as nearly as possible to the 21st day. A second sowing takes place in February on a slight hotbed, and a third in April or May.

The cauliflower being tender, the young plants require protection in winter. For this purpose they are sometimes pricked out in a warm situation at the foot of a wall with a southern exposure, where, in severe weather, they are also covered with hoops and mats. A better method is to plant them thickly in the ground under a common hotbed frame, and to secure them from cold by coverings, and from damp, by giving air in mild weather. For a very early supply, it is useful to be at the pains of potting a few scores of plants; these are to be kept under glass during winter, and planted out in spring, defended with a hand-glass, and watered when necessary. Sometimes, as in market-gardens, patches of three or four plants are sheltered by hand-glasses throughout the winter in the open border. It is advantageous to prick out the spring-sown plants into some sheltered place, before they are finally transplanted and committed to the open ground in May. The later crop, the transplantation of which may take place at various times, is treated like early cabbages. Cauliflower succeeds best in a rich soil and a warm situation. After planting, all that is necessary is to hoe the ground, and draw up the soil about the roots.

It is found that this vegetable, being induced to form its large and crowded clusters of flower-buds in the autumn, may be kept in perfection over winter. Cauliflowers which have been planted out in July, will be nearly ready for use in October. Towards the end of that month, the most compact and best shaped are selected and lifted carefully with the spade, keeping a ball of earth attached to the roots. Some of the large outside leaves are removed, in order that the plants may occupy less room, and at the same time, any points of leaves that immediately overhang the flower are cut off. Where there are pits unoccupied, the plants may be arranged close together, but without touching. Or they may be placed in the same manner in hotbed frames. In mild dry weather the glass frames are drawn off, but they are kept close in rain; and in severe frost they are thickly covered with mats. In this way cauliflower may be kept in an excellent state for several months.

Broccoli has a close affinity to cauliflower, being, like it, of Italian origin, and differing chiefly in the greater hardiness of its constitution. The subvarieties are numerous, and exceedingly diversified. The following are those which are in most repute at present:—

Purple Cape, Green Cape, Grange's Early, Early Purple, Early White, Cream-coloured, Sulphur-coloured, Spring White, Late Purple, Late Danish, Gillespie's, Ellitson's Gigantic Late White, Wilcove's Late White, Hammond's White Cape, Dilcock's Bride, Knight's Protecting, Chappel's Large Cream, Portsmouth, Russian Dwarf, Stewart's Early White, Addison's, and Penzance.

Of the autumnal sorts there should be two sowings, one in the middle of April, and one in the middle of May. As the plants acquire strength they are shifted into the open ground, where they are placed in lines two feet apart. The Cape varieties are of great excellence, being of a delicious flavour when dressed; but on account of the plants being apt to start into flower, their cultivation has in many places been neglected. With proper management, however, this tendency may be overruled. The first sowing may be made on any border of light soil, scattering the seed very sparingly. In about a month the plants may be transferred directly into a quarter consisting of sandy loam, well enriched with rotten dung. The greater part of the second crop should be planted in pots likewise directly from the seed-bed. These pots are to be sunk in the open ground till the heads be formed; and in the end of November they are to be placed under a glass frame, where very fine broccoli may be produced during the severest weather of winter.

The spring varieties are extremely valuable, as they come at a season when the finer vegetables are scarce. They are sown in the middle of March or the beginning of April, and afford a supply from March to May inclusive of the following year.

To obtain seed of the Brassica tribe, true specimens of the different varieties should be selected, in such a state of advancement as that they will flower as early as possible in spring. They should be planted in a an open situation, and kept as far apart from other kinds of the same tribe as possible. As they are very liable to *cross* or hybridize, it is perhaps better, except in the case of some favourite variety, to procure supplies from a respectable seedsman, from whom they are almost uniformly to be had genuine, the extensive seed-growers being at great pains to prevent intermixture of crops.

Leguminous Plants.

Of the Pea (*Pisum sativum*), there are two principal varieties, the Field or Gray Hog Pea, and the Garden Pea. The latter alone requires our attention here. Its chief subvarieties are:—

Bishop's New Long Pod, Prince Albert, D'Auvergne, Dancer's Monastery, Knight's Dwarf Marrow, Fairbeard's Surprise, Fairbeard's Champion of England, Flack's New Large Victory, Victoria Marrow, Bedman's Imperial, Hair's Dwarf Mammoth, Lyn's Prolific, True Early Frame, Warwick. The last two and Prince Albert are adapted for early crops, and the others for successional supplies. In the Sugar Pea, of which there are two sorts, the tall and dwarf, the inner filmy lining of the pod is absent, and the young legumes are used like kidney-beans.

The first crop of peas is sown about the beginning of November, in front of a south wall; and these, after they have appeared above ground, are defended by spruce fir branches, or other spray, throughout the winter. In January and February other sowings are made, and sometimes the seed is put into flower-pots and boxes, and the young plants afterwards planted out in spring. From the end of February moderate sowings should be made twice a month till the middle of August, thus insuring a supply of successive crops of delicate green peas. For the latest crops, the Early Frame and the Charlton are the best. Peas are in general sown in rows from three to five feet asunder, according to the height which the different sorts are known usually to attain; but it is better to sow them in single lines at from ten to fifty or sixty feet apart, and sow the intermediate spaces with other crops. As they grow up the earth is drawn up to the roots, and the stems are supported with stakes, a practice which, in a well kept garden, is always advisable, although it is said that the early varieties, when recumbent, arrive sooner at maturity.

The early crops come into use in May and June, and by repeated sowings, the supplies are prolonged to November. Peas grown late in autumn are subject to mildew, to obviate which, Mr Knight has proposed the following method. The ground is dug over in the usual way, and the spaces to be occupied by the future rows of peas are well soaked with water. The mould on each side is then collected, so as to form ridges seven or eight inches high, and these ridges are well watered. On these the seed is sown in single rows. If dry weather should at any time set in, water is supplied profusely once a-week, In this way the plants continue green and vigorous, resisting mildew, and not yielding till subdued by frost.

Of the Garden-bean (*Faba vulgaris*), amongst many varieties may be mentioned:—

The Early Mazagan, Early Lisbon, Long Pod, Green Genoa, Windsor, Green Windsor, White-blossomed, New Royal Dwarf Cluster, Marshall's Early Dwarf Prolific, Green China, Dwarf Crimson-seeded.

The Mazagan and Lisbon are sown in November, and are defended during winter in the same manner as early peas, but they are more difficult to preserve. The same sorts should be sown again in January and February. In March the New Royal Dwarf Cluster and Long-pod may be put in the ground for a general crop, and subsequently the Windsor and White-blossomed. The latter is a variety of considerable merit, and when the pods are taken at an early stage, they have little of the peculiar bean flavour, or only enough to render them pleasant. During the growth of the bean crop, all the culture necessary is, that the earth be drawn up about the roots. Topping the plants is usually practised, being found to promote the filling of the pods.

Kidney-bean. Under this general title are included the common kidney-bean (*Phaseolus vulgaris*, Lin.) of many varieties; and also the Scarlet Runner (*P. multi-*

florus, Willd.) Kidney beans are the *haricots* of the French, who enumerate upwards of 200 varieties. The sorts usually cultivated in this country are:—

Early Red Speckled, Early Black, Early White, White Battersea, White Canterbury, Black Speckled, Brown Speckled, Scarlet Runner, Dutch White, Early Dwarf Dutch, Fulmer's Early Dwarf, Wilmot's Forcing Cream-coloured, Black Belgian, Newington Wonder—the last two are the best of the family—Dwarf Negro, Long-podded Negro, Sabre.

The first three, and Fulmer's Early Dwarf, are the earliest; the others are more productive, and better fitted for a general crop. As the plant is of tropical origin, our climate is scarcely sufficient for the extensive cultivation of the ripe beans, which are the principal object in France and Italy. The immature legumes are chiefly used in this country.

It is seldom advantageous to sow kidney-beans in the open ground before the middle or end of April; after which period successive sowings may be made every fourteen days to the end of July. The plants are grown in rows two feet apart, and the earth is carefully drawn to the roots. Kidney-beans are well adapted for forcing, in hotbeds, or in hothouses; the climate of the Peach-house, when it can be obtained, being considered the best. The sowings may begin in January; they are made in pots, and a supply may be thus obtained in the months of March, April, and May. Wilmot's, Fulmer's, and Newington Wonder, are the best for forcing.

Esculent Roots.

The **Potato** (*Solanum tuberosum*). This well-known plant is a native of the elevated regions of equatorial America. It was introduced into Europe about the middle of the 16th century, but remained little known or regarded till within the last hundred years; it is now so generally cultivated, as to have effected almost an economical revolution in this country. Most of the original British sorts were derived from Ireland. Its multitudinous varieties now set enumeration at defiance, and many are indeed appearing and disappearing every year. The descriptive list of Messrs P. Lawson and Son contains 175 sorts. The culture of the late sorts properly belongs to the farm, and when the gardener has to take them under his care, he will find it best to adopt such as are common in the agriculture of the district. Of the early kinds, most of which are supposed to have originated in Lancashire, the following may be esteemed the best:—

Early Royal Dwarf, Early Ash-leaved, Early Frame, Early Kidney, Walnut-leaved Kidney; Tyer's Early and Golden Dwarf are the best fitted for forcing and very early crops; and the Forty-fold, American Early, Lapstone Kidney, Fluke, Alstone Kidney, are the best for general crops; while the Prince Regent, Stafford Hall, and Pink Eyed, continue good till May or June.

Potatoes are commonly propagated by dividing the tubers, leaving to each segment one or two eyes or buds. The sets are then planted by the aid of the dibble or spade, in rows at a distance varying from fifteen inches to two feet. It has been suggested by Mr Knight (*London Hortic. Trans.* vol. vii.), and his views have been amply confirmed by experiment, that by planting whole tubers, and at greater distances, a larger produce will be obtained. Mr Knight proposed to leave four feet between the rows, a distance which, except with the larger varieties, was found to be too great. An experienced horticulturist in Scotland states, that by planting whole tubers, and by leaving in the case of dwarfs two feet, and in the tall varieties two feet and a half, between the rows, a return from one-third to one-half more was obtained than could be had by the old method. Of course a greater quantity of tubers is required for planting, but this bears no proportion to the great increase which results; and besides, early potatoes at the planting season being unfit for eating, there is little economy in sparing them.

The earliest crops should, if possible, be placed in a light soil and in a warm situation, and be planted about the middle of March. Sometimes the eyes of the tubers are made to spring or vegetate on a hotbed, and the plants are put out as soon as the leaves can bear the open air. When the sprouts are about two inches long, they may be planted out towards the end of March. Young potatoes are thus procured in seven or eight weeks. A secondary planting of tubers should be made before the middle of April. When the stems are a few inches above ground, the earth should be drawn to them; an operation, however, which, while it improves the crop, delays its maturity for two or three weeks. Mr Knight recommends removing the flowers as they appear, and states that by this means the produce is increased by a ton per acre. The fine early varieties, however, scarcely produce any flowers.

An important fact in the cultivation of the potato was observed about the year 1806, by Mr Thomas Dickson of Edinburgh, viz., that the most healthy and productive plants were to be obtained by employing as seed-stock unripe tubers, or even by planting only the wet or least-ripened ends of long-shaped potatoes; and he proposed this as a preventive of the well-known disease called the *Curl*. This view has been confirmed by Mr Knight. An intelligent writer in the *Gardener's Magazine* (vol. ii. p. 171) states a method by which sprouting of the eyes is accelerated. He takes up the seed potatoes a considerable time before they are ripe, and exposes them for some weeks to the influence of a scorching sun. The resulting crop is at least a fortnight earlier; but it is not said how this practice affects the curl.

The forcing of early potatoes on hotbeds has long been practised; but it is attended with considerable trouble and expense. Small supplies of young waxy tubers are now often produced during winter, in boxes placed in a Mushroom-house, or in a common cellar, if free from frost. In October, old potatoes are placed in layers, alternating with a mixture of tree leaves and light mould. Vegetation soon proceeds; and there being no opportunity for the unfolding of stems and leaves, the energies of the plants are expended in the production of young tubers. Before midwinter these often attain the size and appearance of early potatoes; but they are much inferior, being watery and of little flavour. Of late years the potato has been so seriously attacked by an epidemic disease, as almost to threaten its total extinction. The cause of this has led to much controversy without any satisfactory result. Potatoes were more healthy in 1855 than they have been in any year since the appearance of the disease, and there is hope that the malignity of the epidemic is passing away.

Jerusalem Artichoke (*Helianthus tuberosus*), or tuberous-rooted sunflower. This plant, which is a native of Brazil, derives its epithet *Jerusalem* from a corruption of the Italian *Girasole*, a sunflower, and *Artichoke* from the resemblance, in flavour, which its tubers bear to the floral receptacles or *bottoms* of the artichoke. It is propagated by means of its tubers in the manner of potatoes. In March they are planted out in rows three or four feet asunder, and in autumn the new tubers are fit for use. For the sake of convenience, it is advantageous to store them, though the roots are hardy enough to bear the winter frosts. Some, indeed, allow them to remain in the ground, and dig them up when required. In this way a sufficient number of sets is generally left in the ground, and the stalks are thinned into rows in summer; but this is a slovenly mode of treatment, and seldom produces well-flavoured crops. To insure large tubers, a rich soil is required, and if of a peaty nature so much the better.

The Turnip (*Brassica Rapa*), like the potato, has, to a great extent, migrated into the fields, and become the care of the husbandman more than of the gardener. The following are the most esteemed garden sorts:—

Early White Dutch, Early Stone, Green-topped White, Long White, Early Yellow Maltese, Dutch Yellow, Aberdeen Yellow, Long Yellow, Robertson's Golden Stone, Yellow Jelly, Finland, Early Six Weeks.

Besides these, the *Navet* of the French (*Brassica Napus* v. *esculenta*) is occasionally cultivated, and more frequently the *Swedish Turnip* (*Brassica campestris* v. *Napo-brassica*, L.), which is a most excellent winter sort, though it belongs more properly to the farm. For early crops, the white Dutch is the principal variety; the other white sorts, and the beautiful yellow Maltese, are useful in summer and in the beginning of autumn. The yellow Dutch, being capable of enduring any degree of frost, affords the best winter supplies.

Turnips succeed best in a rich, well-worked soil, of a light or medium quality. The first sowing is made about the end of March, in a warm situation; and it is usual to put in additional sowings, once a fortnight or three weeks, till the end of August. The early crops are sown *broadcast*, and the later in drills. After the plants have shewn a rough leaf or two, they are thinned out, being left at the distance of eight or ten inches in the drill; and the ground is hoed and kept free from weeds. As turnips which have stood the winter throw up their seed-stalks early in spring, after which their roots become stringy, and are much deteriorated, it is useful to store the turnips in winter, keeping them in a close place, and covering them with straw. Seed from three to four years old is better than that of the preceding season, particularly for the early varieties, the plants from such being less liable to run to seed without forming bulbs. The same holds good in field culture, while the plants run less to leaves and expend their energies in the formation of larger and better formed bulbs.

The young plants, while in the seed-leaf, are often destroyed by a small beetle called the turnip-fly (*Haltica nemorum*). Many remedies have been proposed; it has been found beneficial to dust the rows with quicklime; but perhaps the best precaution is to sow thick, and thus insure a sufficient supply both for the insect and the crop.

The Carrot (*Daucus Carota*) is one of our native Umbelliferæ, but has been much transformed by cultivation. The best varieties are the Early Horn and the Long Horn, the former for early, the latter for general cultivation. The Altringham is also a good garden sort. The carrot loves a light, deep, fresh soil, in which it may be at liberty to push down its long spindle-shaped roots. A few Early Horn carrots may be sown in February on a moderate hotbed. In the beginning of March, the same sort may be sown in the open air. In April, the other sorts may follow as a general crop; it succeeds best in drills. In many old gardens the early plants are liable to the attacks of a small grub, the larva of *Psila rosæ*, or carrot-fly; it is therefore a useful precaution to sow a moderate crop of the Early Horn variety in July. After sowing, it is only necessary to thin the plants and keep them clear of weeds. The roots are stored in winter in the manner of turnips.

The Parsnep (*Pastinaca sativa*) is now less cultivated than it was in Catholic times, when it was a favourite accompaniment to dried fish in Lent. To some its flavour is not agreeable; but it is a very nutritious vegetable, and of easy digestion. Like the carrot, its root is long and tapering, differing chiefly in being of a whitish colour. Its culture is also very much the same. The best sorts are:—

The Long Jersey, Early Short Horn, Turnip-rooted, and Hollow-crowned.

Red Beet (*Beta vulgaris*) is a biennial plant, a native of the shores of the south of Europe. The boiled root is eaten cold, either by itself or as a salad; it is also often used as a pickle. The varieties are numerous, but the best are—

Barrat's New Crimson, Whyte's Black, Glen Dwarf Red, Atkin's Crimson, and New Blood-red or Mulberry.

There is a fine French variety called Castelnaudary, from a town in Languedoc, which is esteemed for its peculiar flavour.

Red beet prospers in a rich, deep soil, not recently manured, and which has been well pulverized by the spade. During April the seeds may be sown in drills, fifteen inches asunder, and the plants are afterwards to be thinned to eight inches from each other in the lines. In the northern parts of the island, the roots are stored in winter, care being taken not to break them or cut off the leaves too closely, as they bleed when injured.

Skirret (*Sium Sisarum*) is a native of China, too seldom seen in our gardens. Its tubers are used like parsneps. It is a perennial, and may be propagated by separating the roots in spring; but it succeeds better by annual sowings, which may be made in April.

Scorzonera (*Scorzonera Hispanica*) and Salsify (*Tragopogon porrifolius*) are generally associated together in gardens, and are now less cultivated than they deserve. The roots are used in soups, and sometimes as dressed side dishes. They are sown in lines, and treated like the crops of red beet or parsnep.

The Radish (*Raphanus sativus*) is a native of China. There are two principal varieties, the spindle-rooted and the turnip-rooted radish; and of these the subvarieties are numerous. The following may be mentioned:—

Early Frame Scarlet, Short-topped Scarlet, Scarlet Salmon, Long White, White Turnip, Yellow Turnip, White Spanish, Black Spanish.

The first two and the white turnip radish are best suited for early crops; the scarlet salmon for summer, the yellow turnip for autumn, and the white and black Spanish for winter.

Some cultivators sow their earliest crop in November, in a warm situation, at the foot of a wall or in front of a pinery, and continue sowing once a-month, if weather permit, during winter. Others grow their first radishes under frames, aiding vegetation by a slight bottom-heat. As the season advances, successional supplies are sown once a fortnight. From the middle of July to the middle of September, the turnip-radishes are sown from time to time; and on the approach of frost they may be stored up in sand like carrots, and kept throughout winter.

Oxalis Roots (*Oxalis crenata*, Jacq.; *O. arracacha*, G. Don) and some other species of the genus, have of late years been cultivated for the table in this country. They are not, however, held in much esteem, and are very rarely cultivated. The same may be said of the recently introduced Dioscoria Japonica.

Alliaceous Plants.

The **Onion** (*Allium Cepa*) is too well known to require description; it has been cultivated in this country from time immemorial. Among the varieties may be enumerated:—

Strasburgh, Deptford, James's Keeping, Silver-skinned, White Portugal, Blood Red, Potato Onion, Brown Globe, New White Globe, Reading, Tripoli, Madeira Large, Lisbon.

Besides these, the Welsh Onion or Ciboule (*Allium fistulosum*, L.), a native of Siberia, is sometimes grown for scallions. For a general crop, the Strasburgh, Deptford, and Globe varieties may be esteemed the best. The White Portugal grows to a large size, but does not keep well. The Silver-skinned is chiefly used for pickling.

The onion affects a light, rich, well-worked soil, which has not been recently manured. The principal crop may be sown in the course of the month of March, according to the state of the weather and the dryness of the ground. Onions are grown in drills, ten inches apart, and are regularly thinned, hoed, and kept free from weeds. About the beginning of September the crop is ripe, which is known by the withering of the leaves; the roots are taken up, and, after being well dried, are stored in a garret or loft, where they may be perfectly secured from damp.

Towards the end of August a secondary crop is sown, to afford a supply of young onions or *scallions*, as they are called, in the spring months. The Strasburgh and White Portugal may be used for this purpose. Those which are not required for the kitchen being allowed to stand, if the flower-bud is picked out on its first appearance, and the earth stirred about them, frequently produce bulbs equal in size and quality to the large ones that are imported from the Continent.

Some horticulturist srecommend the transplanting of onions. Knight sows the White Portugal onion in spring under the shade of a tree, where it remains of a diminutive size. The onions are kept over winter, and are planted out in the succeeding spring. Some cultivators used to collect all the minute bulbs of the ordinary crop, and use them in the same way; while others confined the operation to one summer, and sowed in February on a slight hotbed, or sometimes merely under a glass frame. In the first or second week of April, according to the state of the weather, they are transplanted in rows, eight inches asunder, and at the distance of four or five inches in the row. Previously to planting, the roots of the seedlings are dipped in a puddle of one part of soot to three parts of earth, an expedient which is found to secure the transplanted onions from the grub. Onions thus treated attain a large size. Autumn-sown onions submitted to a similar treatment produce excellent crops.

The **Potato Onion** is propagated by the lateral bulbs, which it throws out, under ground, in considerable numbers. It is planted about mid-winter, and ripens in summer. Its flavour is strong, and not unpleasant; but the plant being rather delicate and troublesome in cultivation, is not likely to supersede the common onion.

The **Pearl Onion** produces clusters of small bulbs at the root. These little bulbs are of a fine white colour, like the silver-skinned onion, and very fit for pickling.

The **Leek** (*Allium Porrum*) is a native of Switzerland, but has probably been cultivated in this island for many centuries. The varieties are:—

The London flag, Musselburgh, Dutch flag, Erfurt, and Rouen. Of these the Musselburgh leek is considered the most hardy.

Leeks are sown in beds in spring; and in June or July are planted out in rows fifteen or eighteen inches apart, and six inches asunder between the rows. When the weather is moist, it is found beneficial merely to lay the plant into the hole made by the dibble, without closing the earth upon it, the stem being by this means encouraged to swell out and fill the hole, as well as being blanched at the same time.

Shallot (*Allium Ascalonicum*) is a native of Palestine. It is much used in cookery for high-flavoured soups and gravies, and is sometimes put into pickles. It is propagated by offsets, which are commonly planted in September or October. Some recommend the mixing of soot with the manure as a protection against maggots, by which this plant is greatly infested. Autumn planting, however, is found the best expedient, as the bulbs are ripe before the larvæ commence their depredations. There are two sorts, the Common, and the Russian which is much larger and less pungent.

Garlic (*Allium sativum*) and **Rocambole** (*Allium Scorodoprasum*), though common ingredients in Continental cookery, are comparatively seldom used in this country. A few rows will generally be found sufficient. They are propagated by offsets from the roots, or by the bulbils which grow on the flower-stem. The **Chive** or *Cive* (*Allium Schœnoprasum*), a pleasant little native plant, is used occasionally as salad and alliaceous seasoning. A single row may be planted as an edging, and it is easily increased by parting the roots in spring and autumn.

Spinaceous Plants.

Spinach (*Spinacia oleracea*) is an annual plant, and is a native of Western Asia. It has long been cultivated for the sake of its succulent leaves, which, when properly dressed, form a pleasant and nutritious article of food. There are three varieties; the round-leaved or smooth-seeded, the angular-leaved or prickly-seeded, and the Flanders. The two latter, as being the most hardy, are used for the winter crop.

The first sowing is made in August, in some sheltered but not shaded situation; the plants, as they advance, are thinned, and the ground is hoed. In the beginning of winter the outer leaves become fit for use; in mild weather, successive gatherings are obtained, and, with proper management, the crop may be prolonged to the beginning of May.

To afford a succession crop, the seeds of the round-leaved variety should be sown in the end of January, and again in February and March. From this period it is proper to sow small quantities once a fortnight, summer spinach lasting only a very short time. The open spaces between the lines of peas will generally afford enough of room for these transient crops. They are generally sown in shallow drills, and are thinned out and weeded as may be required.

White Beet (*Beta Cicla*) is cultivated for the leaves, which are used as spinach. The midribs and stalks of the great white beet, when separated from the leaves, are stewed and eaten as asparagus, under the name of Swiss Chard. The culture does not differ materially from that of the red beet.

Garden Orache (*Atriplex hortensis*), **Wild Spinach** (*Chenopodium Bonus Henricus*), and **Garden Patience**

(*Rumex Patientia*), are sometimes used in place of common spinach; but as, in this country at least, they are deemed rather curious than useful, it may be sufficient to indicate their names. The same may be said of the NEW ZEALAND SPINACH (*Tetragonia expansa*), and QUINOA SPINACH (*Chenopodium Quinoa.*)

Asparaginous Plants.

ASPARAGUS (*Asparagus officinalis*) is a perennial plant, a native of the shores of Britain, where it occurs sparingly, and of the steppes in the east of Europe. Though somewhat unpromising while in a state of nature, it affords, in cultivation, an esculent of considerable value, and is therefore grown extensively both in private and in sale gardens. The principal varieties are the *Red-topped* and the *Green-topped*, of which the latter, while it is less succulent, is considered the better flavoured. There are numerous subvarieties, such as the Battersea, Gravesend, Giant, &c., which differ only slightly or not at all from those already mentioned.

Asparagus, growing naturally on loose sand, loves a light deep soil, through which it may be able to shoot its long stringy roots. Two feet and a half is considered a desirable depth, but in France the ground is sometimes prepared, by sifting to double that depth. A considerable portion of well-rotted dung or of recent sea-weed is laid in the bottom of the trench, which may be from two to three feet deep; and another top-dressing of manure should be digged in preparatory to planting or sowing. The older horticulturists used to grow their asparagus in beds four or five feet wide, with intervening alleys of about eighteen inches in breadth. At present, in Scotland, it is customary to sow or plant in rows from three to four feet asunder; a method which, in every way, is found to be most convenient. Except where the garden is new, when, of course, it is advantageous to procure a supply of ready grown plants, it is thought preferable to keep up the stock of asparagus by sowing.

The sowing is made in March, in slight drills; and, as a portion of the seed often fails to germinate, it is a good precaution to employ nearly a double quantity of seed. If the plants come up too thickly, they may be thinned out towards the end of the first summer, to the distance of about six inches in the rows. The ground is hoed, and kept clear of weeds. It is a common practice to take slight crops of onions, lettuce, cauliflower, or turnip, between the lines of asparagus during the first, and, if the rows be wide, also during the second year. The young heads or stalks, the part used, should not be cut before the third spring, and they are not in perfection till the fourth or fifth.

The asparagus quarter can scarcely be over manured. The proper time to perform this operation is in the end of autumn, when the annual flower stalks are removed, preparatory for winter. When beds are employed, their surface should be stirred with a fork; a layer of well-rotted hotbed dung is then laid on, and the whole covered with a sprinkling of earth from the alleys. If the plants are grown in rows, the manure is simply dug in by means of a three-pronged fork, care being taken not to injure the roots. This operation is repeated annually. No other culture is required; but it is necessary to observe a due moderation in reaping the crop, as the shoots, when much cut, become progressively smaller and less valuable. Hence a considerable quantity of ground is required for the cultivation of this vegetable, and it is a general rule never to gather it after peas have come into season.

Asparagus readily admits of being *forced.* The most common method is to prepare, early in the year, a moderate hotbed of stable litter, and to cover it with a common frame. After the heat of fermentation has somewhat subsided, the surface of the bed is covered with a layer of light earth or exhausted tan-bark, and in this the roots of plants five or six years old are closely placed. The crowns of the roots are then covered with two or three inches of soil. A common three-light frame may hold 500 or 600 plants, and will afford a supply for several weeks. After planting, linings are applied when necessary, and air is occasionally admitted. Care must be taken not to scorch the roots. Where there are pits for the culture of late melons or succession pine plants, such as the Alderston-pit, or the succession-pit with the hot water circulation, they may advantageously be applied to this purpose; but a pit heated in the tank manner is by far the most convenient and certain.

It has been recommended (*Lond. Hortic. Trans.* vol. v.) to force asparagus on the ground on which it grows. This practice is very generally followed on the Continent, but the result is by no means to be compared with that of taking up the roots and treating them as above. A succession of crops must be maintained by annually sowing or planting new beds so as to keep up the supply.

Before leaving this subject, it may be mentioned, that about Bath, the young flower-spikes of *Ornithogalum pyrenaicum*, found native in that neighbourhood, are used like asparagus, under the name of *Prussian grass.*

SEA-KALE (*Crambe maritima*) is a perennial plant, growing spontaneously on the shores of the southern parts of the island. The roots are spreading, the leaves waved, glaucous, and covered with a fine mealy bloom, and the stalks rise to about two feet high, bearing white flowers, which smell of honey, followed by seed-pods, each containing a single seed.

The country people in the west of England have long been accustomed to use in spring the young shoots, which, by passing through the sand and gravel on which they grow, are somewhat blanched and rendered tender. In conformity with this practice, the cultivation formerly recommended consisted merely in covering the beds on the approach of spring with a little dry earth or sand, in order to blanch or intenerate the shoots. These were cut as they appeared in March and April. Now, however, the blanching is not only much more completely effected, but simple means have been devised for supplying the table for half the year, including all the winter months. It has, within these few years, become a vegetable of common occurrence in the markets both of London and Edinburgh.

Sea-kale seems partial to a light dry soil. If manure be added, it should consist of sea-weed or leaves of trees. The plants may be propagated by offsets, or small pieces of the roots having buds or eyes attached to them; but the most eligible method is by seed. We have seen very tolerably blanched stalks produced by plants only nine months old from the seed, and after two summers, seedling plants will have acquired sufficient strength for general cropping. The sowing is made in March, the seeds being deposited in patches of three or four together, the patches being arranged in lines three feet apart, and two feet in the line. In order to secure a succession, and to obviate the bad effects of forcing, it is proper to sow a few lines of sea-kale every year.

With the aid of pots, sea-kale is forced in the open border in the way now to be described. In the latter end of autumn, the plants are dressed, that is, the stalks are cut over, and the decayed leaves are removed. The ground is, at the same time, loosened about the eyes, and a thin stratum of gravel or sifted coal-ashes mixed with salt, is laid on the surface to keep down earth-worms. A pot with a moveable cover is placed over each plant or each patch of plants. Leaves of trees are then closely packed all round the pots, and raised up to about a foot above them; the whole thus assuming the form and appearance of a large hotbed. When fermentation commences, a thermometer should be occasionally introduced into a few of the pots, to ascertain that the temperature within does not exceed 60° Fahrenheit, and the depth of the leaves is to be regulated accordingly. The vegetation of the included plants is speedily promoted; so that, in the space of a month or six weeks, the shoots will be ready for cutting, and, being thus excluded from the light, they are most effectually blanched, and are exceedingly tender and crisp. By means of the moveable lids, the plants are examined and the shoots gathered without materially disturbing the covering. By commencing at various times, a supply for the table can be readily furnished from the middle of November till the middle of May.

The Artichoke (*Cynara Scolymus*) is a perennial plant, a native of the south of Europe, and is a well-known inhabitant of our gardens. It resembles a thistle on a large scale. In France, the entire head or whole leaves of the involucre of the artichoke are eaten, when in a young and tender state, *en poivrade*, or with pepper, salt, and vinegar; but in this country the only parts used are the base of the leaves of the involucre, and the immature floral receptacle, or phoranthium, commonly called the *bottom*, freed from the bristly seed-down which has been called the *choke*. The varieties are the Conical or French, the Globe or Red Artichoke, and the Dwarf Globe. Of these the first is the highest flavoured, the second is well adapted for a general crop, and the third is prolific, and occupies little room.

The artichoke loves a deep cool dry soil. It is propagated by parting the roots in April, the sets being planted in rows four or five feet asunder, and two feet apart in the rows. The young plants generally afford a crop which succeeds that of old plants; and for this reason a new plantation is made in some gardens every year. During summer the plants are kept clear of weeds, but require little other attention. In November the decayed stems and leaves are removed, and the ground cleared. In some gardens the earth is ridged slightly around the roots, in order to defend the stools from the frost. This, however, is done more effectually by a covering of sifted coal ashes or rotten tan, of the depth of a foot, drawn close round the base of the leaves. In April this protection is taken away, the stocks are examined, and two or three only of the strongest shoots are permitted to remain. The offsets, which are carefully removed, afford materials for a young plantation. The ground between the rows is forked over. At this time manure may be applied; well-rotted hotbed dung, and above all seaweed, being considered preferable.

The Cardoon (*Cynara Carduncului*) is a perennial plant, a native of the south of France and Spain. It has a close resemblance to the artichoke, but surpasses it in size. The edible part, or *chard*, as it is called, is composed of the blanched and crisp stalks of the inner leaves. Besides the common sort there is a prickly variety, known in France by the name of the Cardoon of Tours. The common artichoke is also used for the production of chard. Cardoons are found to prosper on light deep soil. The seed is sown annually about the middle of May, in shallow trenches, like those for celery, and the plants are thinned out to ten or twelve inches from each other in the lines. In Scotland it is preferable to sow the seed in small pots, one seed in each, placing them in a mild temperature, and when the plants have attained the height of eight or ten inches, to transplant them into the trenches. In dry weather water is copiously supplied, not only to increase the succulence of the leaves, but to prevent the formation of flower-stalks, which render the plant useless. In autumn the leaves are applied close to each other, and wrapped round with bands of hay or straw, the points of the leaves only being left free. Earth is then drawn up around the leaf-stems to the height of fifteen or eighteen inches. Sometimes cardoons are blanched by a more thorough earthing up, in the manner of celery, but in this case the operation must be carried on from the end of summer. During severe frost the tops of the leaves should be defended with straw or litter.

The Rampion (*Campanula Rapunculus*) is an English native biennial, the roots of which, under the name of *ramps*, are used as a salad, or boiled like asparagus. It is but little cultivated in this country. The seed is sown broadcast about the beginning of June, in a cool situation, and the young plants are merely to be thinned and kept clear of weeds. On the approach of frost, the roots, which somewhat resemble small radishes, are stored in sand, and will keep fresh and firm till spring.

Salads, &c.

Lettuce (*Lactuca sativa*) is a hardy annual, but of what country it is a native is unknown. Some suppose it to be a seminal variety of the native *L. virosa*, a poisonous plant, "which," says Professor Lindley, "would not be more remarkable than the fact, that the indigenous celery is one of our strongest poisons." Besides its well known uses, it may be mentioned that the late Dr. Duncan senior, of Edinburgh, prepared from its milky juice a medicine denominated *Lactucarium*, similar in its action to opium, but capable of being administered in cases where that powerful drug is inadmissible. There are two principal varieties, the Cos or upright, and the Cabbage-lettuce. The subvarieties are numerous; we may mention the following:—

Early Forcing Cos, White Cos, Cilicia, White Cabbage, Brown Dutch Cabbage, Imperial Cabbage, Grand Admiral, Green Paris Cos, Paris White Cos, Brown Cos, Wait's White Cos, Neapolitan Cabbage, Malta Cabbage, Hardy Green Hammersmith, Tennis Ball, Black-seeded Grotte.

By proper care fresh lettuce may be had throughout the whole year. The first sowing is made in January, in some sheltered situation, or under hand-glasses, or in February on a gentle hotbed. The seedlings are transplanted as soon as the weather will permit. A second sowing may be made in the beginning of March, and another in April. Besides the ordinary compartments, the seedlings may be planted on celery ridges, between rows of slight crops of other vegetables, and, in short, in any odd corner which may occur. To obtain a winter supply, a sowing is made in August or September, and the plants are pricked out in October, along the bottom of walls, or under glazed frames.

Endive (*Cichorium Endivia*) is an annual plant, a native of China, from which it was introduced in 1548. It is the lettuce of winter, the blanched hearts being used for salads and in soups.

There are two highly marked varieties, namely, the Batavian or broad-leaved and the Curled, and of these there are many subvarieties, the best of which are, the Broad-leaved Batavian, Narrow-leaved Batavian, and Lettuce-leaved Batavian. Of Curled subvarieties, Large Green Curled, Small Green Curled, White Curled, Italian Green Curled, and Triple Curled Moss.

A sowing may be made in the beginning of June, and another in July, the seeds being scattered very sparsely, that the plants may not come up in clusters. The seedlings are transplanted into a rich soil, and are arranged in rows twelve or fifteen inches asunder, and at the distance of ten inches in the row. Sometimes they are planted in drills to facilitate the operation of blanching. The latter crop should be placed in a sheltered situation, where it may be able to withstand the winter. When the plants have reached their maturity, the leaves are gathered up, and tied together an inch or two below the tips, and afterwards about the middle of the plant. In two or three weeks they are found sufficiently blanched for use. In winter it is necessary to draw the earth quite up about the leaves. At that season, too, the plants may be inserted into a sloping bank of earth, or blanched in boxes in the Mushroom-house, or in a cellar.

Succory (*Cichorium Intybus*) is an indigenous plant, the cultivation of which may be said to have been introduced by the foreign refugees during the French revolutionary war. By the French it is much esteemed as a winter salad, and when blanched, is known by the name of *Barbe du Capucin*. When intended for winter use, the seed is sown in May or June, commonly in drills, and the plants are thinned out to four inches apart. If at first the leaves grow very strong, owing to wet weather, they are cut off perhaps in the middle of August, about an inch from the ground, so as to promote the production of new leaves, and check the formation of flower-stems. About the beginning of October the plants are raised from the border; all the large leaves are cut off; the roots are also shortened. They are then planted pretty closely together in boxes filled with rich light mould, and watered when needful. When frost comes on, the boxes are protected by any kind of haulm. As the salad is wanted, they are removed into some place having a moderately increased temperature, but with little light, such as a Mushroom-house or cellar off the kitchen. Each box affords two crops of blanched leaves, and these are reckoned fit for cutting when about six inches long. The roots of this plant, it may be added, have been employed as a substitute for coffee-beans, and in Flanders, and some parts of France, a portion of them is very often mixed with coffee.

Parsley (*Apium Petroselinum*) is a biennial plant, of well-known use in cookery. It is said to be a native of Sardinia, but it now grows spontaneously in various parts of Britain. The varieties are the Common, the Curled-leaved, and the Hamburg, the last of which is cultivated for the sake of its tuberous roots. Parsley loves a light rich soil. It is sown in drills about the beginning of March, and the seed lies some weeks in the ground before the plants appear. As they grow up they are thinned out, and are defended by branches or other coverings from hard weather in winter. The Hamburg variety being cultivated for its roots, is sown about the same time in a well trenched soil, in drills a foot apart, and it is thinned to about nine inches in the rows. In the beginning of November the roots are taken up and stored in sand.

Celery (*Apium graveolens*) is a native biennial, an inhabitant of the sides of ditches near the sea. In its wild state it is of an acrid nature, and of a coarse rank flavour; but by cultivation it is improved into one of the most agreeable salads. There are two principal varieties; *celery* properly so called, with upright stalks and fibrous or slightly tuberous roots; and *celeriac* with large turnip-shaped roots. Of the former, the principal subvarieties are:—

Cole's Superb Red, Cole's Superb White, Lion's Paw, Seymour's White Champion, Nutt's Champion, Manchester Giant Red, Wall's White, Cole's Crystal White, and Cole's Dwarf Red.

Celery is usually sown at three different times; on a hot-bed in the beginning of March, and in the open ground in March, and again in April. The seedlings, when about two inches high, are pricked into rich soil, in which they are allowed to stand till they are four or five inches high. The first crop is defended by frames or hand-glasses, and is planted wide to admit of being lifted with balls of earth adhering to the roots. Towards the end of May trenches for blanching the celery are prepared. These trenches are three and a half or four feet apart, fifteen inches wide at the bottom, and about a foot below the natural level of the surface. The soil at the bottom of the trench is carefully digged and manured, and a single row of plants is placed in each trench. Sometimes where a large supply is required, the trenches are made six feet wide, and after a similar preparation, rows fifteen or eighteen inches apart are planted across the trenches. As the plants advance in growth, earth is laid up about the stalks of the leaves, an operation which is repeated at the end of every ten or fifteen days, care being taken not to choke the plants. Many delay the earthing up until the plants have nearly attained their full size, when the operation is performed at once, and it is believed that by this process the stalks are rendered more crisp and tender. As the celery approaches maturity, scarcely any thing but the tips of the leaves appear above the ridges, and, when lifted, the stalks are found to be completely blanched. Successional crops should be planted out from the 1st of June till the 1st of August. Celery loves a rich light soil and an abundance of moisture.

Celeriac, or turnip-rooted celery, is treated at first like the early crop of common celery. In the beginning or middle of June it is planted out in a flat bed, in drills fifteen inches apart. A single earthing afterwards suffices. Its large round roots are used in soups, and are much relished by some. It is, however, more attended to in France and the Low Countries than in Britain.

Garden Cress (*Lepidium sativum*), and White Mustard (*Sinapis alba*) are generally associated in their use as salads, and in their culture in the garden. They are annual plants, and are eaten only when very young. In winter they may be raised on a slight hotbed, or in shallow boxes or pans placed in a temperature of 60° or 65°, in spring under hand-glasses, or in drills near a south wall, and in summer, when they should be sown once a fortnight, in drills, in any cool shady situation. Table mustard (which is made from *Sinapis nigra* L.), belongs rather to the department of agriculture. Durham mustard, which is distinguished for its pungency, though not remarkable for fine colour, is said to be made principally from the seeds of the common yellow field mustard or charlock (*Sinapis arvensis* L.)

Of Rhubarb (*Rheum*), several species and many varieties are cultivated for the purpose of supplying materials for tarts, the foot-stalks of the leaves being well adapted for that purpose, and coming into use at a most convenient season. R. *rhaponticum* and *palmatum* were the species first employed; but the sorts now preferred are seminal varieties, mostly allied to *R. hybridum* and *R. undulatum*. The following are the most worthy of notice:—

Myatt's Victoria, Myatt's Linnæus, Royal Albert, Britannia, Goliath, Elford or Buck's Early Scarlet.

They may be multiplied by dividing the roots, and this is the common practice; but they thrive much better when grown from seed. Sir Joseph Paxton recommends sowing on a slight hotbed in spring, and transplanting out in rows in the month of May. No stalks are gathered from them for the first two years, but in the third season they are fit for use. A portion of the crop is allowed to come on under the general influence of the season; but much also is forced, which may be done in a variety of ways. Some treat it like sea-kale, covering the root, which is allowed to remain in the ground, with a large pot or box, and wrapping it round with litter. Others take up the roots in autumn, pot them, and force them in the pits or Mushroom-houses. The best method is to procure long narrow boxes of a moderate depth, and to place them, packed full of roots, in a Mushroom-house or cellar, where there is a considerable temperature. The rhubarb soon throws up its stalks, and these being partially etiolated, possess a delicacy and flavour superior to those grown in the open air. It is easy, by varying the time of subjecting the boxes to the increased temperature, to keep up a succession of rhubarb stalks, from the period at which kitchen apples become scarce or begin to lose their flavour, till green gooseberries come into season.

The following annual plants are occasionally used in cookery, or as salads:—*Chervil*, Scandix cerefolia; *Purslane*, Portulaca oleracea; *Lamb's-lettuce*, Fedia olitoria; *Indian Cress*, Tropæolum majus; *Marigold*, Calendula officinalis; *Borage*, Borago officinalis. These may be sown in spring, or in the beginning of summer, in any fresh light soils. In general a small quantity will suffice.

The *Common Sorrel*, Rumex acetosa; and the *French Sorrel*, Rumex scutatus, which should give place to the Large Dutch; and the *Horse-radish*, Cochlearia Armoracia, are perennials, and are increased by parting their roots. They thrive in any cool shady situation.

The *Capsicum* or *Chile*, Capsicum annuum, and the *Love-Apple*, Solanum Lycopersicum, are tender annuals from tropical climates. Both are sown in hotbeds in spring, and after being transplanted and nursed in separate pots, are planted out, the former in a warm border, and the latter against a wall. In Scotland the Capsicum will scarcely mature its fruit without the aid of glass.

Dill, Anethum graveolens, and *Angelica*, Angelica archangelica, are umbelliferous biennials, which have been for a long period, though not extensively, cultivated in our gardens. They are easily raised from seed. With these may be associated the beautiful perennial, *Fennel*, Anethum Fœniculum, used in salads and sauces. It may be propagated either by parting the roots, or by seeds, which should be sown in autumn soon after they are ripe.

In every garden there is a small department set apart for the culture of Sweet Herbs and Medicinal Plants. We need not here enter into details respecting their uses or culture, but shall merely give classified lists.

Shrubby Plants increased by parting the roots, or by cuttings:—*Thyme*, Thymus vulgaris; *Sage*, Salvia officinalis; *Winter Savory*, Satureja montana; *Rosemary*, Rosmarinus officinalis; *Lavender*, Lavandula Spica; *Hyssop*, Hyssopus officinalis; and *Rue*, Ruta graveolens.

Perennial Herbaceous Plants, increased by parting the roots:—*Spearmint*, Mentha viridis; *Peppermint*, M. piperita; *Pennyroyal*, M. pulegium; *Balm*, Melissa officinalis; *Tarragon*, Artemisia Dracunculus; *Tansy*, Tanacetum vulgare; *Costmary*, Balsamita vulgaris; *Chamomile*, Anthemis nobilis.

Biennial or Annual Plants, increased by sowing the seeds:—*Clary*, Salvia Sclaria; *Coriander*, Coriandrum sativum; *Caraway*, Carum Carui; *Sweet Marjorum*, Origanum majorana; *Summer Savory*, Satureja hortensis; *Sweet Basil*, Ocimum basilicum; and *Bush Basil*, O. minimum. These last, the basils, which are natives of the East, and in much request for their delicate flavour, are raised on hotbeds in spring, and transplanted with balls, into some warm situation. In Scotland, they are mostly treated as tender annuals, and are grown, under glazed frames, in flowerpots.

There are besides a few others, which, in each of the classes, more properly belong to Dietetics, and Materia Medica. The young green leaves of Prunus Laurocerasus (under the name of laurel), may properly enough be employed in garnishing; but they ought never to be used, as they too often are, for giving a nutty flavour, or for *greening* other articles; hydrocyanic acid being given out and proving injurious, even in small quantities.

THE FLOWER GARDEN.

The cultivation of flowers, if not the most useful, is at least one of the most pleasing occupations of the horticulturist, and has generally shared largely in his attention. It is probable that at first, flowers, as objects of curiosity, were confined to a few patches or borders in the garden, as is still the case in many old places; but in the progress of art, and the diffusion of taste, separate departments were allotted to them under the name of Flower Gardens. After some general remarks on style and situation, we shall treat of the component parts of flower gardens, their various decorations, and of floriculture.

The designing of flower gardens unquestionably belongs to the fine arts, involving in it, the exercise of invention, taste, and foresight. Its principles are more vague and evanescent than those of any of the sister arts. The hand of the designer is not here guided by the imitation of nature, for his work is wholly artificial in its arrangements and appliances; neither does utility come in, as in architecture, to supply a form and frame-work, which it is the artist's part to adorn. "As flower gardens," says Loudon, "are objects of pleasure, the principle which must serve as a guide in laying them out, must be taste. Now, in flower-gardens, as in other objects, there are different kinds of tastes; these embodied are called styles or characters; and the great art of the designer is, having fixed on a style, to follow it out unmixed with other styles, or with any deviation which would interfere with the kind of taste or impression which that style is calculated to produce. Style, therefore, is the leading principle in laying out flower gardens, as utility is in laying out the culinary garden. As objects of fancy and taste, the styles of flower gardens are various. The modern style is a collection of irregular groups and masses, placed about the house as a medium, uniting it with the open lawn. The ancient geometric style, in place of irregular groups, employed symmetrical forms; in France, adding statues and fountains; in Holland, cut trees and grassy slopes; and in Italy, stone walls, walled terraces, and flights of steps. In some situations these characteristics of parterres may, with propriety, be added to or used instead of the modern sort, especially in flat situations; such as are inclosed by high walls; in towns, or where the principal building or object is in a style of architecture which will not render these appendages incongruous. There are other characters of gardens, such as the Chinese, which are not widely different from the modern; the Indian, which consists chiefly of walks under shade, in squares of grass; the Turkish, which abounds in shady retreats, boudoirs of roses and aromatic herbs; and the Spanish, which is distinguished by trellis work and fountains; but these last gardens are not generally adapted to this climate, though, from contemplating and selecting what is beautiful or suitable in each, a style of decoration for the immediate vicinity of mansions, might be composed preferable to any thing now in use." It may, however, be remarked, that the flower garden properly so called, has generally been too much governed by the laws of landscape-gardening, and these often ill-understood, and misapplied. In the days of "clipped hedges and pleached alleys," the parterres and flower-beds were of a description the most grotesque and intricate imaginable. At a subsequent period, when the natural and the picturesque became the objects of imitation in the park, there appeared the most extravagant attempts at wildness in the garden. The result has been unfortunate. It is not meant that when there are merely a few patches of flowers by way of foreground to the lawn, they should not be subordinated to the principles which regulate the more distant and bolder scenery; but wherever there is a flower garden of considerable magnitude, and in a separate situation, it should be constructed on principles of its own. In such a spot, the great object must be to exhibit to advantage the graceful forms and glorious hues of flowering plants and shrubs; and it is but seldom that mere elegancies in the forms of compartments, and other trickeries of human invention, can bear any comparison with these natural beauties. To express the peculiar nature of garden scenery, as distinct from the picturesque in landscape, Loudon has invented the term *gardenesque;* and, whatever may be thought of the term itself, it is very desirable that the distinction should be preserved.

Two varieties of flower gardens have chiefly prevailed in Britain; one, in which the ground is turf, and the pattern, so to speak, is composed of a variety of figures cut out of the turf, and planted with flowers and shrubs; and another, when the flower-beds are separated by gravel walks, without being interspersed with grass at all. The choice of one or other of these varieties ought greatly to depend upon the situation. When the flower garden is to be seen from the windows, or any other elevated point of view, from which the whole or the greater part of the design may be perceived at once, perhaps the former should be preferred. Where the surface is irregular, and the situation more remote, and especially where the beauty of flowers is the chief object of contemplation, the choice should probably fall on the latter. This variety, too, seems preferable, on the principle of contrast, where there are large lawns in the outer grounds, in order that *kept* (or smoothly mown) grass may not be found every where.

Respecting the situation of the flower garden, no very precise directions can be given, as it must be influenced by the nature of the lawns, and of the site of the mansion to which it is attached. Generally speaking, it should not be at any great distance from the house; and in places where there is no distant view of importance, it may be constructed under the windows. In retired scenes, it is delightful to step out of the drawing-room into compartments of flowers, in the vicinity of a greenhouse or conservatory. On the other hand, when the park is spacious, and the prospects extensive and picturesque, it is perhaps better that the flower garden should be at some distance, say not more than a quarter of a mile, and out of sight of the house, but with an easy access in any sort of weather; an arrangement which would give an agreeable termination to a short walk, a desirable matter in most cases, for it has been often remarked that many parts of extensive grounds remain unvisited, because they afford no remarkable object to attract the attention.

The particular form of a flower garden is equally beyond the inculcation of specific rules. Indeed, it may be of any shape, and, except where the dimensions are extremely limited, the boundaries should not be continuously visible. The taste of the proprietor or designer, and the capabilities of the situation, must determine not only the external configuration, but also the arrangement of the interior parts. By judicious management, it may be made to pass through shrubbery, gradually assuming a more woodland character, and groups of trees, into the park on the one hand, and into the kitchen garden or orchard on the other. In most cases, even when it is in the vicinity of the mansion-house, the flower garden should be encircled with some sort of fence, in order to convey the idea of protection, as well as to furnish security to the vegetable inmates of the parterres, it being impossible to carry on floriculture to any great extent in open places which are accessible to hares and rabbits. In detached localities, the fences may be made sufficiently strong to preclude the intrusion of every species of vagrant; and these it is not difficult to mask with shrubs and trees. The style of the mansion should determine that of the flower garden, and also its position. The flower garden attached to a highly architectural mansion, should, for the most part, occupy the lawn on the south, the east, or the west front; and the carriage-entrance, where possible, should be on the north front, the park extending close up to the front door. There are cases, however, where this arrangement must be departed from, and the flower garden must occasionally be placed even on the north front. These deviations are caused in a great measure by the difficulties of providing a proper approach to the entrance-door; and also by the position of the principal sitting-rooms, which should always command a view of the flower garden. A flower garden on the north front, if sufficiently distant from the house to prevent injury from shade, has this advantage, that the flowers will naturally turn towards the windows, whereas, when placed on the south front, their faces are directed towards the sun, and much of the effect of colour is lost. Flower gardens in connection with highly architectural mansions should be in the geometrical or systematic style, and bounded by parapet walls, with the appropriate mural decorations of ballustrading, piers, vases, &c. When upon a large scale, and especially where a natural inclination in the ground exists, or can be formed artificially, winding terraces and parapet walls should be introduced, with flights of steps, and the necessary embellishments in connection with them, as well as a profusion of fountains, statuary, sculpture, &c. Grass terraces have always a mean appearance in such a position. The parapet walls afford excellent accommodation for half-hardy and beautiful flowering plants.

Formerly the flower-beds were made either circular, straight, or in curves, and were turned into knots, scrolls, volutes, and other compartments; and this taste prevailed, perhaps, in some measure from a desire on the part of the contrivers, to compensate by their ingenuity for the paucity of the ornamental plants which they then cultivated. Now that the riches of Flora have poured into our gardens, a simpler taste has obtained. It is needless as well as impossible to specify the numerous configurations of flower-plots, for they abound in kaleidoscopical variety. Good taste will suggest that those only should be associated which harmonize well together; and it is better to incur the hazard of an apparent monotony, than to excite wonder by incongruous combination. When the figures are separated by turf, it is necessary that the little lawns or glades should have a certain degree of breadth, as nothing has a worse effect than overcrowding. A multitude of little figures should also be avoided, as they produce what Gilpin calls *spottiness,* and which, as he has correctly pointed out, is a grievous deformity. In this sort of flower garden, it is desirable that a gravel walk should skirt along at least one side of the principal figures; in our humid climate, the grass would otherwise render them inaccessible with comfort during a great part of the year. In those gardens in which turf is wholly or partly excluded, the compartments should be of a larger and more massive character. Narrow borders, bounded by parallel straight lines and concentric curves, should be avoided. The centres of the figures should be filled with tall-growing shrubs, and even with an occasional low evergreen tree, such as a yew or a holly. The walks, arranged in long concave

Flower Garden.

curves, may communicate here and there with one another. A dial, a few seats and arbours, with an urn or two or a vase, may be introduced with good effect. It is to be regretted that few good specimens of this species of flower garden have hitherto been executed in Britain.

Amongst the accompaniments of the flower garden may be mentioned the Rock-work. This consists of variously grouped masses of large stones, generally such as are remarkable for being figured by water-wearing, or for containing petrifactions or impressions; and into the cavities between the stones, filled with earth, alpine or trailing plants are inserted. In proper situations, a small piece of water may be introduced, for the culture of aquatic plants. One of the walks is sometimes arched over with wire-work, and covered with ornamental climbing shrubs, forming a delightful promenade in the glowing days of summer. A separate compartment, generally of a regular figure, is set apart for roses, under the name of the Rosary. A moist or rather a shady border, with bog earth, is devoted to that class of shrubs, commonly, but not very accurately, designated "American plants." In extensive places, a separate "American Garden" is often formed, in a locality which, if not damp, has at least the command of water, and occupies generally some warm corner of the park.

Some writers have advocated the formation of Winter and Spring Gardens in separate localities; but we are not aware that their ideas have ever been embodied to any great extent. It is proposed that in the winter garden should be assembled all the most beautiful evergreen shrubs and plants, together with the few flowers that bloom during the winter months. The situation, it is recommended, should be well sheltered, and open only to the warm rays of the sun, which are peculiarly grateful in our cold winter seasons. Masses of evergreens have a sombre and monotonous effect, even in winter, unless occasionally broken and varied by deciduous trees, which to some extent may be introduced. The contrast of these leafless neighbours relieves the intenseness of the gloom, and sets off the brilliancy of the rest. If the shrubs be grouped carefully according to their habits, instead of being planted promiscuously, the monotony will be softened down by the irregularity of surface which such groups present, and still more so when plants with variegated foliage are grouped together in masses proportionable to the extent of plantation. Though a winter garden, the very name of which is chilling, is perhaps in the estimation of some not very desirable by itself, the object to be attained in it should be kept in view in the formation of the park or flower garden. We can easily suppose a particular section of the latter to contain a predominance of evergreens, and to possess the principal characters of a winter garden, without the formality of its name and purpose. In the immense variety of situations, it is not difficult to imagine a sloping bank, for instance, facing the sun, with a long walk skirting its base, the lower side of which might be adorned with a border or narrow parterre planted with arbutus and periwinkle, whilst the slope is covered with the higher evergreens, and the summit of the acclivity is crowned with groups of deciduous trees, interrupted by a few straggling firs, through which the wind, unfelt below, might sigh its melancholy music. Again, the spring garden, which need not be of very great extent, may take refuge in the vicinity of the greenhouse or conservatory, with which it is naturally allied.

Soil.—A variety of soil is required in the flower garden, to suit the very different kinds of plants that fall to be cultivated. *American plants* require a peaty earth, varying from boggy peat to almost pure sand. Alluvial peat, that is, boggy earth which has been washed away and incorporated with white sand, is to be preferred; peat, cut from its natural bed and only partially decomposed, is of no value at all, or is positively prejudicial to plants. In collecting soil from the surface of a moor, it is proper to take no more than the upper turf or sod, with the peat adhering to it, and only from the driest parts of the ground, where, besides the common heath, fescue-grasses occur. Where this cannot be procured, a good substitute is found in vegetable mould, that is, decayed leaves swept from lawns or woods, and allowed to lie in heaps for a year or two. For the general purposes of the flower garden, a light loamy soil is advantageous; and where the natural covering is thin, or requires making up, recourse should be had to the surface-earth of old pastures, which, especially when incumbent on trap-rocks, is found to be excellent. It is expedient to have a large mass of this material in the compost yard. The turf, and the surface-soil adhering to it, should be laid up in a rough state, in which way it is continually ameliorating by the decomposition of the vegetable matters, and the action of the air.

Garden Walks.—During the prevalence of the Dutch taste, grass-walks were common in our gardens; but, owing to their frequent humidity in our climate, they have in a great measure disappeared. Their disuse is perhaps to be regretted, as in some situations, particularly behind lengthened screens of trees, or in gardens from which grass has been in a great measure excluded, an example or two of them would be agreeable. It is justly observed by Sir William Temple, that "two things peculiar to us, and which contribute much to the beauty and elegance of our gardens, are the gravel of our walks, and the fineness and almost perpetual greenness of our turf;" and therefore no trouble should be spared in securing excellence in these respects. In old times grass walks were formed with much care. After the space which they were to occupy had been digged and levelled that it might subside equally, a thin layer of sand or poor earth was laid upon the surface, and over this a similar layer of good soil. This arrangement was to prevent excessive luxuriance in the grass. In selecting the seed, all annual, wiry, and coarse sorts of grass should be avoided. The best mixture of grasses for this purpose, and their proportions per acre, is as follows, viz.:—Cynosurus cristatus, 5lbs., Festuca duriuscula, 3lbs., F. tenuifolia, 2lbs., Lolium perenne tenue, 20lbs., Poa nemoralis, $1\frac{1}{2}$lbs., Poa nemoralis var. semper-virens, $1\frac{1}{2}$lbs., Poa trivialis, $1\frac{1}{2}$lbs., Trifolium repens, 7lbs., and T. minus, 2lbs. This is also very suitable for lawns upon light soils.

Gravel-walks, in this department, are formed precisely in the same manner as those in the kitchen garden. It may, however, be remarked, that a multitude of gravel-walks, particularly when narrow, have a puny effect. All the principal lines should be broad enough to allow at least three persons to walk abreast; the others may be narrower. Much of the neatness of walks depends upon the material of which they are made. Gravel from an inland pit is to be preferred; though occasionally very excellent varieties are found upon the sea-coast. The gravel of Kensington and Blackheath has attained considerable celebrity; and is frequently employed in remote parts of the kingdom, the expense being lessened by its being conveyed to different sea-ports as ballast for ships. In summer a gravel-walk requires hoeing and raking from time to time, to clear it from weeds and tufts of grass. After this operation, or even after a simple sweeping, it is rolled down with a hand-roller; and this is repeated as often as the surface is ruffled. Nothing contributes more than frequent rolling to the elegance and convenience of garden walks.

Edgings.—Walks are generally separated from the borders and parterres by a variety of plants planted closely in line. By far the best edging is afforded by the Dwarf Dutch Box. It is extremely neat, and, when annually clipped, will remain in good order for many years. It may be planted at any season, except when in full growth or mid-winter. Excellent edgings are also formed by Sea Pink (*Statice Armeria*) and Double Daisy (*Bellis perennis.*) Dwarf Gentian (*Gentiana acaulis*) and London Pride (*Saxifraga umbrosa*) are also sometimes used. Indeed, any low-growing herbaceous plant, susceptible of minute division, is fitted for an edging. Edgings may also be formed of narrow pieces of sandstone flag, slate, fire-clay tiles, wire, or cast-iron. In shrubberies and large flower-plots, verges of grass-turf, from a foot to three feet in breadth, according to the size of the border and width of the walk, make a very handsome border to walks. These should not be allowed to rise high above the gravel: an inch and a half may be assigned as the limit they should not exceed. The grass is kept short by repeated mowings, and the edges are defined by clipping with shears, or cutting once a year with a paring iron.

Shrubs.—Much of the beauty of the pleasure garden depends upon the proper selection and disposition of ornamental trees and shrubs; and it is to be regretted that this department of the art has often been greatly neglected. In many gardens we still find only a few evergreens, and a parcel of rugged deciduous species, introduced probably before the age of Miller. No wonder is it, therefore, that we sometimes hear of the insipid scenes of the shrubbery. Nevertheless, shrubs are highly elegant in themselves, and they afford a most efficient means of diversifying garden scenery. Of the many beautiful species now to be had in Britain, and affording the materials of exquisite decoration, we can mention only a few.

Of Evergreens, besides the Common Laurel (*Prunus Laurocerasus*) and the Portugal Laurel (*P. lusitanica*), we may notice the American Arbor Vitæ (*Thuja occidentalis*), as adapted to large masses of shrubs; and the Chinese Arbor Vitæ (*T. orientalis*), whose size and mode of growth fit it for smaller compartments. The different varieties of Rhamnus Alaternus, and the species of Phillyrea and Juniperus, have long and deservedly been favourite evergreens. The Sweet Bay (*Laurus nobilis*), in favourable situations, rises into a handsome shrub or low tree, and may convey to the student of the classics an idea of the Delphic laurel. The Strawberry tree (*Arbutus Unedo*), a native of Ireland as well as of the south of Europe, will always find a place as one of the most elegant of plants, equally beautiful as regards foliage, flower, and fruit; nor should its countryman, the Irish Yew, ascending like the pillared cypress, be forgotten. The Cypress itself, though rather a denizen of the park, may be sparingly introduced. The Laurustinus (*Viburnum Tinus*), with blossoms approaching the snow in whiteness, enlivens the winter season, when nothing else is in flower in the shrubbery. The Swedish and Irish Junipers deserve a place. Different species of Daphne will not be forgotten; it may be sufficient to enumerate pontica, collina, Cneorum, and hybrida. As extremely low evergreens, we may mention Gaultheria procumbens and Shallon, Polygala Chamæbuxus, and Astragalus Tragacantha; but these would probably be better placed among what are popularly called American plants. Of the more tender evergreens, we should name the Andrachne (*Arbutus Andrachne*), a beautiful shrub, but liable to be injured by severe frosts. The Broad-leaved Myrtle (*Myrtus romana*), in warm places, and with the aid of a covering in the depth of winter, may be made to clothe the walls with its brilliant verdure for eight months in the year, and with its white flowers for some weeks in the end of summer. Aucuba japonica and Buxus balearicus are handsome shrubs, of a somewhat stronger constitution; the former is very ornamental in dull shady places, where no other shrub will grow. The beautiful tribes of Cistus and Helianthemum, some of which are quite hardy, are admirable for adorning sloping banks.

Amongst the shrubs that require a peaty soil, or at least a damp and shady situation, the splendid genus Rhododendron holds the principal place. Of the larger species may be mentioned R. ponticum, Catawbiense, and maximum, with their many beautiful varieties. In early spring, R. däuricum expands its blossoms among the first of flowering shrubs. Nor should we overlook R. punctatum, hirsutum, ferrugineum, and Chamæcistus, of humbler growth, but not inferior in beauty. With these the closely cognate genus of Azalea, with its multitudinous species and varieties, disputes the palm of elegance. The pale and drooping Andromedas are scarcely of inferior interest. The more recently introduced are the Taxodium, Cryptomeria, Torreya, Podocarpus, Dacrydium, and smaller growing Coniferæ. The hardy Heaths, particularly Erica carnea, Tetralix, and stricta, Menziesia polifolia and cœrulea, and the Canadian Rhodora, combine to bring up the rear of this department of Flora's train.

The deciduous flowering shrubs are too much neglected in many gardens. They are seldom well managed, either in point of arrangement or in the evolution, by pruning, of picturesque effect. Very often they are huddled together promiscuously, and grow up into the shape of huge sheaves of rushes. With judicious management, there is not a finer object in the vegetable kingdom than the common Lilac (*Syringa vulgaris*), or the hybrid var. (*S. rothomagensis*). Even the old Guelder-Rose (*Viburnum Opulus*) is worthy of the poet's eulogy; the "scentless rose," which he describes as "tall,"

> "And throwing up into the darkest gloom,
> Of neighbouring cypress, or more sable yew,
> Her silver globes, light as the foamy surf
> That the wind severs from the broken wave."

It would lead us into disproportioned detail to specify a tithe of those showy shrubs which should be dear to every floriculturist. Suffice it to name Ribes sanguineum, Daphne Mezereum, Spartium of many species, Cytisus, Amygdalus, and Pyrus. The Ribes speciosum, or Fuchsia-flowered gooseberry, seems to require the protection of a wall, but deserves it. The fine suffruticose plant Pæonia Moutan, requires the most sheltered position in the shrubbery, where, in May and June, its flowers excel all others in magnificence.

There are many fine climbing shrubs, such as the species of Clematis, and of Lonicera or Honeysuckle. Others, though not precisely of this class, are much beholden to the shelter of a wall, such as the beautiful Magnolia conspicua, Edwardsia tetraptera, microphylla, and grandiflora, Glycine sinensis, Eccremocarpus scaber, and Jasminum nudiflorum. The numerous species or varieties of Fuchsia, Escallonia, and Ceanothus, when planted against a wall, or even in the open ground, and shaded with an occasional covering in winter, convey to us a better idea of the riches of Chilian vegetation, than when they are confined to the shelves of the greenhouse. Many roses are also well adapted for walls, such as the varieties of Noisette, Boursault, and the different species from China.

Flower Garden.

A separate compartment, called the Rosary, is generally devoted to the cultivation of roses. It is often of an oval or circular form, with concentric beds, and narrow intervening walks of grass or gravel, but it may assume any configuration which is suited to display this favourite plant. Of the thousand varieties of roses which exist in the nurseries, we pretend not to give any selection. It may, however, be remarked, that in planting the Rosary, care should be taken to classify the sorts according to the sizes and affinities, otherwise the effect will be much impaired. The climbing sorts may be advantageously introduced, being trained to pillar-like trellises. When the rosary is extensive, it is judicious to intersperse some of the most showy hollyhocks; for thus the beauty of the quarter is maintained in the later months of autumn, when the roses are chiefly past. Standard roses are well adapted to stand singly on the little lawns in flower gardens, or to break the uniformity of low flower borders.

Nearly all shrubs may be propagated by layers, some by budding or grafting, many by separating the roots. In planting, shrubs may be arranged either singly or in masses: the latter method is the most efficient in the production of effect, but it should not be very servilely adhered to, as it is apt to beget monotony. Some kinds should never appear in masses: the white Portugal broom, for instance, when so arranged, gives a limy tint to a garden. Perhaps it is better that groups should contain a predominance of one shrub, set off by a few others of a contrasting figure or colour, than that they should be entirely homogeneous.

Herbaceous Plants.—Common perennial flowers, whether strictly herbaceous or bulbous, afford the principal materials for floral decoration. Botany supplies, as it were, the colours for the picture, and gardening grinds and prepares them for use. The painting is continually varying, and new shades are arriving and departing in succession. The least consideration of the subject will suggest the rule, that in planting flowers they should be arranged according to their stature, otherwise many of the most beautiful little flowers would be lost among their taller compeers. The lowest plants should therefore stand next the margin of the border or parterre, and they should increase in height as they go back. To produce a full show, a profusion, just not amounting to crowding, is requisite. The flower-plots should present a regular bank of foliage and blossom, rising gradually from the front; but as this might convey an idea of too great precision, a few *staring* plants, on the same principle as those employed in greenhouses, should be thinly scattered over the surface. These may be shrubs, or any tall showy plant, such as Bocconia cordata, Papaver bracteatum, Gladiolus Byzantinus, or Lilium candidum. The management of colour is more difficult. When the length of the flowering season is considered, it will be obvious that it is impossible to keep up the show of a single border or plot for six months together, and consequently that much of the labour employed in mixing colours is misspent, since plants, as they are commonly arranged, come dropping into flower one after another; and even where a certain number are in bloom at the same time, they necessarily stand apart, and so the effects of contrast, which can be perceived only among adjacent objects, are entirely lost. To obviate this defect, it has been recommended that ornamental plants should be formed into four or five separate suites of flowering, to be distributed over the garden. Not to mention the more vernal flowers, the first might contain the flora of May; the second that of June; the third that of July; and the fourth the tribes of August and the following months. These plants should be kept in separate compartments, arranged either singly or in masses; but the compartments themselves should be so intermingled, as that no particular class should be entirely absent from any one quarter of the garden. The May parterres should, however, chiefly occur in the vicinity of the greenhouse or conservatory, or, when these are absent, in a warm sunny situation. The flowerings of June and July, as being highly showy, should occupy the most conspicuous parts of the garden. The autumnal perennials, not being so imposing, may retire into the more secluded situations, as they are supplanted by the superior brilliancy of the annuals, which fill the vacant beds of florists' flowers, or are scattered over the faded clumps of May and June.

Flower Garden.

Before attempting to plant, the floriculturist would do well to construct tables or lists of flowers, specifying their respective times of flowering, their colours, and altitudes. These tables, when skilfully used, would prevent mistakes, produce a greater facility of execution, and put the colours nearly as much under control as they are on the painter's pallet. To diversify properly and mingle well together the reds, whites, purples, yellows, and blues, with all their intervening shades, requires considerable taste and powers of conception; but if success is not attained in the first attempt, inaccuracies should be noted, and rectified at the proper time next season. Certain series of colours have been given, but these it is needless to mention, as it is quite immaterial whether the first flower in a row be red or white. The principal object is to preserve an agreeable contrast; and as at particular seasons a monotony of tint prevails, it is useful at such times to be in possession of some strong glaring colours. White, for instance, should be much employed in July, to break the duller blues and purples which then preponderate. Orange, too, is very effective at this season. On the other hand, yellows are superabundant in autumn, and therefore reds and blues should then be sought for.

Besides mere vividness of colour and elegance of form, there are other qualities which render plants desirable in the flower garden. Whoever has visited a botanic garden, must have been sensible of an interest excited by the curious structure or by the scarcity of some plants. Even quaintness of form is deserving of attention. The writer of this article has seen Allium fistulosum (the common Welsh onion) making a conspicuous figure in a flower garden; and he remembers well a plant of seakale (*Crambe maritima*), which the good taste of the owner had introduced into the parterre, to the great disturbance of the ideas of the gardener. At the same time, it must be admitted that such expedients should be employed with reserve. No handsome plant should be rejected because it is common, nor any inconspicuous weed preserved merely because it is scarce. The flower-gardener should have a small nursery, or reserve garden, for the propagation of finer plants, to be transferred into the borders as often as is required.

We shall enumerate merely the names of a few of the most showy flowers, adapted to the British flower garden.

Vernal Herbaceous Plants.—Helleborus niger, lividus, olympicus, atrorubens; Eranthis hyemalis; Hepatica triloba var.; Primula vulgaris var., veris, elatior, marginata, helvetica, nivalis, viscosa, integrifolia, cortusoides; Cortusa Matthioli; Soldanella alpina, Clusii; Viola odorata, tricolor, biflora, altaica; Dodecatheon Meadia vars.; Orobus vernus; Adonis vernalis; Omphalodes verna; Corydalis lutea, longiflora; Sanguinaria canadensis; Iris pumila; Anemone apennina, Halleri, Pulsatilla.

Vernal Bulbous Plants.—Galanthus nivalis; Leucojum vernum; Crocus, species; Cyclamen coum, vernum; Corydalis bulbosa; Erythronium dens canis; Narcissus Pseudo-narcissus, moschatus, odorus, Jonquilla, &c.; Fritillaria imperialis, meleagris, persica;

Flower Garden.

Gagea lutea; Tulipa sylvestris; Iris persica; Trillium grandiflorum, &c.; Scilla verna, præcox, bifolia, sibirica.

Herbaceous Plants flowering in May.—Anemone narcissiflora, sylvestris, dichotoma; Primula farinosa, scotica; Convallaria majalis; Uvularia grandiflora, perfoliata; Phlox verna, divaricata, subulata, setacea, &c.; Asphodelus luteus, ramosus; Draba aizoïdes; Viola cornuta, obliqua; Gentiana verna, acaulis; Lupinus polyphyllus; Gaillardia bicolor; Iris florentina, cristata, &c.—*Bulbs:* Leucojum æstivum; Scilla non-scripta, italica, &c; Hyacinthus monstrosus; Muscari moschatum, botryoides, comosum; Narcissus Bulbocodium, poëticus, &c.

June—Herbaceous Plants.—Pæonia officinalis, albiflora, corallina, Humei, &c.; Dianthus, species; Geranium sanguineum, Lancastriense, Wallichianum, striatum, &c.; Monarda didyma, Kalmiana; Papaver bracteatum; Saxifraga, species; Spiræa, species; Mimulus luteus, moschatus; Trollius americanus, europæus; Lysimachia verticillata; Veronica latifolia, &c.; Geum coccineum; Aconitum Napellus, &c.; Potentilla nepalensis, &c.—*Bulbs:* Allium Molle; Gladiolus byzantinus, communis; Lilium Pomponium, bulbiferum, aurantiacum, monadelphum, penduliflorum, concolor, &c.; Iris Xiphium, xiphioides, &c.

July—Herbaceous Plants.—Phlox intermedia, and many other species of that fine genus; Pentstemon, numerous species; Œnothera, various species; Campanula persicifolia, &c.; Asclepias amœna, syriaca; Iris fulva, pallida, variegata; Gentiana lutea, asclepiadea, cruciata, septemfida, &c.; Chelone obliqua, barbata, Lyoni.—*Bulbs:* Lilium Martagon, canadense, tigrinum, superbum, &c.; Gladiolus cardinalis; Tigridia pavonia; Commelina cœlestis; Cyclamen hederæfolium.

Autumnal Herbaceous Plants.—Phlox decussata, pyramidalis, tardiflora, &c.; Lobelia cardinalis, fulgens, splendens, &c.; Aster sibiricus, amellus, pulcher, &c.; Eschscholtzia californica; Solidago, several species; Aconitum japonicum, volubile, variegatum; Gentiana Saponaria: Pentstemon, several species.—*Bulbs:* Colchicum autumnale; Crocus nudiflorus, serotinus; Tritoma pallida, media, riparia, Burchellii.

It is with regret that we thus confine ourselves to a dry list of border flowers; but to do them any thing like justice, would require many pages. Within the last few years great accessions have been made to our stores. The Lupins and Pentstemons from the Columbia River, the Verbenas and Calceolarias from South America, and the Potentillas and Geraniums from Nepal, have in a great measure changed the face of our flower gardens, while the industrious florist has added an almost countless number of hybrid productions, combining every shade of colour and diversity of form. While thus our riches have increased, the difficulty, as well as the necessity, of making a selection has increased also.

Most herbaceous perennial plants are propagated by parting the roots, or by cuttings; but some most conveniently by the sowing of seed.

Biennial Plants—Plants whose existence is limited to two years, in the latter of which they flower and then decay, are called biennials. Many of them possess considerable beauty; and by their easy propagation and rapid growth, they afford a ready means of decorating borders. The following may be considered most worthy of notice:—Agrostemma coronaria; Antirrhinum majus; Hedysarum coronarium; Lunaria biennis; Campanula media; Œnothera sinuata, biennis; Verbascum formosum; Hesperis matronalis; Scabiosa atropurpurea; Matthiola simplicicaulis. When a very desirable variety is procured, such as the striped Antirrhinum majus, attention should be paid to the striking of cuttings during the summer, as the only means of continuance.

Biennials are sown in beds in the end of spring, and are generally transplanted in the course of the autumn, into the places where they are intended to stand, that they may be confirmed before winter, and shoot up readily into flower in the following summer.

Annual Plants.—Many of the annual species, though of fugitive duration, are possessed of much beauty of hue and elegance of form. They are further valuable from their pliability, so to speak, and the promptitude with which they may be used. They are besides of easy culture, many requiring nothing more than to have the seeds sown in the spot where they are to grow. Annuals may be divided into three classes, the *hardy*, the *half-hardy*, and the *tender*. The first class, as stated above, are sown at once in the ground which they are to occupy; the *half-hardy* succeed best when aided at first by a slight hotbed, and then transplanted into the open air; the tender are kept in pots, and treated as greenhouse or stove-plants, to which departments they properly belong. It is scarcely necessary to remark that the *hardy* and *half-hardy* sorts may be grown either in patches or in beds, and are subjected to all the rules which regulate the disposition of common border flowers.

Hardy Annuals.—Anagallis; Bartonia; Calliopsis; Iberis umbellata; Knautia orientalis; Alyssum, several species; Linaria, various species; Delphinium Ajacis, consolida; Silene Armeria; Campanula speculum, Lorei; Lavatera trimestris; Malope trifida, Hibiscus trionum, bifrons; Nolana, various species; Papaver somniferum, numerous varieties; P. Rhœas, varieties; Gilia capitata, tricolor; Collinsia grandiflora; Kaulfussia amelloides; Clarkia pulchella, elegans; Œnothera rosea, rosea-alba, tenella, Lindleyana, Romanzovii; Rudbeckia amplexicaulis; Senecio elegans; Matthiola annua; Lupinus, several species; Godetia; Nemophila; Lasthenia; Leptosiphon; Oxyura; Platystemon; Saponaria; Silene, &c.

Half-hardy Annuals.—Callistemma hortense; Lopezia racemosa; Tagetes patula, erecta, racemosa, &c.; Zinnia elegans, pauciflora; Xeranthemum annuum; Helichrysum fulgidum; Chrysanthemum carinatum; Amaranthus caudatus; Schizanthus pinnatus, porrigens, Grahami, Hookeri; Salpiglossis atropurpurea, straminea; Petunia nyctaginiflora; Mirabilis Jalapa; Ageratum; Argemone; Brachycoma; Chænostoma; Clintonia; Cuphea; Grammanthes; Hemimeris; Lotus; Phlox; Rhodanthe; Podolepis; Portulaca; Senecio; Talinum, &c.

Tender Annuals.—Impatiens Balsamina; Browallia elata; Celosia cristata; Gomphræna globosa; Solanum melongena; Mesembryanthemum crystallinum.

We have been able to enumerate only a small selection of species out of a multitude which is continually receiving accessions. Many of the sorts mentioned above have been introduced during the last few years; and we doubt not that, at no distant period from the present, many more will come into notice.

Before leaving this part of the subject, it may be proper to mention that it is now the practice to grow and treat as annuals, or rather as biennials, great quantities of the more hardy Pelargonia, Verbenæ, Salviæ, Calceolariæ, Fuchsiæ, Hemimeres, and other genera. Many gardeners every season propagate, by cuttings, or seeds, several thousands of these plants. Grown in moderate-sized pots, they are kept in cool pits, yet protected from frost during winter. About the end of May, or as soon as there is no longer any apprehension of injury from frost, the plants are taken out of the pots and planted in the open ground in the flower garden. Some cultivators shift their plants, particularly scarlet geraniums, into pots nine or ten inches in diameter, in spring, and plunge them into the parterres instead of planting them out, with a view to lessen the size of the foliage, and induce a disposition to a more profuse production of bloom. Towards the middle of July they begin to grow vigorously, and in August or September present, in luxuriance at least, if not in magnitude, a better representation of their native vegetation than we see elsewhere in our gardens. Upon the approach of frost, they are, with the exception of the Fuchsias, taken up and potted and placed in pits till the following season, at least the best grown plants are, and a supply is also secured by striking them for cuttings during July and August. These plants, with the fine new annuals, and the gorgeous Dahlias, give a splendour to the autumnal flower garden which in former times it did not possess.

Florists' Flowers.—This technical appellation has been restricted to certain flowers, which have been especial favourites with florists, and have consequently received a large share of their attention. Though possessed of great individual beauty, few of them are calculated to make a show at a distance, and the arrangements requisite for their culture do not harmonize well with the general disposition of a flower garden. It is, therefore, desirable, particularly when considerable refinement is aimed at, that a separate garden, or a separate section of the garden, should be set apart for their culture. The more robust or less valuable varieties, however, which are often as showy as the most esteemed, may be introduced into the general parterres. We shall notice the most considerable, in the order in which they naturally attract attention.

The *Hyacinth* (*Hyacinthus orientalis*), one of the most beautiful and fragrant of the spring flowers, is a native of the Levant, where it occurs abundantly, in form not unlike our common harebell. It has long been a favourite in the East; but it has been brought to its present artificial perfection in Holland, chiefly since the beginning of last century. The catalogues of the Haarlem florists used formerly to enumerate 2000 sorts, some of which sold as high as £200 a bulb; they are now less numerous, and much less expensive.

Hyacinths are either single, semidouble, or double, and exhibit a great variety of tint.

The criterion of a perfect flower of this sort is given by Mr Glenny, in his little work on the "The Properties of Flowers and Plants."

"Each pip or flower should be round, and not ragged. The petals should be broad, thick, blunt at the ends, not pointed, and reflex enough to threw up the centre well. The foot-stalk should be strong, and hold the flower out stiff in a vertical position, and by no means weak, to allow the pip to hang with the face sloping downward. The foot-stalk should be of a length to make the pips touch and no more. The pips should be large, and the flowers close on the stem. Double flowers should have the rows of petals above each other very regularly imbricated, so as to throw up the centre. The spike should be bold, round, compact, and pyramidal. The flower should be very strong, and diminishing to a single flower at top. The flower-stem should be very strong and upright, and no part of it should be seen in consequence of the closeness of the pips to each other. The colours should be bright, clear, and dense, whatever the shade, and any better approach to scarlet, blue, or yellow, than those shades we now possess, would be highly esteemed."

The hyacinth delights in a rich light sandy soil; and it is chiefly owing to the want of these qualities in his composts, that the British florist fails in the growth of this beautiful plant. The Dutch compost is the following:—One-third coarse sea or river sand; one-third rotten cow-dung without litter; and one-third leaf mould. The natural soil is removed at least two feet deep, and the vacant space filled up with compost, previously prepared and well mixed. These materials retain their qualities for six or seven years, but the Dutch do not plant hyacinths upon the same place for two years successively. In the alternate years they plant it with narcissus or crocus.

About the 25th of October is the best time to plant the bulbs. They are arranged in rows, eight inches asunder, there being four rows in each bed. The bulbs are sunk about three or four inches deep, and it is recommended to put a small quantity of clean sand below and all around them. As the roots are liable to be injured by frost, it is usual to cover the beds with decayed tan-bark, with litter, or with awnings. The first may be considered the neatest during winter, but an awning is indispensable in spring, when the lingering colds prove exceedingly hurtful to the young flower-stems. As the flower-stems appear, they are tied to little rods, to preserve them from accident. In order to perfect the colours, the rays of the sun are admitted in the morning or in the evening, but the glare of mid-day and the cold of the night, are both excluded. When the season of blossom is over, the awning is removed or only replaced to keep off heavy rains. Much of the success, in the culture of this flower, depends on the subsequent management of the bulbs. It is the practice in Holland, about a month after the bloom, or when the tips of the leaves assume a withered appearance, to take up the roots, and, cutting off the stem and the foliage within half an inch of the bulb, but leaving the fibres, to lay the bulbs sideways on the ground, covering them with half an inch of dry earth. After three weeks, they are again taken up, cleaned, and removed to the store-room. In the store-room the roots should be kept dry, well-aired, and apart from each other.

Where forcing is practised, a few bulbs may be forced in deep flower-pots filled with light earth, and when coming into flower, transferred to the greenhouse, which they enliven at the deadest season of the year. In chambers, they are grown in water-glasses made for the purpose; or, with still greater advantage, in boxes filled with damp hypnum moss.

New varieties of hyacinths are procured by sowing the seed; but this is a tedious process, and seldom followed in this country. The established sorts are propagated by offsets or small bulbs, which form at the base of the parent bulb. Almost all the hyacinths cultivated in this country are imported from Holland, and the quantity of roots annually introduced must be very considerable.

The *Tulip* (*Tulipa Gesneriana*), is a native of the East, whence it was introduced into Europe about the middle of the 16th century. Gaudy as it is, it has no proper corolla, but only a calyx of six coloured sepals. About the year 1635 the culture of the tulip was very engrossing; and, indeed, the rage for possessing rare sorts had become so great in Holland, as to give rise to a strange species of gambling, known to the collectors of literary and scientific anecdotes by the name of Tulipo-mania, which has tended to bring unmerited discredit on this fine flower. At present the finer tulips are mostly of moderate price, and, though not to be met with in every garden, have yet some ardent cultivators.

There are some varieties, such as the early Duc Van Thol, the Clarimond, the Parrots, and the Double Tulips, which belong, properly speaking, to the general cultivator. In this country, the florists' tulips are arranged under four classes. 1. The *Bizarres*, which have a yellow ground marked with purple or scarlet. 2. The *Byblœmens*, with a white ground marked with violet or purple. 3. The *Roses*, with a white ground marked with rose-colour. 4. The *Self* or *Plain-coloured* tulips, which are of one uniform colour, and are chiefly valued as breeders. The Byblœmen class includes most of those tulips which are held in highest esteem in this country.

The properties of a fine late tulip, as specified by Mr Glenny, are the following, somewhat abridged:—

The cup should form, when quite expanded, from half to a third of a hollow ball. To do this the petals must be six in number; broad at the ends, smooth at the edges, and the divisions between the petals scarcely to shew an indenture. The three inner petals should set close to the three outer ones, and all being so close as to shew no openings between them. The petals should be smooth; thick and stiff, and should keep their form well. The ground colour should be clear and distinct, whether white or yellow. The least stain, even at the lower end of the petal, would render a tulip comparatively valueless. Whatever be the disposition of colours or marks upon a tulip, all the six petals should be marked alike, and be therefore perfectly uniform. The feathered flowers should have an even close feathering forming an unbroken edging, all round. If the flower have any marking besides the feathering at the edge, it should be a beam, or bold mark down the centre, but not to reach the bottom of the cup; the mark or beam must be similar in all the six petals. Flowers not feathered, and with flame only, must have no marks on the edges. None of the colour must break through to the edge. The colour must be perfectly uniform in all the petals, and not to go too near the bottom. The colour, whatever it be, must be decided, distinct in outline, and neither shaded, flushed, or broken. The height should be from 18 to 36 inches, the former is right for the outside row in a bed, and the latter is right for the centre or highest row.

Tulips prosper in a light sandy soil, similar to that for hyacinths, and their season of planting and after-management is so much the same as to require no separate notice here. After the sepals have fallen, the seed-vessels are broken off close by the stem, to prevent the plant from exhausting itself in perfecting seed, and to direct its energies to the forming of the new bulb. When the leaves have withered, the bulbs are taken up, dried, and stored until the planting season come round.

Tulips are readily propagated by offsets, which are taken off from the parent bulbs, and nursed in separate beds till they be full grown. New varieties are raised from seed; they are from five to seven years old before they flower, and, if raised from promiscuous seed, they often turn out worthless. Seedling tulips, it may be remarked, present this anomaly for the first two or three years, that they form their new bulbs several inches below the old ones, so that an inexperienced cultivator is sometimes apt to miss them at the time of lifting.

The *Ranunculus* (*R. asiaticus*) is, like many of the other florists' flowers, a native of the Levant, where it is a favourite of the Turks. It has sported into innumerable varieties, and those now in cultivation in this country are mostly of British origin.

According to the canons of floral criticism, laid down by Glenny, the properties of a fine double ranunculus are the following :—

> The flower should be of the form of two-thirds of a ball, two inches in diameter, and the upper part of it square or horizontal. The outline of the bloom should form a perfect circle. The petals should be thick, smooth on the edges, and gently cupped; they should lie close, so that little but the edges should be seen. The flower should be symmetrical to the centre, which should be close, so as perfectly to conceal the seed vessel. The colour should be very dense, whatever be its hue; if an edged flower, the edging should be well defined, and the marking even and uniform; in no case should the ground colour break through the edging; but spotted flowers with one spot on each petal are allowable. The stem should be strong, and long enough to raise the flower clear six inches above the foliage. Striped flowers are not perfect, nor are flowers speckled at the edges; they ought not to exhibit a single break.

The ranunculus requires a stronger and moister soil than most other flowers. Maddock preferred a fresh, strong, rich loam. Hogg recommended a fresh loam, with a considerable portion of rotten cow or horse dung. The Rev. Mr Williamson (Hort. Trans. vol. iv.) uses a stiff clay loam, with a fourth of rotten dung, and this compost is still used by more modern florists. "The bed should be dug from eighteen inches to two feet deep, and not raised more than four inches above the level of the walks, to preserve the moisture more effectually: at about five inches below the surface should be placed a stratum of two-year-old rotten cow dung, mixed with earth, six or eight inches thick; but the earth above this stratum, where the roots are to be placed, should be perfectly free from dung, which would prove injurious if nearer. The fibres will draw sufficient nourishment at the depth above mentioned; but if the dung were placed deeper, it would not receive so much advantage from the action of the air." The principal object, however, is to maintain throughout the bed a genial moisture; and this is to be done by avoiding all hot gravelly earths, and particularly soils that are apt to cake. The tubers are planted late in autumn or early in spring, in rows five or six inches apart, and three or four inches separate in the rows. They should be so close that the foliage shall cover the surface of the bed, for in this way a salutary degree of shade and moisture is preserved. The autumn planted roots must be sheltered from frost by old tan or sifted coal-ashes. When in flower, the plants are covered with an awning. When the leaves wither, the roots are taken up, dried, and stored.

Scarcely any florists' flower is more readily propagated from seed, or sooner repays the care of the cultivator. The seed is obtained from semi-double sorts, which are often of themselves very beautiful flowers. It is generally sown in boxes in autumn or spring. We have often seen it committed with success to the open ground. The young plants thus raised flower often in the second, and always in the third year.

The *Anemone* of the flower garden includes two species, Anemone coronaria, a native of the Levant, and A. hortensis, a native of Italy. These have long shared the attention of the florist, and in his arrangements have generally been associated with the ranunculus, resembling it in its natural affinities and mode of culture. In a fine double anemone, the stem should be strong, erect, and not less than nine inches high. The flower should be at least two and a half inches in diameter, consisting of an exterior row of large well rounded petals, in the form of a broad shallow cup, the interior part of which should contain a number of small petals, mixed with stamens, imbricating each other. The colours should be clear and distinct when diversified in the same flower, or striking and brilliant when there is only one tint.

The soil and culture are so nearly the same as in the ranunculus, that it is needless to specify them. The plant continues longer in flower, and the leaves often remain so long green, that it is difficult to find a period of inaction in which to take up the roots. It has been recommended, that as soon as the bloom is over, the bed should be screened from rain by mattings until the leaves wither. As the roots are rather brittle, they require considerable care in handling. Anemones are easily raised from the seed. A bed of single anemones, it may be remarked, is a valuable addition to a flower garden, as it affords, in a warm situation, an abundance of handsome and often brilliant spring flowers, almost as early as the snowdrop or crocus.

The *Narcissus* is an extensive genus, including a great many interesting species and varieties. It belongs, however, rather to the botanico-florist than to the florist proper; but as it contains many plants of great elegance, it ought to receive more general attention. The Polyanthus Narcissus (*N. Tazetta*) affords the varieties which are chiefly cultivated by florists. These prosper in a rich light soil, containing a little dung. The roots should not be stirred more frequently than once in three years; and this remark applies also to Narcissus Jonquilla and odorus, the small and large jonquil, of which fragrant plants there should be beds in every flower garden. N. Tazetta, like the hyacinth, may be grown either in pots or in water-glasses.

The *Lily*. Of the genus Lilium there are many species, some of which have not been exhibited to the extent of their capabilities in the flower garden. The old white Lily (*L. candidum*, L.), after supplying the poets with so much imagery, has retired into the modest station of a common border flower. The flaunting Orange-Lily (*L. bulbiferum*) may be allowed, if it pleases, to follow its example. L. Martagon may occupy the same place. The scarlet Turk's Cap (*L. chalcedonicum*) is worthy of more care, as being more beautiful and more tender. It does not relish being disturbed, and it dislikes peat. On the contrary, the splendid Tiger Lily (*L. tigrinum*), which propagates rapidly by axillary bulbs, succeeds best in peaty soil. The same remark applies to the rarer L. canadense, and superbum (magnificent species), as well as to L. concolor, pennsylvanicum, and others, which ought to be more common in our gardens. L. japonicum and longiflorum, in which the genus attains its greatest magnificence, unfortunately require a finer climate than ours, and must therefore be grown in pots under glass.

The same may be said of L. eximium, and the more recently introduced L. lancifolium and its hybrid varieties.

The *Dahlia*, of which there are two species (*D. variabilis* and *D. coccinea*), is a native of Mexico, from which it was introduced in 1789, but afterwards lost by our cultivators. It was reintroduced in 1804; but it was not till ten years later than it was generally known in our gardens. At present the varieties are endless, each district of the country possessing suites of its own, and cultivators occasionally raising at one sowing a dozen or two of sorts, which they think worthy of preservation. The results have been most propitious to the flower garden, from which, indeed, the Dahlia could nearly as ill be spared as the potato from the kitchen garden.

A perfect Dahlia flower, according to Glenny, should be circled, the petals should be broad at the ends, smooth at the edges, thick in substance, perfectly free from indenture or point, it should cup a little, but not enough to show the under surface. The flower should form two-thirds of a ball when looked at sideways. The petals should rise above one another symetrically, each petal covering the joinings of the two under it. The centre should be perfect, the unbloomed petals lying with their points towards the centre, should form a button, and also the highest part of the flower. The petals should open boldly, without showing their under side, and should form circular rows, uniformly laid, evenly opened, and enlarging by degrees to the outer row of all. The flower should be very double. The petals should cover one another very nearly; not more should be seen in depth than half the breadth; the more they are covered so as to leave them distinct, the better in that respect; the petals, therefore, though cupped, must be shallow. The size of the flower should be four inches in diameter, and not more than six. The colour should be dense, whatever it be, whether tipped or edged, it must be free from splatches and blotches, or indefinite marks of any kind.

New varieties are, of course, procured from seed. If sown in flower-pots, and aided by a little heat, the seedlings, speedily planted out, will flower the first season. Established varieties are propagated by dividing the large tuberous roots, but in doing so, care must be taken to have an eye to each portion of tuber, otherwise it will not grow. Sometimes shoots of rare varieties are grafted on the roots of others.

They are best, and most generally propagated by cuttings, and for this purpose, the old tubers are placed in heat in January, and as the young shoots, which rise freely from them, attain the height of three inches, they are taken off and planted singly in small pots filled with fine white sand, and plunged in a moderate heat. They root speedily, and are then transferred to larger pots in light rich soil. Their growth is encouraged until the planting out season arrives, which is about the middle of June.

Dahlias succeed best in an open situation, and in rich deep loam; but there is scarcely any garden soil in which they will not thrive, with manure. They are, however, injured by being repeatedly planted on the same spot. They may stand singly like common border flowers; but have the most imposing appearance when seen in masses arranged according to their stature. Old roots often throw up a multitude of stems, which render thinning necessary. As the plants increase in height, they are furnished with strong stakes, to secure them from high winds. Dahlias generally flower till they are interrupted by frost in autumn. The roots are then taken up, dried, and stored in a cellar, or some other place, where they may be secured from frost and moisture.

The *Auricula* (*Primula Auricula*) is a native of the Alps and the Caucasus. It has long been an inmate of our gardens; and has generally been a favourite with those florists whose means and appliances are of a limited kind.

Besides the double varieties which have never been in much repute, Auriculas are classed under two divisions: the *selfs* or plain-coloured, and the *variegated* or *painted* sorts. Professed florists confine their attention to the latter: it must, however, be confessed, that their criteria of fine flowers are often arbitrary, and that although many of their favourites are examples of undoubted beauty, the eye of the uninitiated would generally prefer the simpler hues of the self-coloured flowers.

The auricula, though now almost wholly an artificial plant, and strangely transformed from its original appearance, still loves a moist soil and shady situation. The florists' varieties are grown in rich composts, for the preparation of which numberless receipts have been given. We quote that of Mr Hogg, an experienced grower, as stated in his Supplement, p. 166. "One barrow of rich yellow loam, or fresh earth from some meadow or pasture land or common, with the turf well-rotten; one barrow of leaf mould, one ditto of cow-dung, two years old at least; and one peck of river, not sea sand. For strong plants intended for exhibition, add to the same composition, as a stimulant, a barrowful of well decayed night soil, with the application of liquid manure before the top-dressing in February, and twice more, but not oftener, in March. A portion of light sandy peat-earth may be added, as a safe and useful ingredient, particularly for plants kept in low damp situations." The treatment of modern growers does not differ essentially from this.

Auriculas may be propagated from seed. It is to be sown in January or February in boxes, which are kept under cover, and exposed only to the rays of the morning sun. When seed has been saved from the finer sorts, the operation is one of considerable nicety, as it not unfrequently happens that the best seedlings are at first exceedingly weak. They generally flower in the second or third year; and the florist is fortunate who obtains three or four good sorts out of a large sowing. The established varieties are increased by dividing the roots, an operation which is performed in July or in the beginning of August.

Fine auriculas are grown in pots about six inches in diameter. These are kept in frames, or stages constructed for the purpose. For winter use, perhaps there is nothing better than a common hot-bed frame, as this admits of an exact adjustment of air and temperature, things to which attention is absolutely necessary when the plants approach the flowering season. After the bloom is over, the pots may be placed on stages slightly elevated, and facing the north. Though not absolutely necessary, it is useful to have the power of sheltering them from long continued rains. It is usual every year to shift the plants, shortening the roots, and giving them a large portion of new soil, soon after the flowers have decayed.

The *Polyanthus* is supposed to be a seminal variety of Primula vulgaris, and is much cultivated by some florists. Like the auricula, it has sported into many hundred varieties. It is not necessary to give a detailed account of its culture, as it scarcely differs from that of the auricula. The polyanthus, however, is the hardier of the two, and seldom perishes from cold. It may be mentioned that there are several beautiful double varieties of the common primrose, which are deserving of a place in every garden.

The *Carnation* (*Dianthus caryophyllus*) has long been a favourite flower, not only for the beauty, but for the delightful fragrance of its blossoms. It is a native of Germany, and is occasionally found in an apparently wild state in England. The cultivation of it, however, is by no means easy, and calls forth all the resources of the florist. The varieties, which are very numerous, have been arranged under three heads: *Flakes*, having two colours, with their stripes running quite through and along the petals; *Bizarres*, irregularly spotted, and striped with not fewer than three colours; *Picotees*, spotted, with serrated or fringed petals. Mr Hogg, who wrote a treatise expressly on this flower, has given a catalogue of nearly 350 sorts.

Carnations are propagated by layers or pipings: the former method is most practised, but with some weak sorts piping should be preferred. Layering is performed when the plant is in full bloom. Proper shoots are selected; a few of the lower leaves are then removed; an incision is made a little below a suitable joint passing up through it, and the shoot is then pegged down and covered with some fresh soil, the tip being left above ground. Layers are generally found to be rooted in about a month after the operation has been performed. Pipings are little cuttings, separated at a joint, and planted thickly under bell-glasses on a slight hotbed. They require great attention, and are precarious in their success, but form excellent plants.

Numerous directions have been given respecting composts for carnations. These differ more in words than in material. The following is that generally employed:—Take three barrows of loam, one-and-a-half of garden mould, two of horse-dung, and one of coarse sand; let these be mixed, and thrown into a heap, and turned over two or three times in the winter, particularly in frosty weather. Towards the end of November a barrow-load of lime is added, while hot, to aid in the decomposition of the soil, and to destroy worms. For the varieties which are liable to sport, a poorer compost may be recommended.

The more robust carnations are planted out in beds or singly in the flower garden; but the finer and tenderer sorts are grown in pots of about a foot in diameter. The time of potting is about the end of March. When the flower-stems shew themselves, they are furnished with rods, to which they are tied as they lengthen, to prevent their being broken by the wind or other accident. When the plants begin to expand their blossoms, they are removed to a stage calculated to exhibit their beauties. Some florists attach ligatures of matting to the flower-buds, in order to prevent irregular bursting, and even arrange the petals, by removing distortions with scissors.

New varieties are raised from seed. The seed of the hardier double or semi-double sorts often affords a very beautiful bed of flowers, and should not be neglected by those who have the command of extensive flower gardens.

The *Pink* is considered by botanists as merely a variety of the preceding. It is, however, very distinct in its character, and constant in its habits. It is one of the mechanics' flowers, and is cultivated most extensively in the neighbourhood of some of the manufacturing towns. Its simple elegance does credit to the taste of those who select it for their favourite; and it deserves a place in the garden of the highest as well as of the lowest of the land. Pinks are numerous, growers enumerating about three hundred varieties. Those are preferred which have the limb of the petals nearly entire, and are well marked in the centre with bright crimson or dark purple.

Pinks are mostly propagated by pipings in slight hotbeds or under hand-glasses; and when proper attention is given to the due admission of air, they generally succeed. Rare sorts, which are scantily furnished with grass, are occasionally propagated by layers. This flower does not require such elaborate composts as some others, but it likes fresh light soils, well manured with decayed cow dung. Not more than two years of blooms should be taken from the same bed, and it is the practice of most florists to have a new bed every year. The flower stalks are supported by small sticks. As in the carnation, ligatures of matting, or collars of card, are sometimes applied to the calyces of the flowers: but this practice, however it may be followed by those who judge according to the technical "criteria of a fine flower," will scarcely be adopted by any who have an eye for natural beauty.

It would lead us too much into detail to speak minutely of Calceolaria, Phlox, Chelone, Pentstemon, Œnothera, Roses, Pansies, Cinerarias, Chrysanthemums, Lobelias, Verbenas, Picotees, Hollyhocks, Fuchsia, Petunia, &c., for all these are now considered as florists' flowers. To have them in perfection, they should be kept in beds by themselves; and we are persuaded that, were a moiety of the care bestowed upon some of the preceding flowers, which are conventionally supposed to belong peculiarly to the florist, expended on them, they would amply repay the labour of the cultivator.

BOTANICAL STRUCTURES.

Under this denomination are included those glazed structures dedicated to the cultivation of exotic plants and the production of tropical fruits, which are now generally regarded as indispensable appendages of the flower garden. The former has been in use in this country for nearly two centuries; but the latter is comparatively of recent introduction. The earliest notice we have of either is given by Plato in his Phædon; and after him, Columella speaks of similar structures, as used in Italy in his day, for the cultivation of the plants and trees of India and Arabia. In Seneca we have a description of the application of hot water as a means of securing the necessary temperature. The earliest plant-houses in the north of Europe were those of the botanist Jungerman at Altorf in Saxony; while those of Loader, a London merchant, and the conservatory in the Apothecaries' Botanic Garden at Chelsea, may be noticed as the first structures of the kind in Britain.

The construction of these, however, was ill adapted to the end in view, as they consisted of little else than a huge chamber of masonry, having large windows in front, and the roof was invariably opaque. The next step was taken, when it became fashionable to have conservatories attached to mansions, instead of having them in the *wilderness*, as the pleasure grounds were then denominated. This arrangement brought them within the province of the house-architects, and for nearly a century, utility and fitness for the cultivation of plants was sacrificed, as it is in many cases still, to the unity of architectural expression between the conservatory and the mansion. In other words, the conservatory was made an appendage to the house, and so disguised by massive architectural details, as to form merely a part of it. The admission of light, which is the principal element in plant culture, was completely disregarded, and is so still, when the construction of such houses is extended to those who are destitute of a knowledge of the laws of vegetable physiology.

Garden architecture has now, however, undergone a complete revolution, and such structures are now erected on principles of their own, elegance of design being invariably combined with utility or practical fitness for the purpose of their erection. For this we are mainly indebted to the late Sir George M'Kenzie, and to Messrs T. A. Knight and Loudon, who directed their practical and theoretical skill to details of this subject. The abolition of the duty on glass has greatly aided in carrying out those views, and the improvement in that material has left us little more to wish for. Without going into the details of recent changes, we may briefly state that the smallest extent of opaque surface consistent with stability, and the largest extent of glass, and that of the best quality, are the principal things to be aimed at in such erections. To attain these ends, the early improvers of hothouse architecture dispensed with massive wooden rafters, and expensive framed sashes, and for the most part, with the costly and useless masses of back-walls. In their zeal, however, they unfortunately fell into an opposite error by the employment of metallic substances instead of timber for their roofs. With a greater amount of light thus secured, the conducting power of metal caused a great irregularity of temperature, which it was found difficult to control; and notwithstanding the great elegance of metallic houses, this circumstance, together with their greater cost, and it is feared their limited durability, has induced most recent authorities to give the preference to wood. The combination of the two, however, as in the Crystal Palace of 1851, and more recently in that at Sydenham, shews clearly that, without much variation of heat or loss of light, spaces to any extent may be covered, and houses of any degree of altitude may be constructed.

The next improvement on the curvilinear structures of the authorities above quoted, was the ridge and furrow form, first suggested by the late Mr Loudon, but brought into use by Sir Joseph Paxton. This form, besides presenting better angles to the sun's rays than the antiquated lean-to buildings, has the advantage of being capable of extension to an indefinite extent without side-walls, whereas the other could not be extended in breadth beyond twenty or thirty feet, and even then involved the construction of a back-wall of corresponding height, which often cost as much as the half of the rest of the structure. The span-roof is a modification of the ridge and furrow style, and adapted to small as well as large houses. Figs. 30 and 32 are cross-sections of this style in its simplest form. It is now extremely popular, not only for greenhouses and conservatories, but for fruit-producing houses also. In these it will be observed the superstructure stands on a basement or parapet only two feet and a half in height, and is broken up into panels, better seen in fig. 47, into which glass ventilators are placed for the supply of fresh air, as near the floor of the house as possible, thereby avoiding the evils of cold draughts of frosty or cold dry air blowing in upon the tender foliage. The escape of heated and impure air is through the lanthorn ventilation along the apex of the ridge, the whole of the rest of the structure being a fixture.

When such forms are used as greenhouses, and it is universally admitted that it is the best form for such a purpose, the plants are set on a centre stage or stages, and along the sides, as shewn in the cross-section of the conservatory, fig. 46. When it is desirable to have a perspective view along the centre of the house, the side stages are increased in breadth, leaving an open passage down the middle.

Fig. 44 exhibits a greenhouse upon the old or lean-to principle, the plants being set on a stage reclining towards the back of the house. Plants so situated present only one side to the light, and hence soon become unsightly and one-sided, which no care on the part of the cultivator can remedy, short of turning them round once a day, and even that is attended with great labour and a small amount of benefit.

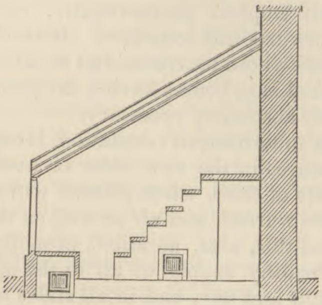

Fig. 44.

The conservatory may be, and often is, built in connection with the mansion, so as to be opened into from the drawing-room or boudoir. In many cases this arrangement has the defect of suffering from the shade of the building, and therefore, where circumstances will admit of it, it may be placed at a convenient distance from the house, and a connection formed by a glass corridor, so that a dry and comfortable communication may be at all times secured. It is also desirable that a conservatory connected with the mansion should be kept gay with flowering plants; and to accomplish this, the plants must be kept in a portable state, so that as they go out of bloom they may be removed to a subsidiary structure, and others brought in to replace them. Hence arises a vital objection to planting out flowers in beds of earth, as is so often done. There are also other objections to this, of a strictly cultural nature.

Conservatories are often with great propriety placed in the flower garden. Fig. 45 is offered as an example of this arrangement, and shews a conservatory constructed for Lord Overstone, in Northamptonshire, under the superintendence of Mr M'Intosh. Fig. 46 is a cross-section of the same. The plants are arranged in pots, placed on highly ornamental cast-iron stages, which occupy the centre, with a passage down the middle, and another crossing the house at right angles with the former, while a third passes round the centre stages, separating them from the elegant plant tables of elaborate casting, which surround the sides and ends of the house. Fig. 45 shews the structure placed upon an elevated terrace, and forming the termination of a long and spacious gravel walk. The basement is of highly polished Yorkshire ashler, richly moulded, panelled, and piered. Within the panels are placed plate-glass ventilators, opening three feet by twelve inches each, and extending all round the structure. The upright sides of the superstructure are constructed of open pilasters filled with plate-glass, one-fourth of an inch in thickness, and eighteen inches in breadth. The fan lights above, which are also moveable for extra ventilation during very warm weather, and the whole of the spaces between the pilasters, is glazed with the same material.

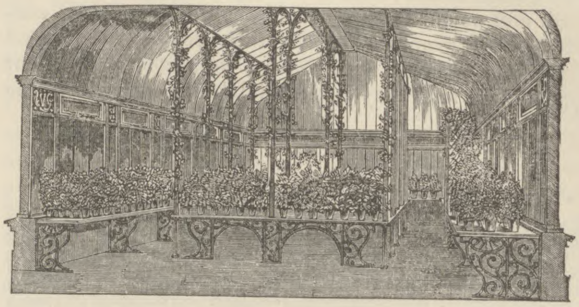

Fig. 46.

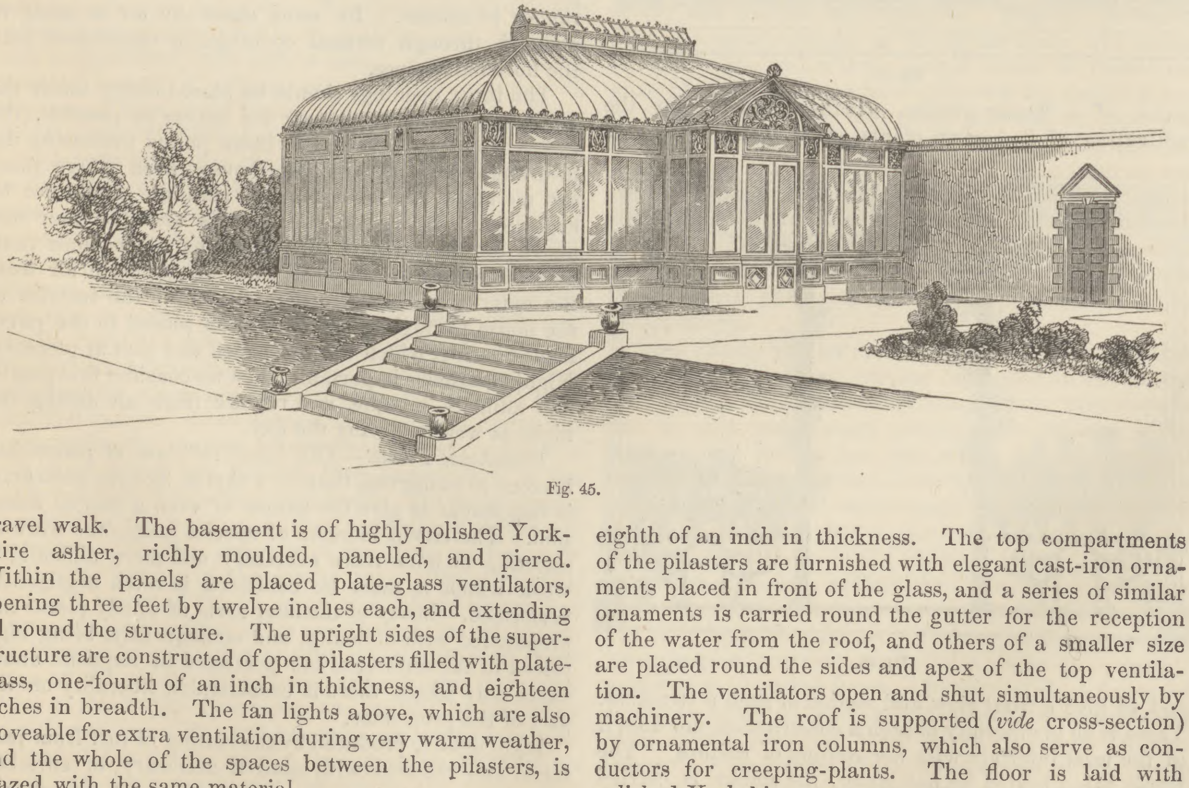

Fig. 45.

The roof is covered with Hartley's patent glass, one-eighth of an inch in thickness. The top compartments of the pilasters are furnished with elegant cast-iron ornaments placed in front of the glass, and a series of similar ornaments is carried round the gutter for the reception of the water from the roof, and others of a smaller size are placed round the sides and apex of the top ventilation. The ventilators open and shut simultaneously by machinery. The roof is supported (*vide* cross-section) by ornamental iron columns, which also serve as conductors for creeping-plants. The floor is laid with polished Yorkshire pavement, and is twelve inches above the level of the terrace walk, admitting of three steps at

Botanical Structures.

the entrance porch. The astragals of the roof are supported by a bar of T or angle iron, which goes round the house, and to it is connected the ornamental upright columns and the arches which spring from them. The columns are anchored to large stones placed below the pavement-floor, thus tying down the roof and supporting it at the same time.

Glass-houses, in any of the forms we have referred to, are infinitely superior to the old shed-looking forms, which have scarcely a redeeming quality. The former are cheaper in construction, in proportion to the accommodation they afford, better adapted to all the purposes of culture, and more elegant in appearance. Ranges of span-roofed houses, having their end or gables facing the south and north, and connected together by a glass corridor either running through their centres, or placed along their northern ends, have a connected and elegant appearance, and may appropriately be placed in the centre of a flower garden, whether intended for the cultivation of flowering plants or of fruits. Figs. 47 and 48 give a front view and section of such a structure. There is no incongruity in such a construction, nor does it in the least interfere with the routine of culture. The whole being heated by hot water, the smoke is carried away in an underground tunnel beyond the precincts of the garden, and the stoke holes, with the coals and ashes, are placed in vaults under ground. Such a range should be placed on an elevated terrace, from two or three feet above the surrounding ground line, and have a broad terrace walk and narrow flower parterre occupying the space between the houses and the extreme parapet wall.

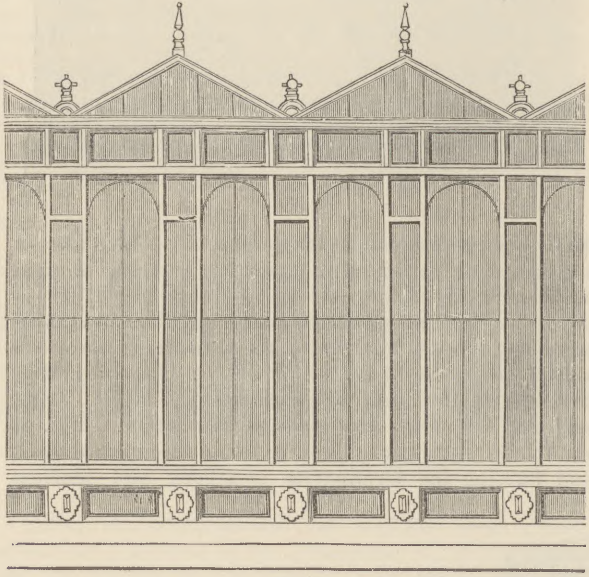

Fig. 47.

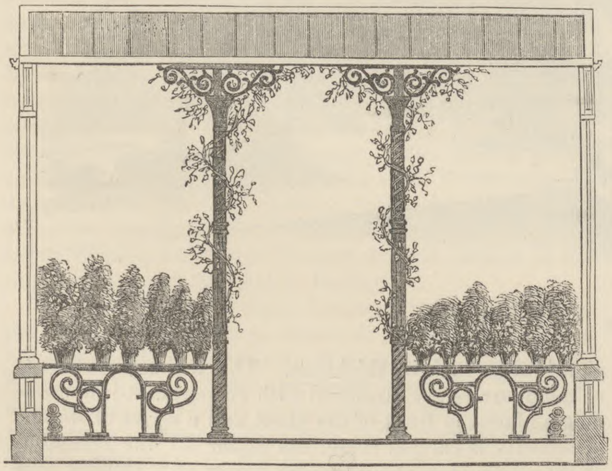

Fig. 48.

Green-house Plants.

The *Plant Stove* differs in no respect from those we have alluded to, except in having a greater extent of hot water pipes for the purpose of securing a greater degree of heat, which tropical plants require, compared with those from extra tropical countries. Indeed, to grow to perfection plants whose native habitat is under the brightness of a tropical sun, houses having the greatest amount of light become absolutely necessary.

Aëration, or subterranean ventilation, is one of the most important features in the new order of hothouse building. The roots of trees, when planted within our glass-houses, require warmth and air as well as the leaves and buds. Beyond this, also, aëration, properly conducted, brings in a healthy supply of air to the atmosphere of the house, night and day, and in all states of the external temperature. This is effected either by vaulting under the borders, or by laying down a system of four-inch drain-tiles, four feet apart, level with the foundations, and covering them, to the depth of eighteen inches, with rubble-stones, brick-bats, flints, &c., and upon these forming the soil borders. These vaults, or air-drains, have a connection with the external air, which, entering them, will diffuse itself through the drains or open joints of the pavement, and thus reach the roots. Vertical openings are also made upwards through the borders, to cause an *in-draught* of atmospheric air into the house, and air so procured has the advantage of being modified in temperature, and charged with humidity during its passage from the external orifice, and thus being in a state of all others the most beneficial to vegetation. The orifices of such air-drains are usually placed in the terrace wall which encloses the gravel walk and parterres, and which should in all cases surround such ranges of houses. In some cases the air is made to descend through vertical openings in connection with the horizontal pipes.

The inner openings should be placed either under the hot water pipes, or as near the boilers as possible, the difference of temperature at these points increasing the in-draught current. In plant-houses, even where there are no borders, this system of aëration should not be neglected. In fig. 45 the floor is elevated four feet above the foundations, thus affording a capacious vault beneath, which is supplied with atmospheric air from the exterior. This air is admitted into the interior of the house through brass ventilators placed in the pavement-flooring, which can be opened and shut at pleasure. Night aëration is important, when we consider that plants, like animals, breathe, and require fresh air during the night as well as during the day.

Greenhouse Plants.—This beautiful class of plants has become so numerous, that, in a sketch like the present, it is impossible to give the names of even a limited selection. The recent increase of species makes the work of selection at once more necessary and more difficult; a work which it must be confessed is often negligently performed. Many of the finer sorts of woody plants are propagated with difficulty, and consequently, being high priced in the nurseries, are possessed in requisite abundance only where there is considerable liberality on the part of the proprietor.

Light mould, produced by the rotting of turf from pastures, and reduced with sand if necessary, or enriched with leaf-mould, is well adapted for most greenhouse plants. Some require a mixture of peat earth; others

Green-house Plants.

thrive only in pure sandy peat. The common mode of propagation is by cuttings inserted in earth or sand, and covered, if necessary, with bell-glasses. A few sorts are increased by grafting or layers. Nearly all may be raised from seed, large quantities of which are annually imported from abroad; and, it may be added, many greenhouse plants ripen their seed in this country.

Many of these plants require shifting and fresh earth twice a year; all of them should be repotted once a year at least. It is the common practice to examine their roots in spring or the early part of summer, and, uncoiling or loosening the matted fibres, to put them into larger pots if necessary. As room is extremely valuable in limited greenhouses, it is desirable that the plants should be kept of a moderate size; and they are, therefore, rather to be under-potted than otherwise. Many of the free-growing plants require to be shifted again in August; at which period of the year it is considered preferable to repot those which require to be disturbed only once a year. During the summer months, a great proportion of the inmates of the greenhouse are placed in the open air, on a spot paved or laid with ashes, to prevent the entrance of earth-worms into the pots, and not too much exposed to winds. Meanwhile, their place in the greenhouse is occupied by balsams and other tender annuals of a showy character. On the approach of winter the plants are again placed under cover. All that is necessary in the management of the greenhouse in winter, is to keep up a steady but very moderate temperature, to preclude the access of damp by regular airing in mild dry weather, and to attend to moderate watering where it may be needed.

Of late years, particular genera of plants have come greatly into vogue, and it would be an omission not to notice some of them. Among the foremost may be mentioned the Pelargonium, with its affinities. This beautiful tribe has varied nearly as rapidly as the Dahlia; to the discomposure of some botanists, whose scientific logic has been brought into jeopardy. Pelargoniums are of easy culture, propagating readily by cuttings, and requiring only to be shifted from time to time. Equal to these in point of beauty of colour, and certainly superior in elegance of form, is the family of Cape heaths, the *Ericæ* of botanists. Of this genus there is said to be 600 species, considerably more than the half of which exist in our collections, and a very great number of hybrids have been raised in Britain, many of which are superior in beauty to the original parents. Many heaths may be raised from seed, which occasionally ripens in this country: the most common mode of propagation, however, is by cuttings, and this in some species is attended with difficulty. Heaths require a peaty soil, and attention in watering. For further information, we may refer to the excellent little treatise of the late Mr M‘Nab of the Botanic Garden, Edinburgh, whose success in this department was quite unrivalled, and in whose hands heaths attained a splendour which, we believe, they never reach in the environs of the Table Mountain itself. The superb genus Camellia is the only other that particularly claims our attention. To the elegance of the finest evergreen it unites the beauty of the fairest rose. The Camellia, though a native of Japan, is not particularly tender, but from some peculiarities in its constitution, its culture requires a considerable degree of attention and care. Cuttings of the single red variety strike freely, and upon these as stocks, the finer sorts are grafted by inarching or side-grafting. The soil generally employed is a mixture of peat and light loam. Care must be taken not to allow the roots to become matted in the pots. The young plants should be shifted at least once a year; when old, and in large tubs, once in two years will be sufficient. It is found beneficial to apply a certain degree of heat while the plants are growing, and till they form flower-buds for the following season. To have Camellias in perfection, a house with a span roof should be appropriated for their reception. There are some splendid collections of this noble plant in the nursery-gardens in the neighbourhood of London, and also in private gardens.

Conservatory and Stove Plants.

Conservatory Plants.—These are composed of a selection from the numerous inmates of the greenhouse. They should be naturally of an elegant form, capable in general of sustaining themselves, and somewhat hardy in their constitution. Many of the Australian plants, particularly the genera Acacia, Banksia, Dryandra, Chorozema, Corræa, Daviesia, Dillwynia, Epacris, Eutaxia, Gastrolobium, Goodia, Gompholobium, Hovea, &c., are well adapted for this purpose. The ascending Proteas of the Cape, and many others of a similar habit, may likewise take their place in this department. To these may be added a few of the hardier Heaths and Camellias, together with Azaleas from Japan, double-flowering Pomegranate, Camphor-laurel, Tea-tree, and some of the varieties of the magnificent and consecrated Rhododendron arboreum. Such climbing plants as Lonicera flexuosa, Passiflora, Cantua, Bignonia, Kennedya, Mandevilla suaveolens, Zichya, Tacsonia, and the trailing Pelargonium. In the management of the conservatory, abundant air should be admitted, and care should be taken not to *draw* the plants; that is, not to cause them to become too tall and spindle-formed by over-crowding. They should be so pruned as to keep them comparatively short and bushy; but after all pains have been taken, the sorrowful time at length arrives, when they either disfigure themselves by pressing against the glass, or must submit to the no less distorting process of a violent amputation. To meet such exigencies, it is recommended that, wherever there is also a greenhouse, a few plants should be kept in training for the conservatory, and substituted in the room of any that become unmanageable. After all, the fourth, fifth, and sixth summers of the conservatory will always be the finest; and when a longer series of years have gone by, and the plants have outgrown the space allotted to them, perhaps the best thing that can be done is to change the whole interior of the house, plants and all. If this operation be anticipated, and for a year or two prepared for, sufficiently large plants may be had in readiness, and the appearance of a well-furnished house be attained in one or two seasons. It is scarcely needful to add, that the neatness which is so desirable everywhere in the flower garden is absolutely indispensable in the conservatory.

Stove Plants.—There are many beautiful plants, natives of tropical regions, which are cultivated in our stoves, but which, from the elevated temperature they require, can be only occasionally visited with pleasure. This may account for the fact that stoves are seldom found except in first-rate gardens, even where the price of fuel is inconsiderable. It is unnecessary to be minute respecting their culture, which is precisely that of greenhouse plants, differing only in the degree of heat. Many stove plants are succulent, such as the Cactus, Aloe, and their congeners, and of course require an arid soil, composed of a little light loam mixed with lime-rubbish or shivers. The compost generally employed consists of 1 part of rotted dung, 1 rotted leaves, 1 heath mould, 1½ loam, and 1 coarse sand, all well mixed together; and the pot filled nearly one-third with shreds, so as to form an effectual drain. Some of the species, such as the Cactus speciosus and Cereus flagelliformis, are improved and made to flower more freely by being kept growing vigorously in the greenhouse during summer, and also by being grafted on the stronger growing species of the same genera. Stove plants thrive best in the tepid vapour peculiar to the equatorial climes. In order to furnish bottom-heat, a pit is prepared in form of a vault, through which hot water is made to circulate in pipes. Over this a bed of small stones or gravel is laid, and in it the pots are plunged, or set on the surface, according to circumstances. On the front shelves are occasionally placed the smaller and younger plants, that part being most accessible to light and air. Small cisterns too are introduced to contain tender aquatics. Along the roof some of the more elegant species of Passiflora, such as P. quadrangularis, may be trained; and through the branches of some of the woody plants, Cuscuta, Combretum, Quisqualis, and other tender climbers, may be allowed to twine themselves. In the pit may be plunged some of the Palms, those princes of plants. In short, there is no end of those numerous tribes, "the potent sons of moisture and of heat," with which the teeming regions of the equator are filled; and no suit of stoves in this country, however extensive, can come up to the wishes of the botanist. The management of this department of floriculture is laborious and trying to the constitution. A strong heat, both in the pit and in the atmosphere, must be maintained; the air must be kept charged with vapour, and the plants require frequent shifting and repotting. To these, if space allowed it, we ought to speak of such structures as are devoted to the cultivation of Orchids, the Camellia, the Geranium, Succulent-plants, and others, as well as of pits in which young plants are nursed and brought forward.

CALENDAR.

January.

Kitchen Garden.—Sow early frame and other early peas in the beginning of the month, and dwarf marrowfats about the end of the month; early mazagan and longpod beans during the first and last weeks; onions on very light soils; as also parsley, if not done in August, on a warm border; short-topped radish in two or three sowings, at a week's interval, in the same situation. In the last fortnight sow hardy green and brown Dutch lettuce.

Plant fruit-trees, if not done in autumn, which is the proper season, in open weather, mulching over the roots to protect them from the drought which may occur in spring. Plant shallot.

Prune all sorts of fruit-trees in mild weather or in moderate frosts, nailing only in fine weather; wash those trees infested with insects, with soap-suds and flowers of sulphur, and tobacco liquor.[1]

Forcing Department.—Prepare for making up hotbeds for early cucumbers and melons, at least where pits heated with hot water is not in use. Sow salads, carrots, and kidney-beans on slight hotbeds. Sow peas in cold frames for transplanting. Force asparagus, sea-kale, and rhubarb, in hotbeds, in pits, in the mushroom-house, or in the open garden by covers surrounded with litter. Give air in fine weather, and water sparingly, in the pinery and cucumber-pit, and to other forcing-houses, according to the progress of the trees. Attend to the forced kidney-beans and strawberries. Give abundance of air to the greenhouse, conservatory, and alpine frame, but little water. Begin to force roses, kalmias, rhododendrons, &c., and hardy flowers and bulbs.

Flower Garden.—Plant dried tubers and bulbs of bordered flowers, if not done in autumn; but roots of the finer florists' flowers ought to be deferred till next month.

Transplant herbaceous plants in light soils, if not done in autumn; also deciduous trees, shrubs, and hedges. Lay edgings in fine weather.

Sow mignonette, stocks, &c., in pots; sow sweet peas, and a few hardy annuals, on a warm border. Give stage auriculas and carnations abundance of air; but keep them rather dry, to prevent damping off.

February.

Kitchen Garden.—Sow beans and peas in the beginning and end of the month; a few early cabbages, to replace the last sowing in August; red cabbages and savoys in the last week. Sow also early horn carrot; Dutch turnip; onions for a full crop in light soils, with a few leeks. Sow chervil and fennel, and lettuce for succession, with radishes and round-leaved spinach, twice in the course of the month; small salads every fortnight.

Plant Jerusalem artichokes, garlic, horse-radish, and early potatoes. Strawberries may be planted about the end of the month. Transplant for seed, if not done before, all the brassica tribe, including cabbage, cauliflower, turnip, &c.; also carrots, onions, beet, celery, endive, leeks, and parsnips. Transplant to the bottom of a south wall a few of the peas sown in November for the first crop.

Prune apricots, peaches, nectarines, and plums, before the buds be much swelled; also apples, pears, cherries, gooseberries, currants, and raspberries, before the end of the month. Finish the dressing of vines, keep the fruit-room free from spoiled fruit, and shut it close.

Forcing Department.—Plant out melons and cucumbers on hotbeds and in pits, sowing more for succession. Sow carrots, turnips, and early celery; cauliflower, to be afterwards planted out. Plant early potatoes on slight hotbeds. Continue the forcing of asparagus, rhubarb, and sea-kale. Pine-apple plants require little water at this season; young plants in dung-frames ought to be kept free from damp. Shift fruiting plants by the middle of the month, if not done in August. Continue the forcing of all sorts of fruits. Those who have not commenced sooner will find this one of the best seasons to begin. Be careful to protect the stems of vines that are outside of the forcing houses.

Let the greenhouse and conservatory have plenty of air in mild weather. Put in an extra quantity, if not done in autumn, of cuttings of Pelargoniums, Fuchsias, Calceolarias, Heliotropes, and Salvias, &c., for the flower garden. Sow stocks, a few tender annuals, and dahlia seed, on a slight hotbed, or in pots.

Flower Garden.—In good weather plant dried roots, including most of the finer florists' flowers; continue the transplanting of hardy biennial flowers, and herbaceous plants.

Sow in the last week mignonette, and hardy annuals, in a warm border, for subsequent transplanting.

March.

Kitchen Garden.—Sow main crops of peas, beans, cabbages, onions, leeks, carrots, parsnips, Brussels sprouts, borecoles, lettuces, and spinach. In the beginning, and also in the end of the month, sow turnips and savoys. In the last fortnight sow asparagus, cauliflower, sea-kale, cardoons, celery, and most of the culinary aromatics, as dill, fennel, parsley. Small salads should be sown every ten days.

Plant early potatoes in the first week, and a main crop during the last fortnight. Jerusalem artichokes, sea-kale, asparagus, and peas, raised in frames, may now be planted. Full crops of cabbages should now be planted out, and cauliflowers under hand-glasses. Propagate by slips the various pot-herbs, as mint, sage, savoy, tansy, &c.

Fruit Garden.—Finish the pruning of fruit-trees before the middle of the month. Protect those coming into blossom. Begin grafting in the third week; dig and dress between the rows of gooseberries, currants, and other fruit-trees, if not already done. Kill wasps when they first appear, for the death of every individual now is equal to the destruction of a colony in autumn.

Forcing Garden.—Proceed with the forcing of melons and cucumbers, giving air, and maintaining the proper temperatures. Examine pine-suckers and crowns, potting those that are kept in tan during winter; repotting those that require large pots, and dressing the roots of such as are sickly; about the middle of the month, shift to the succession pit, and give a top-dressing to the fruiting plants; turn the tan, and add new bark to the pits, to keep up bottom-heat, where such is used. In the vinery and peach-house, attend to the keeping down of insects by watering; and promote the growth of the young shoots, by gentle steaming in the evenings. Sow the seeds of capsicum and tomato.

Greenhouse.—More water may be given than formerly. Sow seeds of greenhouse and hothouse plants; also the different sorts of tender annuals; pot off those sown last month; shift greenhouse and stove plants; plant tuberoses in pots for forcing. Begin to propagate greenhouse plants by cuttings.

---

[1] We have deemed it unnecessary to treat separately, or at length, of the means of destroying insects; many of the nostrums recommended proving very inefficient. The wash here mentioned is perhaps the best and simplest for the stems and branches of wall fruit-trees. Some prefer making it of the consistence of paint, and laying it on with a brush. One advice we would tender to all gardeners,—not to be anxious to kill the smaller kinds of the feathered songsters, the soft-billed warblers of the garden, which are often suspected of attacking blossom or fruit, when they are only picking off caterpillars or aphides, their favourite food. In hothouses, the keeping of the walls and frame-work clean, by frequent white-washing and painting, is very important; and much benefit results from occasionally filling them with the smoke of tobacco paper, and then thoroughly syringing.

Flower Garden and Shrubbery.—In the last week, sow hardy annuals in the borders, with biennials that flower the first season; as also perennials. Plant anemone and ranunculus roots. Transplant from the nursery to their final sites annuals sown in autumn, with biennials and herbaceous plants. Propagate perennials from root-slips and offsets. Protect tulips, hyacinths, and choice flowers, from severe weather. In the first week put into heat the finer sorts of dahlias, so as to spring them, and prepare them for propagation by cuttings and by division of the roots. Likewise finish the pruning of all deciduous trees and hedges as soon as possible. Attend to the dressing of shrubberies, laying of turf-edgings, and to the state of gravel walks.

April.

Kitchen Garden.—Sow asparagus, sea-kale, beet, salsify, scorzonera, skirret, carrots, and onions on heavy soils; also peas, beans, turnips, spinach, celery, cabbages, savoys, and German greens, for succession. Sow broccoli and kidney-beans both in the second and in the last week; and small salads should be sown twice or thrice during the month; also all sweet herbs, if not done last month.

Plant cauliflower, cabbages, sea-kale, lettuce; and finish the planting of the main crops of potatoes. Propagate all sorts of pot-herbs, and attend to the hoeing and thinning of spinach, onions, turnips, &c. Earth up cabbages, cauliflower, peas, beans, and early potatoes. Stake up peas; blanch sea-kale and rhubarb in the open air, by covering with straw or leaves.

Fruit-Trees.—No pruning ought to be left undone till this period; stone fruits, in particular, are much injured by spring pruning. If vines have been neglected, rubbing off the buds that are not wanted is safer than pruning. Protect the finer sorts of fruit-trees on the walls.

Forcing.—Continue the preparation of succession beds and pits for cucumbers and melons. Sow gourds and basil. Pot love-apples and capsicums. Attend to the routine culture of the pinery, giving water and air when necessary. In the forcing-houses, from the variable state of the weather, considerable vigilance is required in giving air. Keep down red spider (acarus) in the more advanced houses by frequent syringings. Continue the usual operations of disbudding and thinning of fruit, and take care to keep up the proper temperatures.

Greenhouse.—Still sow all sorts of tender annuals. Proceed with all necessary shiftings. Propagate rare and fine plants by cuttings or grafting. Pot off tender annuals, and cuttings of half-hardy greenhouse plants put in in February for the use of the flower garden.

Flower Garden and Shrubbery.—Sow main or succession crops of annuals of all sorts; half-hardy annuals in warm borders, or on slight hotbeds. Biennials and perennials should be sown before the middle of the month. Plant Tigridia pavonia and fine stocks. Finish the transplanting of herbaceous plants by the end of the first week. Protect stage auriculas and hyacinths from extremes of every description of weather; and tulips from hoar-frosts and heavy rains. Plant out tender deciduous trees and shrubs raised in pots. Remove part of the coverings of all tender shrubs and plants in the first week, and the remainder at the end of the month. Form and repair lawns and grass walks, by laying turf and sowing perennial grass-seeds. Plant evergreens.

May.

Kitchen Garden.—Sow small salads every week; radishes and lettuces thrice; spinach once a fortnight; carrots and onions for late drawing; kidney-beans in the first week and last fortnight. Peas and beans, cauliflowers, cabbages, Brussels sprouts, borecole, broccoli, savoys, and German greens, for late crops. Sow pumpkins and cucumbers on a warm border in the last week. Continue the various operations of hoeing and earthing up the different crops.

Fruit-Trees.—Disbud peaches, nectarines, and other early trees against the walls; also attend to the thinning of fruit. Give occasional washings with the engine to keep down insects. Pick caterpillars from gooseberries and wall trees on their first appearance. Mulch, if not done before, all newly planted fruit-trees, watering abundantly in dry weather. Remove from raspberries and strawberries all suckers and runners that are not wanted.

Forcing.—Plant melons, and cucumbers, and some basil, on the hotbeds prepared for vegetables in February, and now free. Plant out pumpkins on dung-ridges, under hand-glasses. Sow late crops of cucumbers and melons; attend to the various particulars in their culture, heat, air, water, shade, and insects. Go on with the usual culture of the pinery; give abundance of heat and water, keeping down all manner of insects.

Greenhouse.—Turn out hardy plants about the middle, and the more tender at the latter end of the month. Sow tender annuals for succession; potting and shifting those sown at an earlier period. Pot off likewise all rooted cuttings. Put in cuttings of the different desirable species which are now fit for that purpose. Sow a few hardy annuals and ten-week stock, &c., for late crops.

Flower Garden.—Sow annuals for succession; biennials in the last week, in the nursery compartment, for next year. Propagate by cuttings, dahlias, pansies, double wall-flowers, rockets, scarlet lychnis, and lobelias, by dividing the roots. Plant out, during the last week, dahlias, hardy pelargoniums, stocks, and calceolarias, protecting the dahlias from slight frosts. By the end of the month, masses of the following plants may be formed with safety in warm localities:—pelargonium, heliotropium, fuchsia, salpiglossis, nierembergia, salvia, verbena, bouvardia, and lobelia. Protect tulips, ranunculuses, and anemones, from the mid-day sun, from rains, and winds. Remove the coverings from all tender plants in the open air.

Shrubbery.—Transplant all kinds of evergreens this month and September, being the proper seasons. The rarer coniferæ should be planted now and in June, after they have commenced to grow. Proceed with the laying down of lawns and gravel-walks.

June.

Kitchen Garden.—Sow peas and beans for late crops. The kinds used for early crops are likewise best for this purpose. Sow salading every ten days; also carrots and onions for drawing young. In the beginning of the month sow endive for an early crop. In the first week sow turnips for succession; and in the third week for a full autumn crop. Scarlet and white runners for a late crop; cabbages for coleworts.

Plant full crops of broccoli, Brussels sprouts, savoys, German greens, and leeks; ridge out early celery, successional crops of cabbage and cauliflower. In the first fortnight of the month, plant cucumbers for pickling, in a warm border, placing hand-glasses over them. Pull and store winter onions, if ripe.

Fruit Trees.—Train and prune the summer shoots of all descriptions of wall and trellis trees. Standards do not require this, except those are trained *en pyramide* or *en quénouille*. Mulch and water fruit-trees and strawberries in dry weather, desisting from watering as soon as the fruit begins to ripen. Net over cherry-trees, to protect the fruit from birds. Destroy insects by frequent washings, and directing tobacco-smoke against them, or by strewing snuff (or the fine powder of tobacco) over them. In the first week, plant out love-apples in vacant spaces along the bottom of a south wall.

Forcing and Greenhouse Department. Hotbeds and Pits.—Proceed with planting melons and cucumbers raised from seeds and cuttings, for late crops. Keep up the necessary temperatures for ripening of the fruits. Continue the operations in the pinery stated under last month; but, if very large sized fruit be desired, remove the whole suckers from the stem and roots, and apply heat and water in abundance. Shift suckers and succession plants in the beginning and middle of the month, as the state of the plants may require.

Forcing-houses may have the same treatment as stated last month. Little water and abundance of air must be given to those houses where the fruit is beginning to ripen. Those in which the fruit is past, ought to be constantly under a system of thorough ventilation.

The *Greenhouse* will now be occupied with tender greenhouse plants and annuals, and the more hardy plants from the stove, for here they will remain longer in flower. Shift, re-pot, and propagate all plants, fine perennials, biennials, or annuals, and cuttings of all sorts that are desirable. Sow fragrant or showy annuals, to flower in pots during winter.

Flower Garden.—Take up bulbs and tuberous roots, and dry them in the shade before you remove them to the store-room. Fill up with annuals and greenhouse plants those beds from which the bulbs and roots have been raised. After this season, keep always a reserve of annuals in pots, or planted on beds of thin layers of fibrous matter, from which they are easily removed with balls, to fill up any blanks which may occur in the border or parterre. Sow perennials, if neglected last month, to be planted out in the spring. Lay and pipe carnations and pinks in the end of the month.

July.

Kitchen Garden.—In the first week, sow peas for the last crop of the season. In the last week, sow yellow turnip for a full winter crop, and spinach for an early winter supply. Endive, for autumn and winter use, in the beginning and end of the month; also successional crops of lettuce and small salads.

Plant full crops of celery, celeriac, endive, about the middle and end of the month; late crops of broccoli, cauliflower, and coleworts, in the last week. Gather and dry medical and pot herbs; also propagate such by slips and cuttings.

Fruit-Trees.—Continue the summer pruning and training of all wall and espalier-rail trees, with the destruction of insects. Plant strawberries in pots, for forcing next winter. Propagate different sorts of fine fruit-trees, by budding on other trees, or on prepared stocks.

Forcing.—Attend to the pruning of melons and cucumbers, giving air and water, and maintaining heat, &c. Go on with the usual cultivation of the pinery, but withhold water from the plants when the fruit begins to ripen. Have the old plants with suckers on them put into a brisk bottom-heat, giving proper supplies of water: this will increase their size very much, and materially shorten the period of their coming into fruit. The forcing-houses ought to have the same treatment as stated for last month.

In the *Greenhouse*, little alteration will take place in the culture and management from that given for last month; necessary attention being paid to potting, shifting, and putting in cuttings, and giving abundance of water to the potted plants, both in the house and out of doors.

Flower Garden and Shrubbery.—Take up the remainder of tuberous roots, such as anemone, ranunculus, &c., finishing by the end of the first week; fill up their places, and any vacancies that may have occurred, with annuals from the reserve ground. Propagate herbaceous and other plants that have gone out of flower, by means of cuttings and slips; also roses and American shrubs, by laying, budding, or cuttings. Go on with the laying and piping of carnations and pinks; attend to the staking and tying up of dahlias and strong herbaceous plants.

August.

In the *Kitchen Garden*, sow winter and spring spinach in the beginning and about the end of the month; parsley and winter onions, for a full crop, in the first week; cabbages, cauliflower, savoys, and German greens, about the middle of the month, for planting out in spring; lettuce in the first and last week; small salads occasionally; black, Spanish, red and white queen radish, for winter crops.

Plant and earth up celery and endive. A few coleworts may still be planted.

In the *Fruit Garden*, proceed in the training and regulation of summer shoots of all fruit-trees as directed for the three last months. Net up, in dry weather, gooseberry and currant bushes, to preserve the fruit till late in the autumn. Every exertion must now be used by the gardener to preserve the ripening fruits on the walls from insects, and to destroy wasp nests.

Forcing.—The same routine of cultivation in hotbeds and pits may be proceeded in as stated for last month. Sow, and propagate by cuttings, in the beginning of the month, cucumbers, to be afterwards grown in hot water pits, or in boxes in the front of the pinestove, for a winter crop. In the pinery most of the fruit will be cut by the middle of the month, when a general shifting of succession plants will take place; as also a potting of suckers; but these will be strengthened by being allowed to remain on the old plants until the end of this month. In the forcing-houses where the crops are past, part of the sashes may be removed, so as to permit thorough ventilation.

Greenhouse.—Attend to the propagation of all sorts of greenhouse plants by cuttings, and to the replacing in the greenhouse and stoves the more tender species, by the end of the month in ordinary seasons, but in wet weather in the second week. Sow half-hardy annuals, as Clarkia, Schizanthus, Coreopsis, &c., to flower during winter.

Flower Garden and Shrubbery.—Sow in the second and the last week, on a warm border of a light sandy soil, with an east aspect, for planting in spring, Clarkia pulchella and elegans, Coreopsis tinctorea, Œnothera Lindleyana and roseo-alba, Collinsia grandiflora, Schizanthus pinnatus, &c. Auricula and Primula seeds in pots and boxes. Propagate all sorts of herbaceous plants by rooted slips; lay chrysanthemums; take off layers of carnations, pinks, and pansies. Transplant evergreens in moist weather, about the end of the month: and propagate them by layers and cuttings.

September.

Garden.—Sow a few small salads for late crops; lettuce and spinach, if not done last month, for spring crops. Plant endive and lettuce. If broccoli be too strong or tall to withstand the winter, lift them and lay them nearly up to the neck in the earth. Lift onions, and lay them out to win on a dry border or gravel walk. Lift potatoes and store them.

Fruit-Trees, &c.—Finish the summer pruning and training. Assist the maturing of the fruit, and, what is equally important, the ripening of the young wood for next year, of peaches and nectarines on hot walls, with fires during the day. Gather and lay up in the fruit-room with care the autumnal sorts of apples and pears. Plant strawberries for a main crop.

Forcing.—Take care that late crops of melons and cucumbers be not injured by damping, from getting too much water and too little air. In the pinery the usual routine of cultivation may be carried on; in the first week take off and pot all strong suckers, if not done in the middle of last month; the remainder may be taken off at the end of the month, and planted in old tan in a frame or pit prepared for that purpose. In this way they will be found to keep much better over the winter, and to be better supplied with roots than if they had been potted, which ought never to be done after this season. Expel damp, and assist the ripening of late crops of grapes and peaches, with fires during the day. Prune early vines and peaches.

Flower Garden, &c.—Sow in the beginning of this month all half-hardy annuals stated for last month, if not done at that time. Sow also the different species of primula; and the seeds of all such plants as, if sown in spring, seldom come up the same season, but if sown in September and October, vegetate readily the succeeding spring. Continue the propagation of herbaceous plants, taking off the layers of carnations, pinks, pansies, and chrysanthemums, by the end of the month. Plant evergreens; lay and put in cuttings of most of the hard-wooded sorts of shrubby plants.

October.

Kitchen Garden.—Sow small salads and radishes in the first week; mazagan beans and early frame peas in the last week. If the winter prove mild they will be somewhat earlier than those sown next month or in January.

Plant cabbages in beds or close rows till wanted in spring. Cauliflowers in the last week, to receive the protection of frames, or, at any rate, at the bottom of a high wall or hedge in a sheltered situation.

Store potatoes, beet, salsify, scorzonera, skirret, carrots, parsnips, by the end of the month.

Fruit Garden.—Such fruit-trees as have dropped their leaves may be transplanted, for which this is the best season, whether the leaves have fallen or not. Protect fig-trees, if the weather prove frosty, as soon as they have cast their leaves. Cover late crops of grapes on hot walls with woollen nets or mats, to prevent injury from frost. Store and lay up very carefully during the month all sorts of apples and pears, the longest keeping sorts not before the end of the month, if the weather be mild. A part of them may be placed in a close cellar.

Forcing.—Assist hotbeds and pits with fresh linings, to keep up the declining heat of such beds as have not ripened off their crops. Give abundance of air in good weather. Gradually lower the heat of the pinery.

Dress vines and peaches; clean and repair the forcing houses and their flues.

Greenhouse.—Replace all sorts of greenhouse plants. Fill the pits with pots of stocks, mignonette, and hardy annuals for planting out in spring, along with many of the hardy sorts of greenhouse plants. The whole ought to be thoroughly ventilated, except in frosty weather. Begin to force roses, hyacinths, and a few other bulbs, for winter and early spring decoration.

Flower Garden.—Sow a few pots of hardy annuals in a frame, or on a sheltered border, for spring use, as directed for August.

Plant the greater part of the common border bulbs about the end of the month, with a few anemones for early flowering. Transplant strong plants of biennials and perennials to their final situations.

Protect alpine plants, stage auriculas, and carnations, with glass frames; half-hardy greenhouse plants, such as fuchsias, &c., about the end of the month, with coverings of broom or spruce-fir, preferring the latter. Take up, dry, and store dahlias and all tender tubers in the end of the month; pot lobelias and similar half-hardy plants from the open borders.

Transplant all sorts of hardy evergreens and shrubs, especially in dry soils, giving abundance of water. Put in cuttings of all sorts of evergreens, &c.

November.

Kitchen Garden.—Sow early frame peas and mazagan beans, in the second week, for an early crop. Protect endive, celery, artichoke, sea-kale, with stable-litter or ferns; mulch asparagus with hotbed dung; take up endive, late cauliflower, early broccoli, and lettuces, and lay them in an open shed, or in old cucumber and melon pits, which will protect them from frost, and afford a supply during winter. But pits constructed for the express purpose are much better. They should be placed behind a north wall. Force rhubarb and sea-kale in the open border, under boxes or cases, surrounded and covered with well-fermented stable dung. Plant all sorts of fruit-trees in fine weather—the earlier in the month the better. Commence and carry on the various operations of pruning and nailing when the weather may permit. Take off such late sorts of apples and pears as may remain on the trees, and lay them carefully past in the fruit-room; which place will require frequent examination, and the removal of all decayed fruit.

Forcing and Greenhouse.—In hotbeds and pits keep up the requisite degree of heat. Cucumbers and pines, on hotbeds, will require more than ordinary attention, to prevent them damping off from too much moisture. Where a circulation of hot water in pipes is employed for heating, the necessary temperature and dryness are much more under the control of the gardener. Force asparagus, rhubarb, and sea-kale, in the mushroom-house or pits.

In the forcing-houses prune and train the trees; fork over and dress the borders of such houses as have not been already done. Continue the forcing of roses, hyacinths, &c. The directions for the greenhouse and conservatory in January apply also to this month generally.

Flower Garden, &c.—Plant dried tubers of border flowers, but the finer sorts had better be deferred till spring. Protect such half-hardy plants as were not sheltered last month. Plant deciduous trees and shrubs as long as the weather continues favourable, and before the soil has parted with the solar heat absorbed during summer. This is the reason why early autumn planting is so strongly recommended. Dig and dress such flower borders and shrubberies as may now be cleared of annuals and the stems of herbaceous plants.

December.

Kitchen and Fruit Garden.—Sow a few peas and beans, as in November. Very few operations can be carried on during this month, with the exception of trenching and digging in dry weather, operations which should by all means be attended to. The advantages of deep cultivation are now sufficiently acknowledged.

Plant all sorts of fruit-trees in mild weather. Proceed with pruning and nailing wall-trees, whenever an opportunity occurs. Examine the fruit-room every week, removing the fruit found in a state of decay.

Forcing, &c.—The same degree of attention to hotbeds and pits will be necessary as in the last month. Continue the forcing of asparagus, rhubarb, and sea-kale, in pits and in the mushroom-house.

Proceed with the usual routine of culture commenced last month, making the necessary preparations to begin forcing by the last week of this, or the first of next month.

Flower Garden, &c.—The directions for last month will be found equally applicable to this. Rake and sweep leaves from lawns and gravel-walks, repairing the latter as occasion may require.

(P. N.) (C. M'I.)

HOSANNA, a Hebrew word, meaning *Save, we pray.* At the Feast of Tabernacles the Jews carried branches of the palm and myrtle tree, repeating verses 25 and 26 of Psalm cxviii., which begins with Hosanna. The expression became a term of acclamation, and was applied to the prayers of the several days during which the feast lasted. The feast itself was called the Great Hosanna, and more specially the seventh day of the feast.

HOSEA, Book of, a canonical book of the Old Testament, occupying the first place among the twelve minor prophets in the Hebrew, Alexandrian, and Vulgate Scriptures. This position has been vindicated by some from the opening verse, in which are found the words, "The beginning of the word of the Lord;" but it is more probable that it was assigned to Hosea from the greater extent, and perhaps the peculiar national character, of his book. The tribe to which the author belonged has been matter of question. Maurer pleads for Judah, and—(1.) takes the case of Amos, as showing that a Jewish prophet might be sent to Israel; (2.) appeals to the mention by Hosea of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah, as showing that he regarded these as his sovereigns, and must therefore have belonged to Judah. It is replied (1.) by Credner, that the case of Amos is peculiar, and was regarded as such (*Amos* vii. 12), and cannot therefore be made the ground of an argument in the present case; and (2.) by Hengstenberg, that the separation of Israel from Judah during the theocracy could not have been regarded by the inspired prophet as anything but rebellion against the House of David, to whom the promises were made; that, accordingly, in the sight of God, Israel and Judah (the twelve tribes) were regarded as one religious confederation by Hosea, as they were by Elijah, when he took the *twelve* stones, one for each tribe; (3.) also, by Hengstenberg, that, in a chronological point of view, it was important to make the reference to the successors of Uzziah, because confusion existed at this time in the Israelitish chronology owing to interregna. The majority of commentators—such as Rosenmüller, De Wette, Eichhorn, Hengstenberg, and Uhland—adopt the opinion that Hosea was an Israelite. The probable period of his prophetical career has been made out as follows:—

During Uzziah's reign	26 years.
... Jotham's	16
... Ahaz's	16
... Hezekiah's	2
	60

Some, however (as Horsley), make the period longer; others (as Rosenmüller) make it shorter. The style of Hosea is abrupt, and often obscure; abounding in idiomatic and anomalous expressions and phraseology. His prophecies are mainly directed against Israel, whose history during his career was one dark tissue of robbery, assassination, and usurpation amongst the higher, and very general degradation amongst the lower ranks of the people. The command of God to the prophet to take to himself a wife of whoredoms, and beget children of whoredoms, has given rise to much difference of opinion:—(1.) Was it real? Cyril, Theodoret, Basil, Augustine, Grotius, Houbigant, Horsley, and Stuck, believed it to be so. (2.) Was it an allegory? It was so considered by the Chaldee paraphrast, Jerome, Drusius, Bauer, Rosenmüller, and South. Or, (3.) Was it a vision? So thought Maimonides, and some others. In any case, it is allowed that the transactions were of a typical character. Hengstenberg's explanation is substantially that the transactions are allegorical. The leading objection to the literal interpretation is, that the events must have spread over a period of several years, which would have been fatal to the impressiveness of the lessons intended to be taught.

HOSPITAL, Hospitale, in cloisters, the place of shelter for strangers, whether rich or poor; thus equivalent to our hotel, the *Xenodocheion* of the Greeks, the *Hospitium* of the Romans. The *hospitalia* of the Romans correspond with our inns. They were small erections on the right and left of the main house. In Greece, a person who had done any great public service might be rewarded with money and provisions, but he required to look after a place of abode himself. Bearing some resemblance to our present hospitals were the public buildings for the aged women of Delos, built on the island called Rhene; and those buildings which, at a later period, were erected near the temple of Æsculapius, for sick persons coming in search of health. It was possibly a similar institution which Antoninus built at Epidaurus. Another appears to have existed on the island of the Tiber at Rome, to which sick slaves were brought to be healed. *Bethesda* (house of mercy), with five porches, was a place in Jerusalem to which the sick were brought to await the moving of the waters. Also the *Taberna Meritorum* at Rome appears to have been an hospital for invalids.

Hospitals for the poor and sick are prominently characteristic of Christianity. So early as the Council of Nice, A.D. 325, they are spoken of as commonly known. The first celebrated hospital was that of Cæsarea, A.D. 370–380, richly endowed by the Emperor Valens. It was of immense dimensions. After it followed the hospital of Chrysostom, at Constantinople. In the ninth century there were 24 hospitals in Rome alone. A foundling hospital was first established at Milan, A.D. 787; a lazaretto about the same time in Constantinople; and an orphan hospital in the same city, A.D. 1090, by Alexius I.

Hospitals are now universally established in all parts of Christendom, and appropriated for all classes of the community, and for all kinds of diseases. The great hospitals of London, Edinburgh, Dublin, Paris, &c., are described under these towns respectively.

HOSPITALLERS, or Knights of Malta. See Knighthood, *Orders of*.

HOSPODAR, a title borne by the governors of Wallachia and Moldavia. Although nominated by the Porte, they possessed absolute power within their own dominions. Formerly they were chosen from the Greeks of Phanar, but lately they have been taken from amongst the native boyards or nobles. By the treaty of Adrianople in 1829, the Principalities were placed under Russian protection, and from that time till the treaty of Paris 1856, the Hospodars were virtually the nominees of Russia.

HOST, from *hostia*, a victim offered in sacrifice. In the service of the Church of Rome, the consecrated wafer is called the host. See Sacrifice.

HOTTENTOTS. See Africa.

HOTTINGER, Johann Heinrich, an eminent Swiss orientalist and biblical scholar, was born at Zurich in 1620. At the gymnasium of his native town, he distinguished himself so much that the curators determined to supply him with the means of pursuing his studies at the best foreign universities. He first settled at Groningen, and afterwards at Leyden, where he became assistant to Golius, the best orientalist of that age. He also took lessons in Arabic and Turkish from Ahmed Jon Ali, a Mohammedan, from Morocco, of whom he often speaks in his works. Golius had hoped to take his pupil with him to the East, but the senate of Zurich interfered, and Hottinger, after visiting France and England, returned home. In 1653, the chairs of rhetoric, logic, and scriptural theology were offered him, and he had only filled them for two years, when, at the urgent request of the Elector Palatine, he was allowed to remove to Heidelberg for three years. He there taught the Eastern tongues and biblical criticism with such success and distinction, as to revive and spread the fame of the university. Prolonging his stay in the Palatinate till 1661, he returned to Zurich in that year, and was made rector of the university. His reputation still continued to increase, and in 1667 he received such flattering offers from Leyden, that he resolved to accept them. Before setting out for this new sphere of labour, he went to visit a small property which he possessed a few miles from Zurich. In crossing the Limath, the boat in which he was seated, with his wife and family, was upset, and Hottinger, who might have preserved his own life, was drowned in attempting to save that of his wife.

Hottinger's principal works are,—*Exercitationes Anti-Morinianæ de Pentateucho Samaritano*, Zurich, 1644, in 4to; *Erotematum Linguæ Sanctæ libri duo, cum Appendice Aphorismorum*, ibid. 1647; *Thesaurus Philologicus, seu Clavis Scripturæ qua quidquid fere Orientalium, Hebræorum maxime et Arabum habent monumenta de Religione ejusque variis speciebus, Judaïsmo, Samaritanismo, Muhamedismo, Gentilismo*, &c., ibid. 1649; *Historia Ecclesiastica Novi Testamenti*, in nine parts, 1651–1667; *Historia Orientalis ex variis Monumentis Collecta*, ibid. 1651, in 4to; *Grammaticæ Chaldæo-Syriacæ libri duo*, ibid. 1652; *Analecta Historico-Theologica, octo Dissertationibus proposita; Dissertationum miscellanearum Pentas*, ibid. 1654, in 8vo; *Dissertatio de Subsidiis Analyseos Sacræ, ubi prolixe de Sensu Verborum Institutionis Cœnæ Dominicæ*, ibid. 1654, in 8vo; *Juris Hebræorum leges* 261, *juxta Legis Mosaïcæ ordinem ac seriem depromptæ; Smegma Orientale sordibus barbarismi contemptui præsertim Linguarum Orientalium appositum*, Heidelberg, 1657, in 4to; *Grammatica Ling. Hebr. Chald. Syr. et Arabicæ Harmonica*, ibid. 1657; *Cippi Hebraïci*, ibid. 1659, in 8vo; *Primitiæ Heidelbergenses*, ibid. 1659; *Dissert. Theolog. Philolog. fasciculus*, ibid. 1660; *Etymologicon Orientale, sive Lexicon Harmonicon Heptaglotton*, 1661, in 4to; *Epitome utriusque Juris Judaïci, Aphorismis Maimonides exhibita*, ibid. 1661; *Compendium Theologiæ Christianæ Ecclesiarum Orientalium, Syrorum cum primis, Æthiopum, Arabum, et Ægyptiorum; Compendium Theatri Ismaelitici sive Saracenici*, ibid. 1662, in 8vo; *Bibliothecarius tripartitus*, Zurich, 1664, in 4to.

HOUBRAKEN, Jacob, an eminent engraver, was the son of Arnold Houbraken, a native of Holland, and was born Dec. 25, 1698. For some time he worked in obscurity, and had attained the meridian of life before he engaged in the undertaking by which he is best known; a work founded on a plan of George Vertue, who proposed a series of engravings of the greatest men of ancient and modern times. The persons who brought out this great national work were the Knaptons, who employed both Vertue and Houbraken, but chiefly the latter. Some of Houbraken's heads were carelessly executed, especially those of the moderns; but others display a wonderful union of softness and freedom, with good drawing, and a masterly determination of the features, such as are shown in the works of Nanteuil, Edelink, and Drevet. In his desire to avoid the appearance of an outline, he frequently neglected the little sharpnesses of light and shadow which appear in nature, and please, like the accidental semitones in music, in proportion as the variation is judiciously managed. For want of attention to this essential beauty, many of his prints have a hazy appearance, and do not strike the eye with the force which might be expected from the excellence of the engraving. Houbraken lived to a good old age, and died at Amsterdam in 1780. No complete set of Houbraken's prints is now extant, in this country at least. The last that was known to exist was the property of the Duke of Buckingham, but it was broken up and dispersed at the great sale at Stowe in 1848.

HOUGHTON-LE-SPRING, a market-town of England in the county of Durham, and 6 miles N.E. of the town of that name. The inhabitants are chiefly employed in the coal-mines and iron-works. The parish church is a cruciform edifice in the early English style. There is a free grammar-school founded in 1574. Pop. (1851) 3224.

HOUND.

From the combination of various causes, the history of no animal is more interesting than that of the dog. First, his intimate association with man, not only as his valuable servant and protector, but as his constant and faithful companion throughout all the vicissitudes of life. Secondly, from his natural endowments, not consisting solely in the exquisite delicacy of one individual sense, that fineness of olfactory nerve which enables him to follow his master or to track his victim; not merely combining memory with reflection that soars above instinctive preservation or self-enjoyment; but qualities of the mind that absolutely stagger us in the contemplation of them, and which we can alone account for in the gradation existing in that wonderful system which (by different links of one vast chain, extending from the first to the last of all things, till it forms a perfect whole) is placed, as Professor Harwood elegantly expresses it, "in the doubtful confines of the material and spiritual worlds." It might have been instinct that enabled Ulysses' dog to recognise him on his re-landing in Ithaca, after an absence which must have set the powers of memory at defiance; and he recognised him with all the acuteness and affection which instinct boasts; *but what caused him to expire at his feet on the sudden dawn of unexpected happiness?* The heart of man could go no further than this; and although perhaps the poet's fiction is only present to us in this instance, by what name can we call those tender affections, those sincere attachments, those personal considerations, which we ourselves have witnessed in these faithful creatures towards human kind? Virtue alone is too cold a term, as almost every good quality to be found in animated nature is to be found here; and when we reflect upon the miserable existence so often the lot of this kind-hearted animal in this world, and the more than uncertainty that, as Byron says, he will be

> "Denied in heaven the soul he held on earth,"

we cannot but feel regret that he should be without his reward. But yet this is a point not exactly decided upon by man; at least it has been considered as a fit subject for speculation by deep and able thinkers. Locke, for example, doubted whether brutes survive the grave, because there is no hint given of it in revelation; but Dr Priestley thought, if the resurrection of the dead be within the proper course of nature, and there be something remaining of every organized body that death does not destroy, there will be reason to conclude that they will be benefited by it as well as ourselves. "The misery," says this forcible writer, and great moral philosopher, "some animals are exposed to in this life, may induce us to think that a merciful and just God will make them some recompense hereafter."

But no animal has met with more variety of respect shown towards him than the dog has. By the law of Moses he was declared unclean, and was held in great contempt by the Jews, as also by the Turks, and kept by both merely for the purposes of scavenging their streets. In every part of the sacred writings, as also in those of Greece and Rome, not only are images introduced from the works of nature, and metaphors drawn from the manners and economy of animals, but the names of them are applied to persons supposed to possess any of their respective qualities. Thus our Saviour, adopting this concise method, applies the word "dog" to men of odious character and violent temper; and, as with us at present, the term of reproach, "he was a son of a dog," was in common use among the Jews. The wife, Abigail (1 Samuel xxv. 3), "was a woman of good understanding, and of a beautiful countenance; but the man (Nabal) was churlish and evil in his doings, and *was of the house of Caleb.*" Literally it is, "he was the son of a dog." The Egyptians, however, held the dog sacred, and were reproached with worshipping him in their god Anubis, as Juvenal complains in his fifteenth satire:

> "Oppida tota Canem venerantur, nemo Dianam,"

—although hieroglyphic researches now show the head of this deity to have been that of a jackal, not that of a dog. Anubis, says Strabo, is also the city of dogs, the capital of the Cynopolitan prefecture. "Those animals," says he, "are fed there on sacred aliments, and religion has decreed them a worship." This absurd adoration is confirmed by Diodorus Siculus and Herodotus; and Rome having adopted the ceremonies of Egypt, the Emperor Commodus, when celebrating the Isiac feasts, shaved his head, and himself carried the dog Anubis.

We have good reason to believe that England (in a great measure from the congeniality of its climate) has long been famous for dogs, which, on the authority of Strabo (lib. iv., p. 199), were much sought after by all the surrounding nations. So high indeed in repute were British dogs amongst the Romans after the reduction of our island, not only for excellence in the chase, but fierceness in the combat, that an officer from that country was appointed to reside in the city of Winchester, for the express purpose of collecting and breeding them to supply the amphitheatre, as well as the imperial kennel, at Rome. Nor was this all. As a kind of earnest of our present celebrity in the various sports of the field, all the neighbouring countries, as Dr Campbell remarks, "have done justice to our dogs, adopted our terms and names into their language, received them thankfully as presents, and, when they have an opportunity, purchased them at a dear rate."[1] Thus we find, that when King Alfred requested Fulco, archbishop of Rheims, to send some learned ecclesiastics into England, he accompanied his letter with a present of several dogs, being the most valuable he could, in those times, bestow. The congeniality of our climate has contributed much to this excellence, as our dogs, hounds especially, are found to degenerate in most others; which Somerville alludes to in his poem of the *Chase.*

> "In thee alone, fair land of liberty,
> Is bred the perfect hound, in scent and speed
> As yet unrivall'd, while in other climes
> Their virtue fails, a weak degen'rate race."

We do not benefit much by research into ancient authors on the subject of dogs; for although they have been much written upon, and immortalized in song by Oppian, Claudian, Gratius, and others (Virgil says little about them), yet, from our ignorance of the sort of animal bred in their time, and the use they made of them, *as sportsmen*, we can draw no parallel between them and our own that would tend to a good purpose. No doubt the "canis *vestigator*" of Collumella, and the "canis *odorus*" of Claudian, were of what we term a low-scenting sort, as the epithets applied to them signify; but it would be difficult to pronounce an opinion upon the καστόριαι, or the ἀλωπεκίδες, of Xenophon, although the characteristic properties of good hunting hounds are very well and accurately laid down by him in the third chapter of his Κυνηγετικος, as well as their defects in form, &c., equally clearly exposed; and his observations on these points might be perused with advantage by huntsmen of the present day.

Great encouragement has been given to the breeding of hounds in England by the various monarchs who have reigned over it. Henry II. was perhaps the first who made himself conspicuous in this department of the sportsman's occupation, being, as one of his historians says of him, "particularly curious in his hounds, that they should be fleet, well-tongued, and consonous." The last epithet is in reference to a property not only little regarded, but nearly lost now, namely, the deep tongue of the old English bloodhound, which Shakspeare alludes to in his celebrated description of those "of the Spartan kind"—

> "So flewed, so sanded, and their heads are hung
> With ears that sweep away the morning dew.
> Crook-knee'd, and dewlapt, like Thessalian bulls;
> Slow in pursuit; but match'd in mouth like bells,
> Each under each:"

which would now be considered a disgrace to any man's kennel, and we believe nowhere to be found bearing the faintest resemblance to the picture drawn of them by this master-hand.

In Queen Elizabeth's time a classification was made by Dr Caius, physician to the queen, in his treatise *De Canibus Britannicis*, of the different kinds of dogs peculiar to Great Britain; but many of the names (the sleute or sleuth hound of the Scotch, for example) having since become obsolete, they were again classed by Mr Daniel, in his *Rural Sports*, which work contains a full and satisfactory historical account of their origin, different crosses, &c., under the following genealogical heads:—Shepherd's Dog, Iceland Dog, Lapland Dog, Siberian Dog, Hound, Terrier, Large Spaniel, Small Spaniel, Water Dog, Small Water Dog, Bull Dog, Large Danish Dog, Irish Greyhound, English Greyhound, and Mastiff. Taplin, in his *Sporting Dictionary*, expresses his surprise that the Pointer is omitted; but we consider the Pointer as a dog of foreign extraction, and to our early ancestors certainly unknown.

The original stock from which English hounds have been bred would be very difficult to determine upon; but one thing is certain—namely, that the several sorts with which the country once abounded have been becoming fewer and fewer in the course of the last hundred years, and now centre in three varieties,—namely, the fox-hound, the harrier, and the beagle. The stag-hound is gone, at least there is no pack of stag-hounds now kept in Great Britain, the last having been disposed of and sent abroad soon after the stag-hunting establishment in Devonshire was broken up, a few years ago. The beagle is also become rare; and otter-hounds, such as we may conclude the καστόριαι of Xenophon to have been, never existed in this country, the dog used in hunting the otter being the common harrier; and perhaps the parent of all, the majestic blood-hound, whose

---

[1] Campbell's *Political Survey*, vol. ii., p. 205, note D.

> "Nostrils oft, if ancient fame sings true,
> Trace the sly felon through the tainted dew,"

is at present very thinly scattered, here and there only, at keepers' lodges in some of our royal forests. But we more than doubt whether a true specimen of the original English blood-hound exists in England at all at the present day; nor is this a matter of regret, as, unlike the rest of his species, his character is said to be that of decided enmity to man. Strabo describes an attack upon the Gauls by these animals, and likewise says they were purchased in Britain by the Celtæ for the purposes of war, as well as those of the chase; but it is doubtful whether the most savage of this race would devour man without being trained to it, which we know that they were on a late horrible occasion, when, as stated in Rainsford's *History of St Domingo*, they were fed upon blood; and a figure representing a negro, containing blood and entrails of beasts, was the object they were led to pursue. In the West Indies the blood-hound was reared and kept solely for following the track of runaway negroes, as the sleuth-hound of the Scotch was early applied to discover the haunts of robbers; and to the same purpose also on the confines of England and Wales, where the borderers preyed on the flocks and herds of their neighbours whenever an opportunity offered. Of deer-stealers, who were so numerous a century or two ago, they were likewise the terror; and well might they have been so, for when once fairly laid upon the foot of one, they seldom failed to hunt up to him. But it is in the civil wars of our own country that blood-hounds are placed in the most conspicuous light, when used to reveal the hiding-places of Wallace and Bruce; and the poetical historians of the two heroes allude to their services to their masters, as well as to the escapes they had from those of their various enemies.

The distinguishing features of the English blood-hound are long, smooth, and pendulous ears, of from eight to nine inches in length, with a wide forehead, obtuse nose, expansive nostrils, and deep flewed, with an awfully deep but highly sonorous tongue. The prevailing colour is a reddish tan, darkening to the upper part, often with a mixture of black upon the back, and extending over. In short, the deep-flewed southern hare-hound, now almost extinct in England, very nearly resembles the English blood-hound in form and colour; and a person may picture to himself the latter, by supposing an animal considerably larger than the old southern hound. In height he is from twenty-six to twenty-eight inches, and sometimes more; but he is very seldom to be found except in the neighbourhood of a deer-park, where he is kept to track venison stealers. "Associations for the prosecution of felons" also keep them to assist in sheep-stealing cases. The Duke of Bedford has some fine specimens of this kind of dog, whose pedigree can, it is affirmed, be traced back for 300 years. Lord Yarborough's breed is also very famous, and it was very much improved about 1840 by a cross with Lord Fitzwilliam's "Bellman," who was considered to be to blood-hounds what "Furrier" and "Trogan" were to fox-hounds. Modern blood-hounds are rather deficient in the head, lips, and ears, but still they are very handsome, and swifter of foot than their ancestors. The blood-hound of the West Indies is also about the same height, but differs much in form. He has small, erect ears, the nose more pointed, and the hair and skin hard. His countenance is ill-featured and ferocious; and although not so heavy as the English blood-hound, he is quite as muscular, and very active. The distinguishing property of the blood-hound consists in his never changing from the scent on which he is first laid; and he will hunt by the shed blood of a wounded animal as truly as he will by the foot.

The Stag-Hound.

The English stag-hound, now nearly gone, is little more than a mongrel blood-hound; at least it is reasonable to conclude, that the cross which produced him was directly from the English blood-hound with some lighter animal of a similar species (perhaps a greyhound, or lurcher) approximating his form, to which conjecture his figure and disposition, as well as his *comparative* inferiority of scent, appear to add strength. It is asserted in the *Sportsman's Cabinet*, that the stag-hound "was originally an improved cross between the old English deep-tongued southern hound and the fleeter fox-hound, grafted upon the basis of what was formerly called, and better known by the appellation of blood-hound." But this assertion must have been made without proper reflection; for, in the first place, a cross between the deep-tongued southern and the fox-hound will not produce an animal nearly so large or so strong as the stag-hound; and, secondly, the stag-hound was known in England long before the fox-hound was made use of, or, indeed, before there was an animal at all resembling the one which is now known by that term.

We confess we regret the prospect of the total extinction of the English stag-hound, which, although his form possessed little of that symmetry we now see in the English fox-hound, was a majestic animal of his kind, and possessed the property peculiar alone to the blood-hound and himself, of unerringly tracing the scent he was laid upon, amongst a hundred others; which evinces a superiority, at all events a peculiarity, of nose entirely unknown to our lighter hounds of any breed. The want of being able to distinguish the hunted fox from a fresh-found one is the bane of English fox-hunting; and there are not wanting those who think, that in the breeding of the modern fox-hound, the minor points of high form and blood are more frequently considered than they should be, in preference of a regard to nose.

The Fox-Hound.

The English fox-hound of the present day is a perfect living model; but how he has become such, it is in no one's power to determine. Although we do not like to apply the term of mongrel to an animal we so highly respect, yet

there can be no doubt of his being one of a spurious race, engrafted with care on the parent stock, namely, *the old English blood-hound.* There is, we believe also, no doubt that a century and a half ago there was no animal in the world resembling the present breed of fox-hounds; and that the fox, when hunted at all in Great Britain, was hunted by a dog much resembling what is now known as the Welsh harrier, rough-haired and strong, but of very far from sightly appearance. As all animals, however, improve under the care and guidance of man, until at length they assume the character of a distinct breed; such has evidently been the case with hounds, the breeders of which have, by going from better to better in their choice of the animals from which they have bred, progressively arrived at the perfection we see in them. And such has been the case with all our domestic animals, the breeders of which have alone attained their ends by the choice of individuals of the highest excellence in their kind, and by a judicious selection of size, form, and qualities likely to produce the result. There can be no doubt, then, but that by pursuing this course throughout a number of generations with the hound, an animal has been produced of what may be called quite a new variety in the canine race, answering the description and purposes of our present fox-hound. But the questions may be asked, Whence the necessity for this change, and forcing, as it were, nature from her usual course? Why not be content with the low-scenting, plodding hounds of our forefathers, which, from the superiority of their nose, not only displayed *hunting*, in the strict acceptation of that term, to the highest advantage, but very rarely missed the game they pursued? These questions are satisfactorily answered in a few words; first, as the fox is not now found by the drag, and the number of those animals is so greatly increased, the necessity for this extreme tenderness of nose does not exist; and, secondly, by reason of the blood of the race-horse having gradually mixed with that of our hunters, the sort of hound we have been alluding to was not found to be adapted to their increased speed; and particularly as, in proportion as nature lavished this fine sense of smelling on the old-fashioned hound, was he given to "hang" or dwell upon the scent, thereby rendering the length of a chase (which, to please the present taste, should, like Chatham's battle, be "sharp, short, and decisive") beyond the endurance of a modern sportsman. It is true Mr Beckford, in his *Thoughts upon Hunting*, gives an instance of a pack of old-fashioned hounds, which ran in a string, as it were, one following the other, and yet killing twenty-nine foxes in twenty-nine successive runs, each fault being hit off by an old southern hound. But what would our hard-riding, modern sportsmen think of this as pastime? Nevertheless, all who witnessed, as we have done, the style of hunting of the Devonshire stag-hounds, will remember that there was a close similarity between them in chase, and the pack Mr Beckford speaks of. But, as the same eminent author afterwards observes, it is the dash of the fox-hound of the present day that distinguishes him from all others of his genus, and hounds must now "carry a head."

The breeding a pack of fox-hounds to a pitch bordering on perfection is a task of no ordinary difficulty; the best proof of which is to be found in the few sportsmen who have succeeded in it. Not only is every good quality to be regarded, and if possible obtained, but every fault or imperfection to be avoided; and although the good qualities of hounds are very soon reckoned, their faults in shape and performance present a longer catalogue. Independently of shape, which combines strength with beauty, the highest virtue in a fox-hound is not in the exquisiteness of his nose, but in his being true to the line his game has gone, and a stout runner to the end of a chase. But he must not only thus signalize himself in chase; he must also be a patient hunter, with a cold scent, or with the pack at fault. In short, to be a hard runner and a good hunter, and steady on the line, which "a good hunter" implies, constitutes a perfect hound, when combined with good form.

The faults of hounds, too often innate, can only be cured by education. The greatest of all are, skirting, or not being true on the line, and throwing the tongue improperly; first, without a scent, which is known by the term babbling; secondly, not throwing it at all, or running mute; and, thirdly, on a wrong scent, which is called running riot. The latter, however, is the least vice of the two, because generally curable by the lash; but the fault of skirting is too often innate; at all events, too often incurable. Thus has the breeder of the hound to guard against propensities as well as faults; and a late accredited writer on the subject says, "In modern times, the system of hunting is so much improved, so much more attention is paid to the condition of hounds and their style of work, that in this enlightened age a master of hounds thinks it a reflection on his judgment if *one* hound in his pack is detected in a fault."[1]

The selection of dog and bitch to breed from is a nice point for a master of hounds, or his huntsman, to decide upon; but if he aim at excellence, he must keep his eye on perfection. In no animal is perfect symmetry so desirable as in a fox-hound, for without it there is no dependence on his services, however good may be his nature. We will first describe him in the words of a very old writer, and afterwards in those of Mr Beckford, when it will appear that there is a strong resemblance in the portraits drawn by each. "His head," says the former, "ought to be of middle proportion, rather long than round; his nostrils wide; his ears large; his back bowed; the fillets great; the haunches large; the thighs well trussed; the ham straight; the tail big near the reins, and the rest slender to the end; the leg big; the sole of the foot dry, and formed like a fox's, with the claws great." The latter says, "There are necessary points in the shape of a hound which ought always to be attended to; for if he be not of perfect symmetry, he will neither run fast nor bear much work; he has much to undergo, and should have strength proportioned to it. Let his legs be straight as arrows; his feet round, and not too large; his shoulders back; his breast rather wide than narrow; his chest deep; his back broad; his head small; his neck thin; his tail thick and brushy; if he carry it well so much the better." Now the hound that would answer to either of these descriptions would disgrace no man's kennel, and one resembling the latter would be an ornament to it; but with regard to the former, it must be borne in mind, that it is from the pen of a sportsman who wrote a century and a half ago, when, as has been before observed, there is reason to believe no animal in the perfect form of the modern fox-hound was to be found in this or in any other country. Judges of the animal, however, will be disposed to think with us, that there is much of the real character of the *hound* in the sentence we have quoted from this old writer; such as the long rather than round head; the wide nostrils (Pliny says they should be flat, solid, and blunt); and the dry fox's foot. But the "bowed back" appears to spoil all, unless by it is meant that gentle rise in the loins which the judge of hounds admires, and without which the late Mr Chute of the Vine, in Hampshire, who hunted that country for more than thirty years, gave it as his opinion, no hound was able to maintain his speed for an hour over hilly and *ploughed* countries when "it carries;"—a technical term for the earth clinging to the foot, which it will do after a slight frost on the preceding night; necessarily adding much to the natural weight of the hound. Beckford gives us the modern fox-hound, and perfect, with the exception of the mention of one or two material points. "His chest should be deep," says he, "and his back broad;" but he has omitted a point much thought of by the modern sportsman, namely, *the back ribs*, which should also be deep, as in a strong-bodied horse, of which we say, when so formed, that he has a good "spur-place," a point highly esteemed in him. Nor is either of these writers sufficiently descriptive of the hinder legs of the hound; for although the "large haunch and well-trussed thigh" of the former denote power and muscle, nevertheless there is a length of thigh discernible in first-rate hounds, which, like the "well let-down hock" of the horse, gives them much superiority of speed, and is also a great security against laming themselves in leaping fences, which they are more apt to do when they become blown, and consequently weak. The fore legs "*straight as arrows*" is an admirable illustration of perfection in those parts, by Beckford; for, as in a bow or bandy legged man, nothing is so disfiguring to a hound as his having his elbows out, which is likewise a great check to speed. In some countries the round, cat-like foot is indispensable, and agreeable to the eye in all; but we would not reject a well-shapen puppy in other respects for somewhat of an open foot, provided his ancles or fetlocks were good, *a point we consider of the greatest consequence to all quadruped animals.* The shoulders of the fox-hound should resemble those of the horse—oblique, but at the same time strong; for a narrow-chested hound is almost certain to get shaken by hard work, and consequently unlikely to endure beyond his third season.

---

[1] Colonel Cook's *Observations on Fox-hunting*, &c.

As Beckford recommends the small head, we may presume the form and fashion of this point began to be changed in his time, and has, we think, been carried to too great an excess in the fox-hound of the present day, particularly in one or two kennels (the Belvoir, for example), where very short, as well as small heads, were a leading characteristic. For ourselves, we like some length of head in the fox-hound, not being able to divest ourselves of the idea of a cross with the pointer when we see him with a short head and a snubbed nose. Beckford also says the neck should be thin. We would add, *moderately thin.* We dislike a thin neck in any animal but the cow or the stag; at the same time we dislike a short, thick neck in a hound. His neck should be moderately long and moderately thick, with the muscles clearly developed; it should rise gracefully out of his shoulders, with a slight curve or crest, and, completely to satisfy the eye, should be quite free from exuberances of flesh and hair on the lower side of it, called by huntsmen "chitterlings" or ruffles, the hound having them being termed "throaty;" although there are numerous exceptions to this rule, as some of the best hounds England ever saw have been throaty; and although we are aware that one individual instance will prove neither the rule nor its exception, we can go as far back as to Mr Meynell's famous stallion hound *Gusman*, for as throaty, and yet as good a fox-hound as we ever remember to have seen. We agree with Beckford that the "tail," now called stern, of a hound, should be "thick," and moderately "brushy;" and if well carried, it is a great ornament to a fox-hound. But there is one part of it which the master of a pack likes to see nearly deprived of its covering, and that is its tip, which, when in that state, is an infallible proof of a hound being a good, and not a slack, drawer of covers.

But to return to breeding the fox-hound. In the breeding of some animals, beauty of shape is often dependent on the caprice of fashion, or the taste of the breeder; but in the breeding of hounds no such latitude can be given, for here beauty, or symmetry of shape, is alone in reference to utility, and adaptation of parts to the purposes to which they are to be applied. Yet the breeder of fox-hounds has one point further to go; he must, as we before remarked, guard against *propensities*, which run in the blood of these animals perhaps stronger than their good qualities, and will sooner or later break out in their work. In the election then of a dog for a bitch, or a bitch for a dog, these matters must be attentively considered: and no man should breed from hounds of either sex that come under any of the following denominations, viz., not of a docile sort, but very difficult to enter to their game; given to run mute; to hang on a scent; or to be skirters; not only not true to the line, but given to run riot either in cover or in chase; and, above all things, if found evidently deficient in nose, and not able to run at head. Good constitution should likewise be looked to; but we would not reject a stallion hound, or a brood bitch, merely for being slack drawers, or for not being always at the head in chase, provided they were well bred, of good form, and true to the line, in cover, and out.

As to the proper combination of form, that must be self-evident to the breeder of hounds. If a bitch is a little high on her leg, or light, she should be put to a short-legged, strong dog, and of course *vice versa;* if rather light in her tongue, that defect may be remedied by an opposite property in a dog. The defects in legs and feet can only be remedied by such means; and fortunate is it for the owner of an otherwise perfect and excellent bitch, that such remedies are at hand. Length and shortness of frame, as well as coarse points, are all to be obviated and altered in the same way, making allowance for the fact, that the laws of nature are not *always* certain. Constitution can likewise be mended by having recourse to that which is good (and none so easily detected as the dog's); and colour changed if required. In fact, as Beckford says, "It is the judicious cross that makes the complete pack;" and it was the remark of this practical writer, therefore high authority amongst sportsmen, that "he saw no reason why the breeding of hounds may not improve till improvement can go no further." The question may be asked, is not his prediction verified?

But the act of crossing hounds, as indeed all other animals, although never thoroughly divested of chance, is one of more difficulty than most people would imagine, and one indeed which, by its results, would often baffle, if not puzzle, the profoundest of our modern physiologists. Our space will not admit of our going at length into this intricate subject, but great mistakes, we conceive, have been made by masters of fox-hounds, in breeding too much in-and-in, from nearest affinities, instead of having recourse to an alien cross. This was peculiarly apparent in the packs of two very celebrated masters of fox-hounds, the late Sir Thomas Mostyn, Bart., and the late John Corbet, Esq., of Sundorne Castle, Shropshire (the former of whom hunted

Oxfordshire, and the latter Warwickshire, each for upwards of thirty years), who bred in-and-in—Sir Thomas from a bitch called *Lady*, and her produce; and Mr Corbet from a hound called *Trojan*, and his produce—to the great injury of their respective packs. We are aware it is asserted that a pack of fox-hounds should have the appearance and character of being of one family; but this expression is not to be taken in its literal construction. It is in the conformity of their character and appearance that they should bear a close resemblance to each other, and not in their close consanguinity. It is true, the celebrated pack of Mr Warde, the present father of the field, and a master of fox-hounds for the unparalleled period of fifty-seven years, which sold for 2000 guineas, only contained, in 1825, three couples of hounds not of his own blood, and those the produce of one stallion hound, Mr Assheton Smith's *Reubens*. But we have no proof of Mr Warde's hounds being better for adhering so closely to his own sort; on the contrary, it is the opinion, we believe, of the sporting world, reluctantly admitted, in consideration of the well-merited celebrity of of their owner, that, latterly, the slackness of this renowned pack, unrivalled in fine form, was to be attributed to that circumstance. On the other hand, the rare but valuable combination of dash and nose, a match for the cold and ungenial Oxfordshire hills, for which the Duke of Beaufort's pack has been so long conspicuous, has been traced to his grace's late huntsman, Philip Payne (said by Colonel Cook, in his *Observations on Fox-Hunting*, "to be the best judge of breeding hounds in the kingdom"), going from home for his blood, and sending his bitches to the celebrated stallion hounds of the best kennels within his reach. This, however, it must be remembered, is not within the command of every man's purse, the expenses attending sending bitches to a distance, under any circumstances, being heavy; as not only must they be placed under the care of a trusty servant on their journey, but there are other occult expenses attending them, which none but masters of hounds are aware of. It is, however, a notorious fact, that the produce of some stallion hounds, if they have a fair chance by the bitches, seldom fail in turning out well; and, perhaps, the most signal instance of "like begetting like" in this species of animal is that of Mr Osbaldeston's *Furrier* having been the sire of an entire pack in that gentleman's kennel when he hunted the Quorndon country in Leicestershire, which he would occasionally take to the field, amounting to more than thirty-five couples, although, as may be supposed, they were generally mingled with the rest of his kennel, which at that period contained a hundred couples of hounds. These Furrier hounds gave little trouble in the entering of them, and proved very true line-hunters, and everything that fox-hounds should be. The annals of fox-hunting likewise record similar instances of the peculiar properties of stallion hounds transmitting their virtues to many succeeding generations, especially in the instances of the Pychley Abelard, the Beaufort, and the New Forest Justice, Mr Ward's *Senator*, Mr Meynell's *Gusman*, Mr Muster's *Collier*, Mr Corbet's *Trojan*, Lord Yarborough's *Ranter*, with many others of more recent days, but too numerous to mention here. Perhaps at present the Yarborough and Fitzhardinge kennel blood is in the highest repute, and they generally run about twenty-three inches.

The size, or, we should rather say, the height of a fox-hound, is a point upon which there has been much difference of opinion. The long-established pack of the late Mr Chute were at least three inches below the standard of his neighbour Mr Villebois's large pack; also as much below that of his Grace the Duke of Cleveland, who had for many years also a large and a small pack; and at least four inches lower than Mr Warde's, in whose kennel were hounds full twenty-six inches high. Various arguments are made use of by the advocates of large and small hounds. Those of the former assert that they get better across a deep and strongly fenced country than smaller ones; whilst the admirers of the latter insist upon their being better climbers of hills, more active in cover, and quicker out of it when their fox is gone; and are oftener found to be perfect in form and shape. As to uniformity in size, how pleasing soever it may be to the eye, it is by no means essential to the well-doing of hounds in the field, and has been disregarded by some of our first sportsmen, the great Mr Meynell for one, who never drafted a good hound for being over or under size; neither did Mr Assheton Smith, when he succeeded to his, Mr Meynell's, country. The great object of both was to breed them with muscular power and bone, combined with as much symmetry as could be obtained; and to be equal in speed and good qualities, rather than equal in height.

We consider the proper standard of height in fox-hounds to be from twenty-one to twenty-two inches for bitches, and from twenty-three to twenty-four for dog hounds; but some masters of hounds consider that the perfection of breeding is to get the bitches to twenty-three. The late Sir Richard Sutton had once several twenty-five inch Fife dogs in his kennel, but he eventually preferred them smaller. The minimum and maximum size of the last seventy years would have been found in the kennels of Mr Chute and Mr Warde; the Duke of Cleveland and Mr Villebois coming next to Mr Warde in what may be called the maximum class. Mr Chute's motto over his kennel door was "multum in parvo;" and although full of power, and neat, his hounds did not more than average twenty-one inches. On the other hand, many of Mr Warde's bitches, the most splendid animals of their kind and sex, were better than twenty-three, and some of his dog hounds twenty-six, inches high, which was about the standard of the original Devonshire stag-hounds. It may be said of hounds, however, as has been said of horses, that their height has little to do with their size, as far at least as their powers of action are concerned; and doubtless in all animals that labour, a medium height is the best.

The amount of hounds bred annually will depend on the strength of the kennel, and the number of days' hunting in the week which the country they are intended for requires. From sixty to eighty couples are about the complement for a four-days-a-week country, which will require the breeding of a hundred couples of puppies every year, allowing the usual diminution of the entry by malconformation, under size, and that bane to the kennel, the distemper, which often takes off a moiety of them. As the period of gestation in the female dog is somewhat over two calendar months, the fox-hound bitch should, if she can be spared, be put to dog in January, as then she will litter in the spring, when the weather is comparatively mild (cold being destructive of young animals of this sort), and the puppies will then come early into kennel, generally be of good size, and powerful; and be entered without loss of time. The tips of their sterns being pinched off, and their dew-claws cut, whelps should be taken to their walks at about two months old; and if to one where there is plenty of milk or whey, they will be the better for it. Whelps walked at butchers' houses grow to a great size, but they are apt to be heavy-shouldered and throaty, and otherwise out of shape. If possible to avoid it, puppies should never be tied up, as perpetually drawing at the collar-chain throws their elbows out, and otherwise damages their legs, particularly by spreading their feet, and altering the form of their ancles, although it is sometimes almost impossible to avoid it, from their proneness to do mischief. If old bitches are bred from, they should be put to young dogs, and of course, *vice versa*; and a bitch should not be worked for at least the last month of her time; and immediately on her whelps being taken from her, a dose of physic should be given her.

It is said that the dog in a state of nature is subject to few diseases, and for these he finds his cure by an instinctive faculty; in a domesticated state, however, he is subject to many, and some of an awful nature, which may be classed among the *opprobria medicorum*, no certain remedy being discovered for them. Amongst these is one called the distemper, not known by our forefathers, but at present become a sort of periodical disorder in kennels, to the destruction of thousands of young hounds annually. The first symptoms of this disease are, generally, a dry husky cough; want of appetite, and consequent loss of flesh; extreme dulness, and a running from the nose and eyes. As the disease advances, it is attended with twitchings of the head, while the animal becomes excessively weak in the loins and hinder extremities; is greatly emaciated; runs at the eyes and nose, and smells very offensively. At length the twitchings assume the appearance of convulsive fits, accompanied with giddiness, which cause the dog to turn round; he has a constant inclination to dung, with obstinate costiveness at one time, or incessant purging at another. Finally, the stomach becomes extremely irritable; everything swallowed is instantly thrown up; and the dog generally dies in a spasmodic fit.

For the cure of this disorder many remedies have been prescribed; but as none of them can be relied upon as specific, we decline giving them,[1] and prefer transcribing the following observations of an intelligent and experienced huntsman in the service of a noble duke, accompanied by a comment upon it by a noble lord, also a practical sportsman, hunting his own fox-hounds.

"As soon," says the former, "as the young hounds come in from quarters, a sharp look-out is kept for the distemper; and as soon as any of its symptoms appear, a dose of cold-drawn castor-oil is given, and the following morning a dose of calomel and jalap. About seven grains of the former and twenty of the latter made into a bolus, and put over their throats before they have tasted anything, and their heads coupled up above the level of their bodies for two hours, so as to prevent them from vomiting up the medicine, which they are certain to do if this is not carefully attended to. They are then to have their broth and their meat. The oil and bolus to be repeated in a day or two as symptoms require; that is to say, if the fever runs high, repeat the bolus, and, if only to keep the bowels open, the oil in small quantities. Indeed the great thing is attending to circumstances, and acting accordingly; as, for instance, nothing can be more different than when flux attends the distemper, and when fits and obstinate costiveness is the case. I believe, however, that at first a good scouring in both cases is of service. In flux, of course, don't repeat the calomel, but take moderate means to stop it, as flux in a minor degree tends to keep off both fever and fits. To allay the flux, arrow-root, or boiled milk and flour porridge. There is no doubt that laudanum is the surest method to stop it, but then it is sure to end with fits. Fits at the beginning are no bad sign, and at the end nothing can be worse. I never either approved of bleeding or vomiting in the distemper; the first weakening too much, the latter creating and adding to the irritableness of their stomachs."

"With the foregoing plain, sensible, and simple treatment," says the noble lord in his comment on the foregoing observations, "my junior experience perfectly agrees with the opinion of ———; but I revert to what he justly adds about 'circumstances,' and differ with him about the bleeding, as I think a good scouring out, and bleeding, before anything symptomatic of the disease has fairly begun, highly commendable. But, *vice versa*, for instance, if you bleed, after the disease has fairly taken root, the lungs, nine cases in ten, being affected, it is ten to one you kill the dog; but if done early in the day, I cannot but think it is of much service, prevents fever, and in many cases makes the disease less violent. I think perhaps the treatment of whelps, after they come in from their healthy walks to the close confinement of sometimes an ill-kept kennel, is the cause of the distemper taking more violent hold of them than it otherwise would do; and amongst the hundred pretended receipts of many huntsmen, the remark is a justly correct one, of what *may* cure one dog will kill another. But here ——— and his 'circumstances' put you right. What might be advisable would be this:—As soon as your puppies come in, look them attentively over; divide the well-walked whelps from those that have been ill-walked; bleed and scour well out the fat lot, paying of course attention to their diet, cleanliness, and exercise; and cherish the poor lot by the best food, giving them the castor-oil without the calomel or the lancet. But a lot of well-bred fox-hound whelps are not to be left to the care of a whipper-in or a boiler, unless he is a perfectly sober, attentive, and experienced man; for in this disease in the animal, as in the human species, the patient must be most attentively and closely watched."

Kennel Management.

The management of hounds in kennel has undergone great changes for the better since Mr Beckford's day; and, divesting the mind of the inferiority of horse flesh over cow or bullock flesh, the food of hounds, both in its nature and the cooking of it, is such as man might not only not reject, if necessity compelled him to have recourse to it, but such as he would thrive and do well upon. It is a common expression, that "anything will do for dogs," and experience informs us they will exist upon very miserable fare; but hounds, *to be in condition*, must have everything good of its kind, and also well cooked. Were a master of hounds, or huntsman, of the present day, to follow Beckford's advice, of putting his hounds to a horse fresh killed after a hard day, his brother sportsmen would think him mad; nor is there scarcely anything now used in our first-rate kennels but the best oatmeal (Scotch or Irish is the best) one year old, and well-boiled horse flesh, quite free from taint. The meal is put into the copper when the water boils, and should be boiled up a second time, and, in all, for at least two hours; for nothing is worse for the wind of hounds than meal not thoroughly boiled. When taken out of the boiler, it forms a substance resembling coarse rice pudding; and when the fresh flesh, which is shredded, and the broth in which it is boiled, are added to it in the trough, and very well mixed, it forms the best and highest food that can be given to hounds. In some kennels, after the example of that famous huntsman the late Thomas Oldacre, the meal and flesh are boiled up together, with the idea that more of the virtue of the flesh is then imparted to the meal than when it is merely mixed with the broth; but the practice is not general. But such is the difference of constitution in hounds, and the aptitude of some, over others, to gain flesh, or become foul, that persons who are particular as to the condition of their pack have troughs filled accordingly, that is, one with thinner food than another for hounds of the former description. No animal in the world is so soon up and down in his condition as the dog; and, strange as it may appear, the effect of two or three extra mouthfuls of thick meat will be visible on some hounds on the second day after they have eaten them. Nevertheless, the dog being strictly a carnivorous animal, cannot stand hard work without flesh, which he should have a fair allowance of once a-day, according as his constitution may require it. Some masters of hounds, however (the justly celebrated Mr Ralph Lambton one of them), do not feed with flesh on the day before hunting, giving only meal and broth; and this on the supposition that the faculty of scent is more delicately susceptible without it. Young hounds lately come from walks should be fed twice in the day, as they do not always, at first, take to kennel food.

---

[1] Colonel Cook says he has "sometimes" found the following efficacious:—Calomel three grains, cathartic ext. seven ditto, soap seven ditto, emetic tartar one-half grain. Make three pills, and give one every other day. Vaccination was tried in some kennels as a preventive, but it failed, and was abandoned.

Colonel Cook is thus explicit and correct on the subject of feeding hounds, and their condition, the result of many years' experience and great attention to the kennel. "It is quite certain," says he, "a hound too high in condition cannot run a burst, neither can a poor half-starved one kill an afternoon fox; a hound, therefore, cannot be considered as fit to be brought out, if he is either too high or too low. I like to see their ribs, but their loins should be well filled up, and they should be hollow in their flanks: he that is full in the flanks is sure to be fat in the inside, and consequently not fit for work. The feeding of hounds, and the bringing them to cover, able to run a burst, or kill an afternoon fox, is not altogether a thing so easy as some people imagine; in fact, it requires nearly as much trouble to get a hound into condition as it does a horse; and if the greatest attention is not paid to this particular, you cannot expect to catch many foxes. It is the condition of a hound which gives him the advantage over the animal he hunts. Nevertheless their constitutions differ as much as those of the human species; some require thick food, others thin; the same quantity which may be requisite for Ranter, if given to Rallywood, would render him unable to run a yard. Some time before hunting (say about three weeks), they should have plenty of walking exercise, and salts given them once a-week. If a hound is at any time very foul, the following receipt is very efficacious:—Three grains of Æthiops mineral, five grains of calomel, made into a ball: the hound must of course be carefully kept from cold water."

In the summer time, when hounds are out of work, they do not require flesh more than twice a-week, and succulent vegetables in their food are at this time useful. They are also physicked and bled at the close of one season, and before the commencement of the next; and, if necessary, dressed over with a sulphurous mixture during the idle months. But some owners of hounds, and huntsmen, object to dressing them, conceiving that it opens their pores too much, and subjects them to rheumatic affections.

One recent and great improvement in kennel discipline is a small reservoir of water within the walls, of sufficient depth to cleanse the legs of hounds, but not to wet their bodies, which they are made to walk through immediately on their coming home. Upon being turned into their lodging room, they commence licking themselves dry, which, as a dog's tongue is proverbially called his "doctor," is most beneficial to their feet by clearing them of sand or gravel, as well as healing any trifling wounds which they may have received. In the Duke of Cleveland's kennel, this reservoir is filled with broth, which, in addition to its healing properties, induces hounds to lick their feet still more than water does. In flinty countries, the feet of hounds are very frequently wounded, which is a great disadvantage to those a little inclined to do wrong, as they are compelled to miss their turn, and so get above themselves. It also obliges a gentlemen to keep a larger number of hounds than this country would otherwise require.

Hounds are fed on the day before hunting about eleven o'clock A.M., but some delicate feeders require to be let into the troughs a second time. After hunting, they are fed as soon as they have licked themselves dry, which, by the warmth that arises from their bodies when shut up, is very soon effected; and in the summer time it is reckoned safer to feed them in the evening, as they then rest quieter throughout the night, and are less disposed to quarrel.

Colour of Hounds.

In no animal is variety of colours more conspicuous than in hounds, and it adds greatly to their appearance when we see them in a body in the kennel, but still more so in the field. The prevailing ones with the fox-hound are these: Tan (not common); black (not common); black and white and tan (the most common); milk white (not common); red (very rare); blue (the same). Next come the blended, or mixed colours, known in the kennel as "pies." There is the red pie; the blue pie; the yellow pie; the gray pie; the lemon pie (very handsome); the hare pie; and the badger pie, which last is very characteristic of the fox-hound. The fox-hound is sometimes ticked, that is, his coat is dotted with small white specks on a dark ground, but he is rarely what is called "mottled" (motley): and, we believe, what is known by "a blue mottled hound" is not to be found among fox-hounds, being peculiar to harriers and beagles. There was for many years a pack of "blue mottled" harriers kept near Croydon, in Surrey.

It is asserted that the original colour of the English fox-hound was fallow, or pale yellow (Shakspeare speaks of a fallow *greyhound*); and we are inclined to this opinion from its being spoken of in several old works upon hunting, as the "best colour for hounds that hunt the hart or roe;" and there can be no doubt of our fox-hounds being originally descended from that breed of dog, be it what it may. As we know that a recurrence to original colour frequently takes place in animals and birds, after its disappearance throughout several generations, this may probably account for the various pied hounds we see in kennels, the produce of hounds of distinct colours, perhaps merely black and white, and often of those nearly black. Moreover, at Ashdown Park, in Berkshire, an old seat of the Craven family, there is a picture of a pack of fox-hounds, above a hundred years old, in which every hound is either fallow-coloured or red.

The Tongue, or Cry of Hounds.

The cry of hounds, melodious and heart-cheering as it even now is, has lost much of its poetical interest, from the change man has made in the natural organization of the animal from which it proceeds: and we shall never again hear of a master of a pack, after the manner of Addison's knight, returning a hound that had been given to him as an "excellent bass," whereas the note he wanted was a "counter-tenor." The acute Beckford, however, was something of the worthy knight's opinion; for he says, in his *Thoughts upon Hunting*, "If we attended more to the variety of the notes frequently to be met with in the tongues of hounds, it might greatly add to the harmony of the pack." This is well in theory. The natural organization of the dog is musical: he is, in fact, a victim to musical sensibility; and we may reasonably suppose that the notes of his companions in the chase may be as pleasing to himself as to the huntsman; but we more than doubt whether a huntsman of this day would draft a highly-bred and beautiful young bitch, as good too as she looks to be, merely because her light, fox-hunting tongue might be somewhat drowned, and now and then lost, in the general chorus of the pack. He would rather say, "*Let every tongue be a fox*,[1] and I'll leave the rest to chance." But, on a good day for hearing it, what *natural* sound is more delightful and animating than that of hounds in full cry, in the deep recesses of an echo-giving wood?

---

[1] "Every tongue a fox," is a well-known sporting phrase.

The Age of Hounds.

The dog exhibits no exact criteria of age after the first two years, during which time the whiteness and evenness of his teeth are a pretty certain test of his not exceeding that period. An old hound, however, cannot be mistaken if only looked in the face, where he shows old age nearly as distinctly as man. As to the length of services of hounds, that depends upon circumstances. Few are found in a kennel after their eighth year, and *very few* after their ninth; and not many hard-working hounds can "run up," or keep pace with the rest, after their fifth season at most. Hounds are in their prime in the third and fourth years; and although there are a few instances, such as the late Sir Richard Sutton's Lucifer, the Beaufort Nector, and the Cheshire Villager, of their hunting in their twelfth, eleventh, and tenth year, the average of their work cannot, we fear, be placed beyond four seasons. Old hounds are useful in the field, but when they cannot run up with the pack, they should be drafted. The perfection of a pack consists in the great body of it being composed of hounds *quite in their prime.*

Separation of the Sexes.

The separation of the sexes in the kennel *and in the field* is one of the late innovations in the sporting world, and generally considered as a good one. In the first place, it pleases the eye to see a pack of hounds nearly all of a size, which cannot be the case when it is composed of dogs and bitches mixed; and the character of the animal is likewise more uniformly displayed when confined to one individual sex. Secondly, by the total separation of dogs and bitches in the kennel and in the field, the former are less inclined to quarrel, and the latter are more at their ease, than when subject to the constant, and, at times, importunate solicitations, of the male sex. Of their performances in the field, however, when taken into it separately, some difference of opinion exists; and each sex has its advocates. With a good fox before them, and a warm scent, bitches are decidedly quicker, and more off-hand in their work, than dog hounds; but with a colder scent, or at fault, the general opinion is, that they are not so patient, and more given to over-run it. That they are superior in "*dash*," which, Beckford says, is the distinctive characteristic of a fox-hound, we believe is universally acknowledged; and a celebrated master of hounds,[1] who hunted them himself several seasons in Leicestershire, has been heard frequently to say, that if his kennel would have afforded it, he would never have taken a dog hound into the field. That, in the canine race, the female has more of elegance and symmetry of form, consequently more of speed, than the male, is evident to a common observer; but there is nothing to lead us to the conclusion, that, in the natural endowment of the senses, any superiority exists. It is however remarkable, that the Latins, when speaking of hunting, or "sporting dogs," as we call them, generally use the feminine gender, one instance of which is to be found in the second ode of the fifth book of *Horace* (*multâ cane*), which ode every sportsman ought to read, as it gives so pleasing a picture of a country life.

Names.

The naming of hounds and horses has nearly exhausted human invention, as well as classical research. Beckford furnishes a list of more than eight hundred names for hounds, alphabetically arranged. But the naming of hounds is somewhat under metrical control; for it is not only confined to words of two and three syllables, but their quantity, or rather their time, must be consulted. For example, a dactyl, as *Lucifer*, answers well for the latter; but who could holloa to *Aurora?* a trochee, or an iambus, is necessary for the former, the spondee dwelling too long on the tongue to be applied smartly to a hound. But there ought to be a nomenclature, as of old, at every kennel door; for it is but few persons unconnected with a pack that can recollect their names until after a rather long acquaintance with them, from the great similarity of form, character, as well as sometimes of colour, in old-established kennels. "How is it possible," said a young master of fox-hounds a few years ago, "that I should distinguish every hound in my kennel by his name, when I find *three* spots on one side of their body, and *five* perhaps on the other?" There have been, however, and still are, persons who can see a large kennel of hounds *once* drawn to their feeding troughs, and call them all by their names afterwards, the result alone of a keen and practised eye.

The price of hounds is strangely altered within the space of half a century, or less; and on this subject we cannot do better than quote Colonel Cook. "Hounds," says he (p. 6), "have always been much undervalued; we sometimes hear of eight hundred or even a thousand guineas as the price of a hunter, and the sum of three or four hundred is often considered as a mere trifle; whereas a pack of hounds, *on which everything depends*, was only considered worth a a few hundreds. Yet Shakspeare himself appears to have known the value of a hound; for in his "Induction" to the *Taming of the Shrew*, a nobleman returned from hunting thus speaks of his hounds with delight to his huntsman:—

> *Nobleman.* Huntsman, I charge thee, tender well my hounds;
> Brach Merriman,—the poor cur is imboss'd,
> And couple Clowder with the deep-mouth'd brach.
> Saw'st thou not, boy, how Silver made it good,
> At the hedge-corner, in the coldest fault?
> I would not lose the dog for *twenty pound.*
> *Huntsman.* Why, Belman is as good as he, my lord;
> He cried upon it at the meerest loss,
> And twice to-day pick'd out the dullest scent;
> Trust me, I take him for the better dog.

"The sum of twenty pounds for a single hound in Shakspeare's time," continues the colonel, "and that not the best in the pack either, was no inconsiderable price. I am not alluding to 'a lot of curs;' but surely a well-bred, established pack of fox-hounds including brood bitches, and puppies at walk, must be cheap at a thousand or twelve hundred pounds."

How far an established pack of fox-hounds is cheap at a thousand or twelve hundred pounds, is a matter of consideration with reference to concomitant circumstances. We should put the average price at something less than the highest of the above sums, although several packs have been sold for the former sum; and the justly renowned one of Mr Warde fetched two thousand guineas. When blindness unhappily compelled Mr Folgambe to lay aside the scarlet in 1845, his pack was sold for three thousand guineas. The late Lord Middleton gave Mr Osbaldeston two thousand guineas for ten couples of hounds out of his kennel, and the Earl of Stamford gave four hundred and seventy guineas for four couples of Mr Richard Sutton's hounds!

The Harrier.

The modern harrier bears no greater resemblance to the one in use fifty years back, than the hunter of the present day to that ridden by our grandfathers. In fact, he is now nothing less than the fox-hound in miniature, which it is the endeavour of all breeders to have him. Their qualities also are as opposite as their form, the one delighting to dwell upon the scent, the other a little inclined, perhaps, to the other extreme. But the taste of the day for all sports of the field would not endure the tedious exactness of the old psalm-singing harrier; and not only in point of diversion, but on the score of the *pot*, the balance is greatly in favour of the improved variety. Before the old-fashioned harrier, the hare had time to play all sorts of tricks, to double on her foil, and so stain the ground that she often escaped by such means; whereas the modern hound, if the scent be tolerably good, forces her from her foil to fly the country, and very often beyond her knowledge, when a good straightforward run is the almost invariable result. The observation of Mr Beckford holds good here. He could not, he said, imagine a hound too *well* bred to show sport, and kill his game; but he could readily conceive the reverse, when the game ran stout and well.

---

[1] "Sir Bellingham Graham, Bart. of Norton Conyers, Yorkshire.

To the late Sir John Dashwood King, Bart. of West Wycombe Park, Bucks, is the credit due for what may be termed the living model of the present improved harrier; and so characteristically stamped is his sort of hound, now widely spread, that they are recognised by a sportsman at the first glance. Their standard height did not exceed eighteen inches, and therefore, in that respect, they were not an overmatch for their game; but from the great equality of their size and speed, combined with rare hunting qualities, they killed more hares, with good runs, than any other pack in the kingdom, and for many, many years in succession certainly "bore the bell." Sir John kept them more than thirty years, at Bourton-on-the-Hill, Gloucestershire, near the four-shire stone on the Oxford and Worcester road, where his father kept them before him; hunting partly in the vales of Warwickshire and Worcestershire, and partly over the Cotswold Hills, which latter country is famous for the stoutness of its hares, frequently standing an hour before this celebrated pack, after having been driven beyond their knowledge by their *pressing* method of hunting up to them, a method quite unpractised by the old long-eared harrier. The parent stock of this pack was a small fox-hound from the Duke of Grafton's kennel, called Tyrant, whose blood, form, and character, were strikingly apparent throughout; and so great was its celebrity, that it fetched the highest price ever known to be given for harriers, namely, seven hundred guineas, by Lord Sondes of Rockingham Castle, Northamptonshire. Sir John, however, deserved success. He bred upwards of seventy couples of hounds every year, and had an establishment of horses, &c., nearly equal to fox-hounds. The hare-hounds bred for many years by Mr Yeatman of Stock House, Dorsetshire (who lately resigned the Blackmore vale country, in which he hunted foxes), came next to Sir John's in the true form and character of the modern harrier.

The Beagle.

This variety of the dog is now nearly extinct, and for the same cause as the stag-hound. Time is at present considered as too precious to afford an hour at least, and perhaps two, to the hunting down one hare, which is now accomplished in a more off-hand manner, in twenty minutes. To an admirer of nature, however, and of the endowments given to inferior animals, the busy, intelligent, and highly-gifted beagle certainly affords a treat. His form, also, when not out at his elbows, is handsome in the extreme, and his perseverance in chase is exceeded by none. But he has one of the greatest faults that hounds can possess; he is noisy, and dwells upon the scent, whilst his game is flying the country before him. In fact, his only use or value now is (independently of being looked at and admired, for he is a perfect animal of his kind), to accompany a brace of greyhounds when a hare is wanted, and not ready at hand. There is, however, one pack of beagles kept in Dorsetshire, known as the Mountain Harriers, whose performances are much spoken of in the sporting world. Mr Honeywood of Essex had also a most famous pack, averaging from 9 to 10 inches in height, and 9 lbs. in weight, which he sold to Prince Albert; and the celebrated O'Connell used to beguile his winter leisure with a dozen of these tiny favourites, such as have never been surpassed for breed in Ireland.

The Greyhound.

The greyhound has now lost his place in the catalogue of the dogs used in chase, neither can be classed as such, since man has deprived him of the necessary faculty of smell; but he was held in such high estimation in the middle ages, as to be considered as the peculiar companion of a gentleman. He never went abroad without these dogs; the hawk which he bore upon his fist, and the greyhounds which ran before him, were certain testimonies of his rank; and in the ancient pipe rolls, payments appear to have been often made in these valuable animals. But at no period of his existence was the greyhound the symmetrically elegant animal we now see him, nor possessed of nearly so much speed; neither was the diversion of the leash at any time carried on with so much spirit as within the space of the last thirty years, in various parts of Great Britain. But the necessity for, or rather the cause of, the change in the form of the greyhound, may be traced to his being no longer, as formerly, made use of to course and pull down deer, but chiefly to exhibit his speed at our different spirited coursing meetings, for the various prizes contended for, as also in private matches.

The *Courser's Manual or Stud-Book*, by Thomas Goodlake, Esq. (1828), has the following interesting passages on the alteration effected in this species of dog. "In the days of Elizabeth," says the author, "the greyhound seems to have been a fine and effective animal, but approaching more to the bony, wire-haired make of the Highland greyhound represented in the pictures of Edwin Landseer, and deficient in the symmetry and fine glossy coat which mark a high-bred kennel of modern times. It is probable, that during the early part of the seventeenth century, judicious crosses were made, partly from the beautiful Italian greyhounds, which we often see in family pictures, accompanying our fair ancestresses in their parks and plaisances, and partly from the stouter breed of dogs represented in Flemish hunting-pieces; and that even Persia and Arabia, whose greyhounds are not to be despised in point of form and speed, contributed their quota of blood; as it is shown by the history of Cromwell's Coffin Nail, that the wealthier gentry of that period spared no expense or pains in improving the more highly-prized breeds of sporting animals. If we mistake not, some of the pictures of Charles the First contain portraits of greyhounds approaching nearly in point of coat and shape to the present breed."

Speaking of the late Lord Orford, who established the first coursing club that we read of, at Swaffham in Norfolk, in the year 1776, the same writer says, "He could command such an immensity of private quarters, or walks as they are generally called, for greyhounds, that he bred largely, and few possessed the same advantages of selection. He is recorded as having at one time fifty brace of greyhounds; and it was his fixed rule never to part with a single whelp till he had had a fair trial of his speed; consequently he had chances beyond almost any other individual, of having a collection of very superior dogs. Intent on obtaining as much perfection in the breed as possible, he introduced every experimental cross, from the English lurcher to the Italian greyhound. He it was that first thought of the cross with the English bull-dog, in which he persevered in opposition to every opinion, until, after breeding on for seven removes, he found himself in possession of the best greyhounds at the time ever known; and he considered that this cross produced the small ear, the rat-tail, the fine, thin, silky coat, together with that quiet, innate courage which the high-bred greyhound should possess, preferring death to relinquishing the chase." There is something curiously analogous to the sense conveyed by the concluding words of this extract. His lordship fell dead from his horse immediately after witnessing the triumph of his famous bitch Czarina, in a match at Swaffham, having been in vain admonished on the impropriety of taking the field in his then indifferent state of health; and his memory is introduced as a toast at most coursing meetings, as father and patron of the sport. Earls Craven and Stradbroke, and the late Earl Sefton, have always been great patrons of the leash; and on the whole the blood of Figaro is the most uniformly successful that we now possess.

It would be hopeless to speak with any degree of certainty as to the relative running forms of dogs, as nearly every great courser has his *beau ideal* among cracks, past or present, and his own notion as to the best blood. In old times, Snowball stood pre-eminent; and King Cob is said by many to have been the most perfect of greyhounds in his shape. The far-famed litter of six by Figaro out of Bessy Bedlam, produced seven hundred and eighty-two guineas at Mr Brown's sale at Doncaster in 1854. This gives an average of fifty-six guineas for five, while Bedlamite was bought in for five hundred guineas, a price which has, we believe, never been exceeded for a dog. Bessy Bedlam "the invincible" was never led to her hare, and never beaten, winning the twenty-two courses she ran in public. In fact, she and her "Bedlamite litter" won twenty-five first-class cup or stakes, divided eight, and ran up for six, in which 944 dogs were engaged. Cerito and Mocking Bird were also wonderfully successful bitches; and perhaps one of the best "workers" ever out was Lady Harkaway, the property of Father Tom Macguire. The Emperor, Bugle, and Dusty Miller, strains rank very high; and Mr Webb's "War Eagle litter," which owned Foremost as their sire, was "a great fact" in its day.

Stonehenge, who is by far the greatest living authority on the greyhound, considers that there are six varieties of it, and all with different characteristics. The principal of these is the Newmarket greyhound, which is the oldest, and was brought to the highest perfection in the days of Lords Rivers and Orford. They combine stoutness with very high speed, but are seldom first-rate workers with their hare. They require, in fact, a very fast hare to show themselves to advantage, and are often beaten in working by dogs, which but for them, would never have reached the hare at all. The Lancashire greyhound is very like his Newmarket ancestor, but does not show so much "quality" about the head and neck, and is generally rather larger; and some of the best of them have measured 28 inches, and weighed 70 lbs. Their stride is very great, and so is their power of jumping ditches, which are so rife at Lytham and Altcar. Bedlamite, who forms the subject of our plate, is half Lancashire and half Newmarket, and so is Sackcloth, who travelled nearly 3000 miles by the rail in 1853–54 to meetings the season but one before his noble owner died. Yorkshire greyhounds are quite as speedy as either their Lancashire or Newmarket rivals, and are generally of a great size, and rather coarse. No dogs are "cleverer," but this talent sometimes degenerates into a tendency to lurch. The smooth Scotch greyhound has been very much crossed with English blood, and the principal strains are Jason's, Heather Jock's, Waterloo's, and Mr A. Graham's kennel, which has a great deal of the Emperor and Bugle blood in it. A great majority of them run remarkably well in puppy produce stakes, and though their tempers have a degree of uncertainty, and they are not so fast as the Newmarket dogs, they work much more close with a bad hare. The speed of the rough Scotch greyhound is not very great, and they are slow at their turns, but they are exceedingly hardy, and stay well in a long severe stretch with a straight-backed hare. The sixth section, or the Wiltshire dog, is especially bred for stoutness, to cope with the extraordinary hares which are generally met with at Amesbury, Marlborough Downs, and sometimes at Ashdown Park; and his power of stopping himself and getting away at his turns is something marvellous. Modern Wiltshire greyhounds are rather small, stout, and terrier-like, but many of the best old Wiltshire blood, like Billy-go-by-'em, were much larger.

The Terrier.

The terrier is no longer the accompaniment to a pack of fox-hounds, and for the best of all reasons—foxes are not nearly so often digged for as formerly; and his only use was, by his bay, to inform the diggers whereabouts the fox lay; and we suppose he took his name from his being so eager to get under ground. There is also a second reason why he is better left at home. He was seldom steady from *wing*, if he was from *foot*, and thus often the cause of riot. It was, however, a matter of astonishment to behold those which were very highly bred, making their way, as they did, to the end of the longest chases, over strong and wet countries, as well as through the thickest covers, and so often making their appearance at the end of them. At all events, if left behind, they were sure to find their way home in the course of the night, whatever the distance might be. One peculiarity of form was essential to their being sure of getting up to their fox, viz., not too full in the shoulder; and those whose colour was pure white, and who were broken-haired, were generally most esteemed by huntsmen. It was often their lot to lose their life, by scratching up the earth behind them, and cutting off their means of retreat; and they were now and then killed by a fox, the latter a rare occurrence. They were commonly entered to a badger, whose bite is more dangerous than that of a fox. Rough Scotch terriers are considered rather softer in the mouth than they used to be; and the best English terriers are now bred out of a bull-bitch by a smooth English terrier, and run from 11 to 12 lbs. Mr Collier has a good breed of them, and the Duke of Beaufort's are also especially famed. (C. A.) (W. H. L—Y.)

HOUSEHOLD, The Royal. In the preface to the *Liber Niger Domus Regis Edw. IV.*, we are told that King Edward III. was "the first setter of certainty among his domesticks upon a grounded rule. He appointed duties to his offices and officers by a formal and more convenient custumate, more certain than was used before his time; he framed his new statutes, commandments, and charges, upon every officer inward and outward." Upon this work King Edward IV., with the advice of his great council, founded his *Household Book*. The table of the king, and the daily allowance of provisions, fuel, and lights to peers of each rank when in attendance upon the king, and to all his chief officers, attendants, and servants of every degree, on ordinary and on festival occasions, are carefully particularized; as are also the king's alms and gifts, the wages of every class of his servants, and the robes and liveries for his knights, officers, and domestics.

Henry VII. ordained new articles for the government of his household. Henry VIII. found it necessary to make still further regulations, particularly to prevent the court from being overrun by idlers and the retainers of the officers. In the ordinances made in the 31st Hen. VIII., the porters at the gate are enjoined "not only to exclude servants, vagabonds, and rascalls, but alsoe that they doe not suffer any vagabonds, rascalls, or boyes to enter in at the gate at any time, and that one of them shall, three or four times in the day, make due search throughout the house, in case that negligently at any time any boyes or rascalls have escaped by them, and entred the gates, that thereby they may find them out and put them out againe."

In the royal household in feudal times the lowest offices were filled by persons of consideration, unfitted both by their rank and incapacity to perform the duties attaching to them. The supplies for the extensive establishment were made on the system of *purveyance* and *receipt in kind;* and the royal purveyors seized provisions wherever they could find them, paid for them only in such manner, and at such prices as the household officers thought proper to fix, and deposited them in the king's magazines.

This system of purveyance, after many previous attempts by statute to moderate its obnoxious uses, was abolished in 12th Chas. II. In 1780 Mr Burke introduced his plan of economical reform, in which the royal household formed a conspicuous part. He represented it as formed upon manners and customs which had long since expired, and as retaining ancient officers whose duties had long since ceased. He succeeded, two years later, in obtaining an act (22 Geo. III., c. 82) by which the following offices were suppressed:—Principal officer of the great wardrobe, principal officer of the jewel office, treasurer of the chamber, cofferer of the household, offices of the six clerks of the board of green cloth, paymaster of the pensions, master of the harriers and fox-hounds, and master of the stag-hounds.

The household expenses must have been very great. *Madox* remarks upon the magnificence of the Norman kings; and Stow, in his *Annals*, relates that "the person of King Richard II. was guarded wheresoever he lay by 200 men; that he had about him thirteen bishops, besides barons, knights, esquires, and others, inasmuch that to the household came every day to meat 10,000 people." The charge for King Edward IV.'s household was L.13,000 yearly. The statutes of Eltham, 7th Hen. VIII., give particular articles of diet, wine, &c., to be served to every person of the household, and the quantity and price of every article, the expenses of the stables, and the salaries of all the members and servants of the establishment. In the *Household Book* of King William and Queen Mary, 1689, the diet of the household is computed at L.15,000 yearly, and the total charge at L.76,038. Since the reign of King William III., parliament at the commencement of each reign has appropriated a fixed sum for the civil list of the sovereign. Thus—

To William III.	L.700,000	a-year.
... Anne	700,000	...
... George I.	700,000	...
... George II.	800,000	...
... George III.	800,000	...
Increased in 17th year of reign ...	900,000	...
... George IV.	1,050,000	...
... William IV.	510,000	...
... Victoria	385,000	...

Of this last the application is thus limited:—Privy purse, L.60,000; household salaries, and retired allowances, L.131,260; household expenses, L.172,500; royal bounty, alms, and special services, L.13,200; leaving an unappropriated balance of L.8040, which may be applied in discharge of any of the other classes of charge.

But these sums throw little light upon the comparative grants for the sovereign's household and personal expenses. Prior to the Revolution the sums granted were voted without any specification as to whether they should be applied to the maintenance of the army, the navy, the civil government, or the household. From that time the expenses of the army and navy were at once separately voted, and charges of civil government have from time to time been removed from the civil list, until, on the accession of William IV., by the separation of the salaries of the judges, the lord-lieutenant of Ireland, the diplomatic salaries and pensions, and the civil-list pensions of previous reigns, the civil-list charge has been properly reduced to the personal and household expenses of the sovereign.

The internal regulations of the royal household may be described under the names of the officers by whose authority they are maintained—the Lord Steward and his Court of Household, and the Lord Chamberlain; two great officers who, from the earliest times, have divided the authority over two distinct branches of the establishment.

The Lord Steward is the chief officer of the household. His authority extends over the offices of treasurer, comptroller, and master of the household, the two former of whom act as his deputies; and all the household officers and servants are subject to his authority, except those of the chapel, the chamber, and the stable. The first two are subject to the Lord Chamberlain, and the latter to the Master of the Horse. The duties of these three high officers are thus described in the *Liber Niger*, Edw. IV.:—*The Steward of the Household* receives his charge and staff from the king himself,—"Seneschall tenez la baton du notre hostiell,"—and by these words is at once constituted Steward of the whole Court of Marshalsea. The secondary estate and rule of the household, under the king, is wholly committed to his charge, and his orders are to be obeyed and observed. Out of the king's presence he is always to be served covered, whatever other great estate may be present. He may permit such to depart as he thinks pleasing to the king. While he is present in court, no new commandments or orders to officers or other persons should be given without his orders first had. In all the household rules and judgments he represents the king; and his staff is taken for his commission.—*The Treasurer of the Household* takes his charge and oath before the king, or his council. He is second estate next to the steward, whose office he represents, and whose privileges he enjoys in his absence. He has the chief charge of the policy and economy of the household, which depend upon his sober and diligent purveyance. It belongs to the treasurer, with the steward and comptroller, to remind the king of his dispositions and purposes, and to make, from time to time provision for the household. To declare what the treasurer's duties are is to say that he should know and overlook every office and officer.—*The Comptroller* takes his charge in the king's presence. He is third in estate in the household after the steward, and by his supervision the treasurer is relieved of many details and accounts of things dispensed, of which he takes the charge. He sees that all goods purveyed for the household are sound and wholesome, and of reasonable price; also that the servants are diligent in their duties, and that their allowances do not exceed their receipts, which are returned into the exchequer. Up to the present time, but little change has taken place in the authorities of these three officers. The treasurer's office appears to have been united with that of the comptroller, and to have been hereditary (stat. 33, Hen. VIII.).—*The Master of the Household* is now under the treasurer, and examines a portion of his accounts, as was formerly done by the cofferer. His chief duties, however, consist more particularly in superintending the selection, qualification, and conduct of the household servants. The three former are always sworn of the Privy Council. They fill political offices, which are held only during the continuance in power of the party to which they belong. The master of the household is appointed during pleasure, and his continuance in office is not dependent upon party. The yearly salaries of these officers at different periods have been as follows:—

					Yearly.		
Under Elizabeth, 1578—							
Lord Steward					L.200	0	0
Treasurer					123	14	0
Comptroller					167	14	0
Under William and Mary, 1689—							
Lord Steward	L.100	0	0	and board wages,	L.1360	0	0
Treasurer (and Cofferer)	223	14	8	...	1076	5	4
Comptroller	107	17	6	...	1092	2	6
Under Victoria, 1856—							
Lord Steward					L.2000	0	0
Treasurer					904	0	0
Comptroller					904	0	0
Master of the Household					1158	0	0

The Court of the Household is held under the Lord Steward and his officers. It is called—

The Court of Marshalsea or Green Cloth, and derived its power from the Common Law, confirmed by several statutes. It had exclusive jurisdiction in the palace of the king, and within the verge, which is defined to include a circuit of 12 miles around. The Court of Marshalsea and of Green Cloth, though exercising at different times very different powers, cannot be described as two separate courts. It is of very ancient constitution, for in the *Household Book* of Edw. IV., ordinances of Hen. I. are quoted as relating to it.

The Steward of the Household is described as "Steward of the whole Court of Marshalsea, of which he is judge of life and limb; and, except those causes, the treasurer, comptroller, cofferer, two clerks of the Green Cloth, and the chief clerk of the enrolment, for any matters else done within the household, or appertaining thereto, they sit with him at the board of doom within the household, that is, the board of Green Cloth in the counting-house, as recorders and witnesses to the truth." The court had, when sitting under the steward as a criminal court, the power to inflict the highest penalties. False compassings and confederacies to destroy the king, or any of the household officers, by the king's servants, was declared felony by 3d Hen. VII., and the trial and judgment were committed to this court. By the 33d Hen. VIII., c. 12, its powers were extended to all treasons, misprisions of treasons, murders, manslaughters, bloodsheds, and malicious strikings, by reason whereof blood is shed, done within any of the royal houses, or houses where the king may be residing, without limitation to offences committed by the servants of the household, with the penalty of death, and forfeiture of lands and goods for all the offences except the malicious striking. For this the penalty was to have the right hand stricken off; and the statute appoints the specific duties of each of twelve of the household servants who are to take a part in this execution, commencing with the chief surgeon, who is to "sear the stump."

Charles I., by letters patent of the sixth year of his reign, in order to remove doubts as to the civil jurisdiction of this household court, and to obviate its frequent removals—for it necessarily followed the court in all its progresses—erected a new court of record called the *Palace Court*, with jurisdiction over all manner of personal actions whatsoever arising between any parties within 12 miles of his palace at Whitehall. The Lord Steward, the Knight Marshal, and the Steward of the Marshalsea, were named as judges, but the Deputy of the Steward of the Marshalsea usually sat alone. Charles II., by a charter of the sixteenth year of his reign, reinstituted the court, which continued to be held under that charter till 1849, when it was abolished by stat. 12 & 13, Vict. cap. 101, on the general establishment of the new county courts for the recovery of small debts.

The extensive criminal jurisdiction of the Lord Steward's court gradually fell into disuse, and the statutes quoted of Henry VII. and Henry VIII. were repealed by 9th Geo. 4, cap. 31. The court became restricted in its functions to the control of the household affairs, and exercised the duties of a board, as it is now alone styled, and no longer those which belong to a court. It took account of all the expenses of the household. It made provision for the household, which in early times comprised the store and purveyance of large supplies of grain, meat, &c., and paid all such charges. It had the good government of the numerous servants and retainers. The steward, treasurer, or comptroller, were required of very special duty to be present daily at the audit of accounts, one or all of them, and to hear complaints, and to correct or appease them after due examination. It was their duty to keep the peace within the palace, and to punish the evil-doers; and for any wrong done to the king's officers or household servants in executing their office or commission, if the offender were the servant of the queen or prince, or any of the judges or lords, he was summoned to answer before the Green Cloth. The usual penalties were,—first, warning in fair manner at the counting-board openly; second, the loss of wages for one month; third, imprisonment for one month; fourth, to be put out of court, and to swear never knowingly to come near it again for ever.

The Lord Chamberlain is at the head of another great branch of the household. He is described (*Lib. Niger*, Edw. IV.), as sitting in the King's chamber, and when it requires for matters to be communed of in the King's Council, then in his own chamber. He was not, therefore, at that time, as has now long been the practice, a member of the Privy Council. "The chamberlain presenteth, chargeth, and dischargeth, all such persons as be of the King's chamber, except all such officers of household, as minister for any victuals for the king's mouth, or for his chamber; for all these take their charge at the *Green Cloth* in the counting-house. He hath the punishment of all those belonging to the chamber for any offence or outrage. The chamberlain taketh his oath and staff of the king, or of his council. He shall at no time within this court be covered in his service." He is "busily to search and oversee the King's chambers, and the estate made therein."

In the present day the duties of the Lord Chamberlain continue nearly those described above. He is an officer of great honour and trust. He is always sworn of the Privy Council. He has control over all the officers and servants of the royal chambers (except the bedchamber), and over the establishment of the chapel-royal, and the physicians, surgeons, and apothecaries of the household; also over the queen's band, and all comedians, trumpeters, and messengers, and all artificers in the queen's service. The performance of stage plays in the metropolis, and wherever there is a royal palace, is illegal, unless the premises in which the performance takes place are licensed by him; nor can any play, or part of a play, be legally acted in any part of Great Britain without his license. It is the Lord Chamberlain's duty to see that persons who wish to be presented to the sovereign at the drawing-rooms and levees are entitled by station and character to that distinction; also to issue, in the Queen's name, invitations to Her Majesty's balls, parties, &c.

The *Vice-Chamberlain* is an ancient officer of the household. The office is shown to have existed in the 13th Richard II. (1389). It is described as of high rank in the reign of Henry IV. The Vice-Chamberlain is now usually sworn a member of the Privy Council. He is the deputy and assistant of the Lord Chamberlain, in whose absence he conducts the Sovereign, and acts with full authority over all the officers and servants subject to his control. Like his principal, he quits office on a change of the government.

The yearly salaries of these officers under different reigns have been as follows:—

Under Elizabeth—							
Lord Chamberlain	200 marks.						
Vice-Chamberlain	100 ...						
Under William and Mary—							
Lord Chamberlain	L.100	0	0	Board wages	L.1100	0	0
Vice Chamberlain	66	13	4	...	492	15	0
Under Victoria—							
Lord Chamberlain					L.2000	0	0
Vice-Chamberlain					924	0	0

In the same book (*Lib. Niger*, Edw. IV.), and in the following order, are also described the officers who formed the chamberlain's branch of the household, with most particular accounts of their places in the house, their allowances, perquisites, and number of attendants. Four bannerets or bachelor knights, called knights of the chamber, twelve knights of the household, a secretary (origin of the secretary of state), with four clerks; four chaplains, four esquires of the body; server of meats, a surveyor of cooks for the king, a wardrober, four gentlemen ushers to pay special attention to strangers; twenty-four yeomen, the watchmen of the previous reign, four yeomen to make beds, an officer of wardrobe of robes, officer of wardrobe of beds, ten grooms of chamber, three pages of chamber; the keeper of the king's jewels, the doctor of physic, the master surgeon, the apothecary, the barber for the king, six henxmen (pages) and their master, and forty esquires of household of different counties, men of education, to give the king counsel.

All the foregoing officers, except the wardrober, either daily or during their rotation of attendance, have their stated allowances; those of higher degree, who take their meals in their own chambers, have livery of "messes of grete mete and roste," wine, torches, candles, faggots, &c.; and those of lesser rank have "etyng in the hall," and take allowances for their chamber at night of wine, ale, bread, candles, and firewood, the quantities being regulated according to the rank of their offices. The number of servants allowed to be brought into the household, and to have livery out of the household, and the allowances which these servants are entitled to receive daily, are also regulated with the same precision.

Then follow the kings of arms, heralds, and pursuivants, whose number is not given. Four serjeants of arms, thirteen minstrels, a wayte, four messengers, priests, dean of chapel, twenty-six chaplains, two yeomen of the chapel, eight children of the chapel, the clerk of the closet, the master of grammar, the officer of vestuary, and the clerk of the crown.

Of the foregoing officers of the Lord Chamberlain's department, the chief, who at present represent their duties, are—*The Lords-in-Waiting*, who attend in rotation, form part of the ordinary court of the Sovereign, and are present on all state occasions. Their appointments are deemed political, and depend upon the existence of the ministry. The *Grooms-in-Waiting* attend in a similar manner. *The Gentlemen Ushers of the Privy Chamber*, who are in constant attendance, and conduct the Sovereign in the absence of the higher officers. The *Gentlemen of the Privy Chamber.* This latter office has become a merely honorary appointment as, of late years, no services have been required. During the present female reign the office of *Groom of the Stole* is in abeyance. His authority in the last reign was exclusive in all matters relating to the bed-chamber. He had no fixed routine of duty, attending only on state occasions. Under his authority were twelve *Lords of the Bedchamber*, officers also in abeyance, and thirteen *Grooms of the Bedchamber.*

The *Yeomen of the Guard* and the *Gentlemen-at-Arms* are the ancient guards of the household. The former corps

Household Royal.

was established by Henry VII. as his body-guard in 1486, and as a royal guard a detachment is still mustered daily in the guard-chamber. The corps now consists of a captain, lieutenant, ensign, four exons, and one hundred yeomen. The yeomen are selected by the commander-in-chief from meritorious men who have served in the army. The captain is usually a peer and a privy councillor, and holds a political appointment dependent upon the government of the day, as does also the captain of the *Gentlemen-at-Arms*. This latter corps was established by Henry VIII. in 1509, and was called the *Band of Gentlemen-Pensioners*, until 1834 when it was re-modelled by William IV., and resumed its ancient title. The appointments are made by the crown on the recommendation of the commander-in-chief, and are restricted to officers of the British army or marines. The corps consists of the captain, lieutenant, standard-bearer, and forty gentlemen, who form the guard to the Queen's person: but their duties now chiefly consist in attendance at drawing-rooms, levees, and state ceremonials.

The *Master of the Horse* is the third great officer of the household, and his office is always described as of great antiquity and trust; but no mention is made of it in the *Household Books* of Hen. VI. or Edw. IV. He is appointed by letters-patent, and has the government and direction of the royal stables, and of all horses and breeds of horses belonging to the crown. His authority extends over all the equerries and pages, grooms, coachmen, saddlers and farriers —and he has the appointment and control of all artificers working for the royal stables. He has the disbursement of the money assigned for the expenses of this department of the household, and exhibits his accounts for the audit of the Green Cloth. He alone is privileged to use the royal horses and carriages, and upon state occasions he rides next to the Sovereign. The *Clerk-Marshal and Chief Equerry* has authority next to the Master of the Horse, and has power to act for him in all matters when absent. He attends the Queen on her rides and upon all state occasions. The four equerries, and four pages of honour, are the remaining head officers. They are the personal attendants upon the Queen, and form part of the state of her court. On attaining a suitable age the pages receive a commission in the Guards without purchase. The *Master of the Buckhounds* is another ancient office connected with this part of the household. His duties seem now to be restricted to the management of the royal hunt. The offices of the Master of the Horse, the Chief Equerry and the Master of the Buckhounds, are dependent upon the duration of the political party in power.

The yearly salary of the Master of the Horse under different reigns has been as follows:—

Under Queen Elizabeth	1000 marks
Under William and Mary	L.1200
Under Victoria	2500

The *Ladies of the Household* fill a more important rank in the court of a female sovereign. The *Mistress of the Robes* is at the head of this part of the household. Her office is ancient and of high dignity. She has the superintendence of all duties belonging to the bedchamber, within which the Lord Chamberlain has no authority. She regulates the rotation and times of attendance of all the ladies. She has the custody of the robes; and on state occasions sees that the ceremony of robing the Queen is properly performed. She rides in the same carriage with the Queen on state occasions. The *Ladies of the Bedchamber* are the personal attendants upon the Queen, and form part of her court on state occasions. There are now eight, and two extra. The *Bedchamber Women*, also eight, and one extra, are subordinate to them. The *Maids of Honour*, eight, are the immediate attendants upon the Queen. They are on duty in rotation, and accompany Her Majesty upon all occasions.

The yearly salaries attached to each of the foregoing offices are as follow:—

Lords-in-Waiting	L.703
Grooms-in-Waiting	335 10s.
Groom of the Stole (in abeyance)	2000
Lords of the Bedchamber (in abeyance)	1000
Grooms of the Bedchamber	500
Yeomen of the guard—	
Captain	1000
Lieutenant	500
Ensign	300
Exons	150
Yeomen	60
Gentlemen-at-arms—	
Captain	1000
Gentlemen-at-arms—	
Lieutenant	L.500
Standard-bearer	310
Clerk of the Cheque	120
Gentlemen	70
Master of the Horse	2500
Clerk-Marshal, &c.	1000
Equerries	700
Pages	200
Master of the Buckhounds	1700
Ladies of the Household—	
Mistress of the Robes	500
Ladies of the Bedchamber	500
Bedchamber Women	300
Maids of Honour	400

The household officers described in the foregoing are distinct from a class of hereditary officers of great consideration and rank, who on certain state ceremonies perform duties to the sovereign. (S. R.)

Houssa.

HOUSSA is the name of an extensive portion of Central Africa, which, along with Bornou, bears the general name of Soudan, or Land of the South. It consists of various petty kingdoms or states, which occupy territory stretching E. and W. from the upper course of the Yeou nearly to the Niger, the boundaries of which on the S. and N. and W. have now for the first time been determined by Dr Barth. This region appears in several respects to be superior to the countries on either side of it. It is less sultry, an advantage which it probably owes to its higher elevation. The face of the country bears marks of greater cultivation, the fields being covered with large crops of several kinds of Indian corn, two of which are annually produced; and, to prevent the grain from being destroyed by insects, it is secured in granaries raised on poles. The soil is well watered by the rivers Sokoto, Mariadi, Zyrmie, Bugga, Zoma, and others, which, with several tributaries, flows westward to join the Niger. On its eastern quarter it is traversed by the Yeou, and on its southern by the Benneh or Chadda. Besides these natural supplies of water, artificial irrigation is diligently practised.

The dominant people in Houssa are the Fellatas, this country forming, in fact, a considerable portion of the empire of Sokoto, which again comprises the eastern part of the Fellata dominions. The following provinces constituting Houssa are, according to Dr Barth—

1. Kano, with the governor or sultan of Osman Ben Ibrahim Dabo. Important on account of the market, which yields 10,000 cowries daily for the household of the great sultan at Sokoto. The military power consists of 7000 horse.
2. Boshi, or Bautschi, S.E. from Kano, with the capital Yakoba, the most powerful province after Kano. The sultan, Ibrahim Ben Yakúba, has a force of 2000 horse, and his troops of archers which are numberless, besides their being known as the best in Soudan.
3. Zegzeg, a province of great extent S. of Kano. The sultan, Mohammed Sani, resides at Zaria, and has about 2000 horse, as well as numbers of archers.
4. Khadedsha, or Hadija, a small province E. from Kano, with the sultan Kammedu, having a force of about 2000 horse.
5. Katagum, S.E. from Kano. The sultan, Abd-er-Rahmán, is said to bring 1500 horse into the field.
6. Katsena, N.W. of Kano, with the residence of the same name. Owing to its vicinity to the hostile countries of Mariadi and Gober, this province has greatly declined in power; the sultan, Mohammed Bello Ben Mallem Romáro, has a force of not much more than 1000 horse.
7. Daura, E. of Katsena, a province greatly devastated. The freebooting governor, Mohammed Bello, though he has but 400 horse, is feared by all his neighbours.
8. Zanfara, a large province W. from Katsena, with Ahmedu the sultan, who resides at Bakura, and has a force of 3000 to 4000 horse in command.

9. Gober, to the N.E. of Sokoto, and adjoining the Desert. The residence of the sultan Wurno belongs to this province, and forms the southernmost boundary.
10. Kebbi, the eastern portion of it, comprising the capital of the eastern Fellata empire, Sokoto.

Kano, the capital of a province of the same name, and the principal commercial city of Houssa, is situated in N. Lat. 12. 0. 19., and E. Long. 8. 30. It may contain between 30,000 and 40,000 inhabitants, of whom a great proportion are slaves. This number is exclusive of strangers, who crowd thither during the dry months from all parts of Africa. The city is of an irregular oval shape, about fifteen miles in circumference, and surrounded by a clay wall thirty feet in height, having a dry ditch on both sides of it. There are fourteen gates made of wood, and covered with sheet iron, and these are regularly opened and shut at sunrise and sunset. A platform inside, with two guardhouses below it, serves to defend each entrance. The houses within the walls do not occupy more than one fourth of the ground inclosed, the remaining space being laid out in fields and gardens. The city is almost divided into two parts by a large morass, which stretches from E. to W. This swamp is crossed by a small neck of land, which is overflowed during the rainy season, but in the dry season the market is held upon it. On account of this morass, and also of the many pools of stagnant water made by digging clay for building houses, the city is rendered very unhealthy. Captain Clapperton thus describes the houses of Kano.

"They are built of clay, and are mostly of a square form, in the Moorish fashion, with a central room, the roof of which is supported by the trunks of palm-trees, where visitors and strangers are received. The apartments of the ground-floor open into this hall of audience, and are generally used as store-rooms. A staircase leads to an open gallery overlooking the hall, and serving as a passage to the chambers of the second story, which are lighted with small windows. In a back court-yard there is a well and other conveniences. Within the inclosure in which the house stands, there are also a few round huts of clay, roofed with the stalks of Indian corn, and thatched with long grass. These are usually very neat and clean, and of a much larger size than those of Bornou. The governor's residence covers a large space, and resembles a walled village. It even contains a mosque, and several towers three or four stories high, with windows in the European style, but without glass or framework. It is necessary to pass through two of these towers in order to gain the suite of inner apartments occupied by the governor."

The great market, as already observed, is held upon the neck of land which intersects the morass. Here streets consisting of sheds or stalls of bamboo are regularly arranged, different places being allotted to those who traffic in different commodities. The latter consist of cattle, vegetables, fruits, the fine cotton fabrics of the country, goora or kolla nuts, which are called African coffee, and crude antimony, with which every eyebrow in Houssa is dyed. The Arabs also dispose of sundry commodities, such as various dresses. The slaves, who constitute the staple article of trade, have a special market appropriated to them, consisting of two long ranges of sheds, one for males and the other for females. Here these poor creatures, drawn up in regular array, and dressed in attractive attire, are inspected and scrutinized by purchasers, in much the same manner as horses are in the cattle-markets of this country. The market of Kano is under the superintendence of a sheik, who regulates the police, and is said also to possess the exorbitant power of fixing the prices. The medium of exchange consists of the small shells called cowries, four hundred and eighty of which make a shilling, so that paying a large sum is here rather a tedious process. Kano is celebrated all over Central Africa for the dyeing of cloth, for which process there are numerous establishments. Some ingenuity is displayed in the manufacture of leathern jars, which are fashioned upon a clay mould out of the raw hide. The inhabitants are also acquainted with the art of tanning. The negroes here are very polite and ceremonious, especially to those advanced in years. A part of the city is appropriated to the use of those who are afflicted with blindness, which is a prevalent disease.

Adjoining the province of Kano on the E. there is a portion of territory called Katagum, which in Captain Clapperton's time was able to send into the field 4000 horse and 20,000 foot, armed with bows, swords, and spears. The city is built in the form of a square, the sides facing the cardinal points of the compass, with four corresponding gates, which are regularly opened and shut like those of Kano. It is defended by two walls, which have ditches on each side, and one between them. The governor and principal inhabitants have houses made entirely of clay. They are flat-roofed, and sometimes consist of two stories, with square or semi-circular openings for windows. The city may contain from 7000 to 8000 inhabitants. There are other towns comprised within the boundaries of this province, but none requiring particular description. Many parts of Katagum are highly cultivated, and laid out in plantations of cotton, tobacco, and indigo, which are separated from one another by rows of date-trees, and shaded by large umbrageous trees.

The next considerable town is Sokoto, situated nearly at the western extremity of Houssa. The country which lies between Kano and Sokoto is remarkably fine, and under high cultivation. It is diversified with forests of noble trees, and various rivers and streams, and traversed by picturesque ridges of granite, amongst which villages are romantically situated.

Sokoto stands in N. Lat. 13. 4. 52., and E. Long. 5. 20. "It occupies," says Captain Clapperton, "a long ridge which slopes gently towards the N., and appeared to me the most populous town I had visited in the interior of Africa; for, unlike most other towns in Houssa, where the houses are thinly scattered, it is laid out in regular well-built streets. The houses approach close to the walls, which were built by the present sultan in 1818, after the death of his father; the old walls being too confined for the increasing population. There are two large mosques, including the new one at present building by the Gadado, besides several other places for prayer. There is a spacious market-place in the centre of the city, and another large square in front of the sultan's residence. The dwellings of the principal people are surrounded with high walls, which inclose numerous coozees and flat-roofed houses, built in the Moorish style, whose large water-spouts of baked clay, projecting from the eaves, resemble at first sight a tier of guns. The inhabitants are principally Fellatas, possessing numerous slaves. Such of the latter as are not employed in domestic duties reside in houses by themselves, where they follow various trades; the master, of course, reaping the profit. Their usual employments are weaving, house-building, shoemaking, and iron work; many bring firewood to the market for sale. Those employed in raising grain and tending cattle, of which the Fellatas have immense herds, reside in villages without the city. It is customary for private individuals to free a number of slaves every year, according to their means, during the great feast after the Ramadan. The enfranchised seldom return to their native country, but continue to reside near their old masters, still acknowledging them as their superiors, and presenting them yearly with a portion of their earnings. The trade of Sokoto is at present inconsiderable, owing to the disturbed state of the surrounding country. The necessaries of life are very cheap; butcher-meat is in great plenty, and very good. The exports are principally civet and blue check *tobes* called *sharie*, which are manufactured by the slaves from Nyffi, of whom the men are considered as the most expert weavers in Soudan, and the women as the best spinners. The common imports are brought from the borders of Ashanti; and coarse calico and woollen cloth, in small quantities, with brass and pewter dishes, and some few spices, from Nyffi. The Arabs, from Tripoli and Ghadamis, bring unwrought silk, ottar of roses, spices, and beads. Slaves are both exported and imported. A great quantity of Guinea corn is taken every year by the Tuaricks, in exchange for salt. The market is extremely well supplied, and is held daily from sunrise to sunset. On the N. side of Sokoto there is a low marsh, with some stagnant pools of water, between the city and the river; this, perhaps, may be the cause of the great prevalence of ague, as the city stands in a fine airy situation."

Subsequently to the writing of the above description, nearly two-thirds of the city was destroyed by a conflagration; but when Clapperton visited it a second time, it had been rebuilt, in a manner so closely resembling what it had formerly been, that little alteration could be perceived. The palace, or house of the sultan, forms a sort of inclosed town, with an open quadrangle in front. A painted and ornamented cottage constitutes the hall of audience. Sokoto even then was on the decline, on account of the residence of the court having of late been transferred to Magaria.

According to the more recent information as supplied by Dr Barth, the town of Wurno, previously quite unknown, has become the capital instead of Magaria.

Wurno is situated 15 geographical miles N.E. from Sokoto, and is quite a new town, having been founded by Sultan Bello in 1831. It lies on a gentle eminence in a bend of the River Rima, which here flows towards Sokoto. It contains at present 12,000 to 13,000 inhabitants, among which are the most opulent inhabitants of Sokoto, who left that town when Wurno was founded. As to the market, however, that of Sokoto is still superior to that of Wurno, and forms one of the best provided markets in all Central Africa. Regarding the number of inhabitants, Sokoto is also much above Wurno,—still possessing, as it does, 20,000 to 22,000 souls. Dr Barth resided for upwards of a month at Wurno, where he was very kindly received.

Sokoto is described by Dr Barth as forming nearly a regular square, and having eight gates, not twelve, as formerly supposed. Dr Barth found the house of the gedádo, Clapperton's old friend, who died only two years previously, while that of the Sultan Bello was almost in ruins. The best inhabited quarter of the town, at present, is that round the large residence of Hammédu, the valiant son of Atíku, the brother and successor of Bello, during whose reign the roads were so safe that a single traveller could go from Sokoto to Kano without the least danger, whereas they have since become so insecure that almost all communications with Kassena and Kano have ceased, and the Arab traders have discontinued their visits, so much so, that at present not a single Arab lives either at Sokoto or Wurno; the commerce of those places with the Mediterranean shores is now in the hands of the people of Air and Ghat, who arrive annually with the large salt caravans of the Hésan and Kelgeres. Sokoto has a mixed population, the Zoromana forming the chief portion of the inhabitants. They are, unlike the tribes of pure Pullo or Fellan origin, very industrious, and are excellent workmen in leather, iron, and gebbega or cotton-stripes. The articles of iron made at Sokoto are the best in all Soudan; and Dr Barth purchased some specimens of beautiful workmanship. The Zoromana are the principal inhabitants of the town, while the Syllebana, a very interesting tribe, different from, but united with the Fellatas from time immemorial, inhabit the villages round the town. There are also a great many Nyffi (or Nufi), and Yariba (or Yoriba) people living in Sokoto.

The same recent traveller describes the country in the vicinity of Wurno and Sokoto as a tableland of sandstone formation, the more elevated portions being chiefly cultivated with dhurra, while the faddamas or valleys, which are greatly inundated during a portion of the year, form excellent ground for the cultivation of rice and cotton, besides which, *rogo*, a large palatable root, is extensively grown. The country in the immediate vicinity of Wurno is very bare of trees; but in other parts there are plenty of *doom* trees, *kurna*, tamarind, and *gonda*.

The countries of Guber and Zamfra or Zanfara are inhabited by a rude and warlike race, who have sometimes assumed authority over Houssa, and are at present, or were lately, in open rebellion against Sokoto. Coonia, the capital of Guber, was a strongly fortified place, and in 1829 repulsed the whole military force of Houssa, consisting of 50,000 or 60,000 men, but has been since, according to Dr Barth, entirely destroyed. Zirmie occupies a peninsula formed by a small river, which has here very high and steep banks covered with mimosas and prickly bushes, through which a narrow path winds to the gates. It is surrounded with a clay wall and a dry ditch. The governor of this stronghold bears the character of a freebooter, and the inhabitants, whom Clapperton represents as having a reckless independent look, are esteemed the greatest rogues in all Houssa. Runaway slaves from all quarters make Zirmie an asylum, where they are always well received.

To the N.N.W. of Kano lies the considerable province of Kashna or Kassina, which at one period held supreme sway over all Houssa, and which has recently shaken off the yoke of Sokoto. Kashna, the capital, is situated in N. Lat. 12. 59., on a ridge of sienite, one of a number of ridges of this rock which run from N.N.E. to S.S.W. The walls are of clay, and very extensive; but, as in the case of Kano, the houses do not occupy above one-tenth of the ground inclosed, the rest being laid out in fields, and covered with wood. The houses are mostly in ruins, the principal commerce of the country having been transferred to Kano since the Fellata power became predominant. Notwithstanding its abject state, it has nevertheless a considerable trade, which is carried on with the Tuaricks, or with caravans coming across the desert by the route of Ghadamis and Tuat. The manufactures of Kashna are chiefly of leather, such as water-skins, red or yellow cushions, bridles of goat-skin, and hides. There is likewise some trade in fruits, such as figs, melons, pomegranates, and limes.

To the S. of Sokoto and Kano lies the country of Zegzeg, one of the finest in all Africa, and the most extensive province in Houssa. It is bounded on the E. by Kano, on the S.E. by Boshi, on the S. by a mountainous tract inhabited by pagans, on the S.W. by Nyffi, and on the N. and W. by Guari and Kashna. Travellers represent Zegzeg as resembling in appearance the finest parts of England, being beautifully variegated with hill and dale, over which are spread rich pastures and extensive fields, yielding plentiful crops, particularly of rice. Zaria, the capital, is situated in N. Lat. 10. 59. and about E. Long. 8. 0. It occupies a great extent of ground, the houses being detached, or rather clustered together in small villages, which are separated from each other by corn fields, and even woods. The whole is surrounded with high clay walls, and the population has been estimated at about 50,000. To the S. of Zegzeg, the country, though diversified by rising grounds, is fertile and well cultivated, and contains a number of considerable towns. Lander describes Cuttup as consisting of "nearly 500 villages almost joining each other, occupying a vast and beautiful plain, adorned with the finest trees. Among these, the plantain, the palm, and the cocoa-nut tree were seen flourishing in great abundance, and the aspect of the country strikingly resembled some parts of Yariba. A considerable traffic is carried on here in slaves and bullocks, which are

Houssa.

alike exposed in the daily market. The bullocks are bred by the Fellatas, who reside here for no other purpose. Among the other articles brought here for sale, are red cloth, gum, salt, goora-nuts, trona, beads, tobacco, native cloth, rings, needles, cutlery, honey, rice, and milk; people from the most distant parts resorting hither in vast numbers." To the south of this place stretch a range of hills, which, Lander was told, were inhabited by a ferocious race of *yam-yams* or cannibals, who a short time previously had killed and eaten a whole caravan of people. In a country fertile, but rocky, is situated Dunrora, a town containing about 4000 inhabitants.

In the western tracts of Houssa there are few towns of any importance: some were visited, and have been described by Captain Clapperton. After leaving Boogawa, a small town in the province of Katagum, and passing first through a thickly-wooded tract, and then over an open, well cultivated country, this traveller reached Katungwa, a walled town. A range of low rocky hills was seen stretching nearly S.W., called *Dooshee* (the rocks), from which a large town takes its name. These were the first rocks that had occurred after leaving the southern borders of the Great Desert, the whole country thus far being alluvial clay. Near the extremity of the Dooshee Hills is situated Zangeia, within the walls of which town there is a ridge of loose blocks of stone connected with the range. These masses of rock are about 200 feet in height, and give a romantic appearance to the neat huts clustering round the base, and to the fine plantations of cotton, tobacco, and indigo, and the rows of date and other trees. From the extensive walls which remain, Zangeia must have once been a very large town. Now, however, it consists merely of a collection of thinly scattered hamlets. The country between this place and Kano is highly cultivated, and beautifully diversified by hill and dale. Captain Clapperton passed several walled towns, the principal of which was Girkwa. As in the other towns already described, the houses here are in groups, with large intervening vacancies. The disproportion in the size of the walls of towns and the number of houses, to the amount of inhabitants, which is exhibited in many parts of Houssa, is to be accounted for by the usurpation of the country by the Fellatas, who generally massacred the former occupants, or carried them away captives. To complete our description of Houssa, it will be necessary to give an account of this singular people, who are gradually extending their authority over Central Africa.

By the most correct accounts, it would appear that the Fellatas are an off-shoot from the Foolahs of Western Africa, and may be identified with them. They are a mixture of Moors, Arabs, Berbers, and probably other races of men. They are much superior to the native negroes, with whom they very rarely mix their blood. Captain Lyon, speaking of the Fellatas, observes, "their complexion being of a much lighter hue than that of the other tribes, they call themselves white; their colour resembles that of our gypsies in England. Many female slaves are brought to Mourzouk from their nation, and are very handsome women." Other observers describe their complexion as being very dark, and of a shade intermediate between that of the deepest African and the Moors. The fact seems to be, that their colour varies in a very remarkable manner, from being nearly white to nearly black. Both men and women pay considerable attention to their dress, which amongst the wealthy inhabitants is rather showy. In their domestic habits they are regular, orderly, and cleanly, and the slaves are generally well treated. The Mohammedan is the predominant religion, and considerable attention is paid to keeping up an appearance of it. Prayers are regularly said five times a day in the Arabic language, which both the male and female children of the better sort of Fellatas are taught to read and write. Their marriages are celebrated without any pomp or noise, and such contracts are of a less arbitrary nature than we find them to be amongst the inferior races of mankind. Captain Clapperton makes the following remarks regarding Houssa:—"The government of the Fellatas in Soudan is in its infancy. The governors of the different provinces are appointed during pleasure; and all their property, on their death or removal, falls to the sultan. The appointment to a vacancy is sold to the highest bidder, who is generally a near relation, provided that his property is sufficient to enable him to bid up to the mark. All the inferior offices in the towns are sold in like manner by the governors, who also succeed to the property of those petty officers at their death or removal. A great deal of marketable property is claimed by the governor, such as two-thirds of the produce of all the date-trees and other fruit-trees, the proprietor being allowed only the remaining third. A small duty is also levied on every article sold in the market; or, in lieu thereof, a certain rent is paid for the stall or shed. A duty is also fixed on every *tobe* that is dyed blue, and sold. On grain there is no duty. Kano produces the greatest revenue that the sultan receives; it is paid monthly, in horses, cloth, and cowries. Adamowa pays yearly in slaves; Yacoba in slaves and lead ore; Zegzeg in slaves and cowries; Zamfra the same; Hadeja and Katagum in horses, bullocks, and slaves; Cashna in slaves, cowries, and cloth; Ader, or Tadela, in bullocks, sheep, camels, and a coarse kind of cotton cloth, like what is called by us a counterpane." Of the number of negroes and Fellatas who inhabit the country of Houssa no correct idea can be formed. Much additional and more precise information on these countries may be expected from the pen of Dr Barth, that energetic traveller, who has so thoroughly explored these regions. (A. P.)

Houston
||
Hoveden.

HOUSTON, a city of Texas, United States of North America, capital of Harris county, and the second commercial city in the state. It is situated on Buffalo Bayou, at the head of its steamboat navigation, and 45 miles above its mouth in Galveston Bay. It is the principal shipping port for the cotton, sugar, and maize of the adjacent counties. Pop. (1853) estimated at 6000.

HOVEDEN, ROGER DE, an ancient English chronicler, was a native of Yorkshire, and is believed to have been born in the town of Hoveden or Howden, from which he took his name. The dates of his birth and death are not known with certainty, but he seems to have been born about the middle of the twelfth century, and to have lived some years into the thirteenth. He was well acquainted with civil law, and his knowledge of canon law recommended him to Henry II., who employed him to inspect the houses of the religious orders, and keep watch over such of their revenues as fell in to the king on the death of any of the superiors. Taking up the narrative of his *History* at the year 732 (the point at which that of the venerable Bede comes to a close), Hoveden brings it down to 1202, the third year of the reign of King John. By far the largest portion of the work is occupied with the reigns of Henry II., Richard, and John. The historical details of this period are very fully given, and are illustrated by a large number of letters of kings, popes, and leading nobles. The writing itself is the most condensed to be found in any of our old chronicles, and is in fact carried to such an extreme, that the chronicler never stops the dusty march of his narration to indulge in a single reflection, or indicate his own opinion by a solitary adjective. His strict accuracy and fidelity, however, are unanimously attested by all the best antiquaries. So high, indeed, did his character for these qualities stand in his own times, that Edward I. is said to have sought out his history with a view of settling, on its authority, the justice of his claims to homage from the king of Scotland. Hoveden's *History* is published in Sir Henry Savile's collection of the *Scriptores post Bedam*, and was reprinted at Frankfort in 1601. A translation of it by H. F.

Riley, B.A., forms vols. xx. to xxiii. of Bohn's *Antiquarian Library*.

HOVELLERS, The, a hardy and useful race of boatmen residing principally at Deal, Dover, Ramsgate, and Margate. They are distinct from the ordinary maritime population, and annually save a large amount of property and many lives by their skill and seamanship. They have different kinds of boats, according as they have to land passengers or help ships in distress. An important part of their task is that of taking out anchors and chains to ships in stormy weather. A service of this kind done one day may be rewarded with L.50, and next day the same service with L.500. The reason of the difference is, that while in fair weather the hovellers are paid for their labour, they are paid, in bad weather, for the risk they run, according to a systematic principle introduced by the late Henry Dove, Esq., R.N. of Margate. The awards are determined by a commission of naval officers appointed for the purpose.

HOWARD, Charles, *Lord Howard of Effingham* was the son of Lord William Howard, and grandson of Thomas Howard, second duke of Norfolk. Under his father, who was lord-high-admiral of England, he served with much distinction both by land and sea; and when the Spanish Armada was approaching the shores of England in 1588, he was himself promoted to the office which his father had so ably filled. It was mainly owing to his valour and nautical skill that that mighty armament was foiled, and Elizabeth evinced her sense of his services, by granting him a life-pension. In 1596, he held the joint command along with Essex of the English expedition against Cadiz, and on returning home was again rewarded for his services by the queen, who created him Earl of Nottingham. This act of Elizabeth's is the more creditable to her, that Essex, piqued at not being entrusted with the supreme command, had ungenerously tried to poison her mind against one of her most able and faithful servants. In 1599, when danger again threatened on the side of Spain, and Essex's conduct in Ireland seemed to indicate rebellion, Howard was made lieutenant-general of the kingdom, with the command-in-chief of all the forces, naval and military. In the six weeks during which he held this office, he crushed his old rival and brother-in-arms, who had raised the standard of revolt in Ireland; but instead of trampling upon his fallen foe, he treated him with a noble generosity and forbearance, of which that foe had shown himself little worthy. Elizabeth's death made no change in Howard's position at court. Her successor frequently availed himself of his services in delicate and important affairs. Some years before his death, Howard resigned his office of lord-high-admiral in favour of Villiers Earl of Buckingham, receiving in exchange a pension of L.1000. He died, December 14, 1624, in the eighty-seventh year of his age, after one of the most useful and honourable careers that ever fell to the lot of an English seaman to pass through.

Howard, *Henry*, Earl of Surrey, one of the most gallant and accomplished of English nobles, and the first of our poets who composed in blank verse, was the eldest son of Thomas the third Duke of Norfolk. The exact date and place of his birth have not been ascertained, but the former is usually assigned to the year 1517. Of a family illustrious for rank, fortune, alliances, and public services, Surrey was early introduced to court, and he formed an intimacy, which soon ripened into a close and tender friendship with the king's natural son, Henry Fitzroy, Duke of Richmond. While yet a boy, we find Surrey in attendance at court as cup-bearer to the king. In 1532, along with his young friend Richmond, he accompanied the sovereign to Boulogne, and in the following year he assisted as one of the sword-bearers at the marriage of Henry with Anne Boleyn. About this period, or even earlier, Surrey was affianced to the Lady Francis Vere, daughter of the Earl of Oxford, while Richmond was in like manner contracted to the Lady Mary Howard, Surrey's sister. The actual marriage of Surrey did not take place till 1535, and that of Richmond was prevented by his premature death, in July 1536. Previous to this time Surrey seems to have been enamoured of a certain Lady Geraldine, who has puzzled his biographers, and served as the groundwork of a series of romantic fictions. Some of the love sonnets of the noble poet may be purely fanciful imitations of Petrarch, in accordance with the taste and chivalrous gallantry of the age, but in one he gives a minute account of the lady of his affections:—

> "From Tuscane came my lady's worthy race;
> Fair Florence was some time her ancient seat:
> The Western Isle whose pleasant shore doth face
> Wild Camber's cliffs first gave her lively heat;
> Fostered she was with milk of Irish breast;
> Her sire an earl, her dame of prince's blood,
> From tender years in Britain did she rest
> With king's child, where she tasteth costly food.
> Hunsdon did first present her to mine eyen,
> Bright is her hue, and Geraldine she hight.
> Hampton me taught to wish her first for mine,
> And Windsor, alas! doth chace me from her sight."

This array of biographical particulars indicates a real personage, and Horace Walpole set himself to prove that the lady was a daughter of Gerald Fitzgerald, Earl of Kildare, whose family is said to have been descended from one of the Dukes of Tuscany. Various circumstances concur to establish this theory, but the lady could only have been a child when Surrey wrote his sonnet, unless we suppose that his attachment had, contrary to good faith and true knighthood, taken place after his marriage. Founding upon this sonnet, Tom Nash, one of the most lively and unscrupulous satirists and miscellaneous writers of the reign of Elizabeth, put forth a singular romance, the pretended journey and adventures of Surrey in Italy on a visit to Florence, the assumed birth-place of his Geraldine. Nash's invention imposed upon Drayton, and being adopted by Anthony à Wood in his *Athenæ* (with sundry additions, and Nash's authorship concealed), was continued as a genuine narrative by Walpole, Warton, and others. According to this historical romance, Surrey travelled like an Amadis, proclaiming the charms of his mistress, and prepared to defend her beauty in the spirit of knight errantry. On his way to Florence he passed a few days at the emperor's court, and there met Cornelius Agrippa, a celebrated adept in natural magic, who, in his mirror of glass, showed him the lively image of his Geraldine, "weeping on her bed, and resolved all into devout religion for the absence of her lord." Inflamed by the spectacle, Surrey hastened to Florence, and published a defiance to all knights and lovers, whether Christian, Jew, Turk, Saracen, or cannibal, who should presume to dispute the superiority of his Geraldine's beauty. The challenge was accepted, the Grand Duke permitting the combat, and opening the lists to all nations, and Surrey, of course, proved victorious. The shield which he presented to the duke before the tournament began, being preserved by the Norfolk family, and engraved by Vertue! The whole of this story—the continental journey, magic mirror, and tournament, was the invention of Nash, and is related in his *Life of Jack Wilton*, published in 1594. The literary fraud remained undiscovered till 1810, when Alexander Chalmers, in his edition of the *English Poets*, partially separated the truth of Surrey's history from the fable that had been blended with it, and Dr Nott, in his *Memoir of Surrey*, completed the detection. At the time of the pretended journey, the noble poet was in England anticipating the birth of his son, who was born on the 10th of March 1536. In May, of this year, the trial of Anne Boleyn took place, and Surrey was present as Earl Marshal, in the room of his father, who presided as Lord Treasurer. In October he obtained the honour of knighthood from the king. At all the pageants and tournaments of the court, he was a conspicuous actor, and when war with France was threatened, we find him no less prominent in important public service. In 1540 he was joined in a commission with Lord Russell and the Earl of Southampton to visit the English Pale at Guisnes, and place the defences in proper order. He returned before Christmas. In the following year an incident is related, which, though involved, like other events in his career, in some obscurity, seems to illustrate at once his personal influence and magnanimity of character. Sir Edward Knyvett, a person high in court favour, assaulted Surrey's friend and attendant, Thomas Clere, having struck him within the precincts of the palace. The indignity would probably have been passed over as inflicted only on a subordinate, but Surrey took it up warmly, and succeeded in bringing Knyvett to trial, the result of which was, that the knight was convicted and sentenced to lose his right hand. At this point Surrey again interposed. The public trial and conviction he deemed sufficient punishment, and at his intercession the sentence was remitted. In 1542, the king conferred upon Surrey the distinction of the order of the garter. He seems, however, to have fallen into temporary disgrace the same year, in consequence of having quarrelled with, and challenged a certain John-à-Leigh of Middlesex. His conduct in this matter must have been violent and blameable, for he was committed to the Fleet, and only obtained his release after making a humble supplication to the privy council (in which he speaks of the "fury of reckless youth," and promises to "bridle in his heady will"), and by entering into recognizances to keep the peace to John-à-Leigh and his friends. A better field for his impetuosity and courage was soon opened up. War with Scotland was declared. Henry, indignant at his nephew, James V., who had failed to meet him at a conference appointed to be held at York, and who had otherwise offended the imperious monarch, ordered the Duke of Norfolk to proceed to the borders with a force of 40,000 men to chastise and lay waste the country. Surrey, attended by Thomas Clere, accompanied his father on this expedition, and the English army unresisted, ravaged the border districts, burning two towns and twenty villages on the banks of the Tweed. What part Surrey took in this affair, or what command he held, is not stated, but in his epitaph on Clere, he mentions that his follower, tracing the steps of his lord, "saw Kelsal [Kelso] blaze." The short and destructive *raid* was over by the end of November 1542. On the 1st of April following, Surrey is ascertained to have been in London, the records of the privy council of that date furnishing another instance of his "heady will." It appears that with two companions, Wyatt and Pickering, he was summoned to the council on a complaint by the mayor, recorder, and aldermen, of the city, charging him with having, "in a lewd and unseemly manner," walked in the night about the streets, breaking the windows of the citizens with his stone-bow; and farther, that he had been guilty of eating flesh during the time of Lent. The first and most serious of these offences he did not attempt to deny: he acknowledged that he had "very evil doings therein;" but touching the eating of flesh, he alleged a license, "albeit he had not so secretly used the same as appertained." He was sent to the Fleet for a month; and he took revenge on the citizens, by inditing a poetical satire against them, in which he gravely alleges, that he woke the sluggards with his bow as a reproof to them for their dissolute life and sins—

"The which by words since preachers know
What hope is left for to redress,
By unknown means it liked me,
My hidden burthen to express."

This must be taken as ironical; but throughout the whole satire Surrey appears in the character of a devout and indignant denouncer of the vices of "false Babylon," on which he says the martyrs' blood calls for justice, and the Lord would hear their desire! We cannot but think that there was something more in this case than mere riotous excess and youthful folly. But Surrey was soon called off by military service from any further display of his unruly piety. War had been declared against France, and Surrey joined the auxiliary army under Sir John Wallop, encamped before Landrecy. He applied himself diligently to the study of military fortifications and tactics, and one day, when visiting the trenches, he made a narrow escape from a piece of ordnance shot towards him. On the approach of winter the siege of Landrecy was raised, the army went into quarters, and Surrey returned to England. Next summer he was again in the field, holding the important post of marshal of the vanguard commanded by his father. The troops under Norfolk and Surrey besieged Montreuil, but were inadequately supported, owing chiefly, it is said, to the jealousy and enmity of the Earl of Hertford, who kept back supplies; but there was no lack of military skill or bravery. Surrey distinguished himself by daring expeditions against the enemy, and on an attempt to storm the town he effected a lodgement within the gates, but was dangerously wounded and carried off by his attendant Clere. In this service Clere himself received a hurt which ultimately proved fatal.

"At Montreuil gates, hopeless of all recure,
Thine Earl, half dead, gave in thy hand his will,
Which cause did thee this pining death procure."

The English were compelled to raise the siege of Montreuil. The Dauphin was approaching with an army of 60,000 men, and Norfolk's vanguard, though strengthened by reinforcements, was unable to cope with such a force. A retreat was resolved upon, which was ably conducted by Surrey as marshal of the camp. Boulogne had capitulated to Henry in person, and it was necessary to guard and maintain an acquisition so dearly purchased and highly valued. In the summer of 1545 Surrey again sailed for France, as commander of a body of 5000 men raised and equipped for a new expedition. He was shortly afterwards appointed governor or king's lieutenant of Boulogne; and both in his plans of defence, and in operations in the field, he fully sustained his reputation. One great effort, however, unfortunately proved a failure. He attempted to intercept a convoy of provisions for the enemy near St Etienne, but the defence was obstinate, and one of Surrey's attacking columns of infantry fled back in a sudden panic, which threw the army into disorder, and the day was lost. This disastrous affair was seized upon by Lord Hertford to incense the king against Surrey, and within a few months he was recalled, his successful rival being appointed the king's lieutenant-general. Prudence was never one of the virtues of Surrey, and his indignation at the intrigues of Hertford was openly and fiercely manifested, accompanied by expressions importing that he would be revenged in the next king's reign. The jealousy of Henry was roused by these declarations, and Surrey was sent a prisoner to Windsor Castle. He succeeded, however, in softening if not removing the royal displeasure, and in August of the same year he is again seen in attendance at court. This glimpse of favour soon vanished never to be renewed. On the 12th of December Surrey was arrested and committed to the Tower, and on the same day his father was also consigned to the Tower, each being ignorant of the other's fate. There can be no doubt that it is to the Hertford faction that we must attribute this decisive step. The king was known to be dying, and Hertford, as uncle of the heir to the throne, aspired to be protector of the kingdom during the minority of his nephew. The family of Norfolk stood between him and his ambition. The Duke was head of the Roman Catholics, and the most opulent and powerful nobleman in the kingdom. His son, the Earl of Surrey, was likely to extend and perpetuate these advantages. Now, therefore, while Henry yet lived was the time to stimulate the natural cruelty and suspicion of the monarch, and secure to Hertford and the Protestant interest the removal of these dangerous and formidable rivals. They were aided by parties from whom no such help could have been expected. The Duchess of Norfolk, a passionate and revengeful woman, who had long been separated from her husband, and the Duchess of Richmond, Surrey's own sister, were brought forward as accusers. Their depositions only went to assert that Surrey was rash, and had spoken bitterly against Hertford; that the Duke of Norfolk had expressed dissatisfaction at the changes in the church (no such charge being preferred against his son); and that Surrey had persisted in quartering what seemed the royal arms on his escutcheon. A suspicion was thrown out that the earl also had a design upon the king's daughter, the Princess Mary, though the fact that Surrey's wife was in existence must have been known to all. In the mockery of a trial which ensued, the only legal charge brought against Surrey was that of his assumption of the royal arms. The indictment exists, and was published by Sir Francis Palgrave in 1842 in his *Calendar of the Baga de Secretis*, compiled from the public records. The indictment commences with a description of the royal arms before the Conquest, which description is proved to have been false and fabricated, and Surrey is then accused of having put up, painted, and joined to his own proper arms, "the said arms of the king, with the three labels silver, in order to deprive, destroy, annul, and scandalize, the title of the king to the crown of England." Surrey, it is stated, made a spirited and eloquent defence. He proved that his father had borne the same arms as himself; that their ancestor, Thomas Mowbray, had received a grant of these arms from Richard II.; that the heralds had formally decided on his right to wear them, and that he had worn them for years unchallenged even in the king's presence. Never was defence more complete or irresistible; but it was in vain. The jury pronounced him guilty, and the "flower of the English nobility" was beheaded on Tower Hill on the 21st of January 1547. Norfolk—who had meanly truckled for a pardon, and basely sought to inculpate his own son—was ordered for execution on the 28th, but the king dying the night previous, his life was spared.

The poetical works of Surrey were not printed until ten years after his death, but had been extensively circulated in manuscript. They were first published in 1557 in Tottel's *Miscellany*, a collection of poetical pieces, the earliest work of the kind in our language, and which was highly popular. Surrey attempted no great original composition. His poems consist of amatory verses, sonnets, elegies, and epitaphs—transcripts of his own feelings and fancies, but carefully and brilliantly polished. He paraphrased the first five chapters of the Book of *Ecclesiastes*, and translated the Second and Fourth Books of the *Æneid*. The latter was his most elaborate performance, and being in blank verse, is remarkable as a first attempt in a new and difficult style. The versification is regular, but wants flexibility and variety of pause, which our blank verse can scarcely be said to have attained before Shakspeare. The shorter poems of Surrey show a great advance in taste and in poetical diction. Between Chaucer and Surrey there is a long and dreary waste, in which only the name of Hawes is worthy of mention; but English poetry received an impulse and refinement from Surrey which was carried forward by a succession of elegant versifiers till it attained the glory of the Elizabethan period. The fulness, breadth, humour, and tenderness of Chaucer were never reached by his noble successor. The Italian poets were Surrey's models. But when we reflect that this gallant and unfortunate nobleman was cut off at the age of thirty, and that his life was chiefly spent at the court, or in public business—in scenes of pomp, love, war, and danger—we shall be disposed rather to wonder at the extent of his attainments as a scholar and poet, than to remark that he has left but few and slight memorials of his fine intellect and cultivated genius. (R. C—S.)

HOWARD, *John*. John Howard, the philanthropist, belongs to the rare order of men who have won from the world special titles of distinction. Many persons have earned the title of Great, from Macedonia's madman to the Swede; but mankind has endowed only one man with the appellative Just. In Howard's case the complimentary addition of the Philanthropist is not a mere figure of speech.

Howard was born at Enfield (*not* at Hackney, as the monument in St Paul's asserts), where his father, a retired London merchant, had a country house. He was born on the 2d of September 1726. His father was wealthy, and was elected to serve as sheriff; but the Test-Act being then in force, he paid the fine usually paid by Dissenters to escape that honour, a policy which his son afterwards, happily for the world, refused to follow. Howard was a sickly child, and country air was found necessary to his health. He was removed to Cardington, a village in Bedfordshire, near to Woburn, where his father had a small estate. The facts of his early life are few, and are soon told. He grew in years and strength, a quiet, simple, original boy; not bright, not vigorous, not ambitious. From his two schoolmasters, the Rev. John Horsley (author of a *Latin Grammar* and translator of a version of the *New Testament*), and Mr John Eames, F.R.S., he learned but little Latin and less Greek; yet even in his early years he acquired some knowledge of living languages, and a fair acquaintance with natural science, geography, and medicine. At sixteen he was apprenticed to a grocer in the city, paying L.700 as a premium. But his father now died, and he was his own master. He therefore bought off his apprenticeship, travelled into France and Italy, bought pictures, visited famous churches and cities, and, after an absence almost of two years' duration, during which he perfected himself in French, so as to speak the language like a native, he returned to England. Here he lodged at Stoke Newington, studied medicine and meteorology, put himself on a diet of bread and tea, fell seriously ill, and married his nurse, an old woman, who was also a confirmed invalid. He was twenty-five, she about fifty-three. He married her because he believed that she had saved his life, and that no other return for her motherly kindness was sufficient.

She lived three years as his wife, when her malady wore her out, and she was buried in the churchyard of St Mary's, Whitechapel. A plain tombstone marks the spot. At her death Howard broke up his house. The earthquake at Lisbon had just occurred; that earthquake, the effect of which on the minds of men Göethe has so powerfully described in his *Wahrheit und Dichtung*. The philanthropic impulse was stirred in Howard; he believed that he could help to alleviate the calamity, and he took a berth in the "Hanover." But the Seven Years' War was then raging. French, Austrian, and Prussian armies were fighting in various parts of Europe, and English and French cruisers swept the seas in every direction. Providence threw the "Hanover" in the way of a French privateer; she and her passengers were carried into Brest. The crew and passengers were treated with extreme cruelty, were hurried from place to place, starved, and cast into loathsome dungeons. Howard's heart almost broke with indignation at the treatment suffered by his gallant and unhappy countrymen. "I had evidence," he says, "of their being treated with such barbarity that many hundreds had perished, and that thirty-six were buried in a hole in Dinan in one day." When he obtained his release on parole he went to the government, described in powerful language the scenes he had witnessed, and compelled the Commissioners of Sick and Wounded Seamen to take measures for securing an exchange of prisoners. A naval officer replaced himself; and in a few days he had the satisfaction to hear of the release of his fellow captives in Britanny.

Howard still retreated from public life. His scientific studies were continued, and on May 13, 1756, he was elected a Fellow of the Royal Society, to the *Transactions* of which he contributed three papers. Two years later he married again. "My second wife was Henrietta Leeds, whom a good God gave me the 2d of May." Such are his own words. They lived together in the seclusion of a country house for nine years, when their only child, a son, was born, and the mother died in the exhaustion of nature. Howard's public career began after her death. During her life his energies were chiefly confined to the village of Cardington, in which he commenced a reform, then new and startling, but which has, since his age, and greatly through his example, received a happy development. He was the first builder of model cottages.

When Howard went to reside at Cardington that village was about as filthy, wretched, and unwholesome as any spot in England. The neighbouring gentry followed the hounds, and exacted their rents. The poor were idle, dirty, immoral; the men passed their days in the ale-house, and their nights in the preserves; the women were ill-used, the children ignorant and neglected. Howard's property was small in the district compared with that of his neighbours, and before he began his plan he wisely added to his estate by two purchases, at once to increase his influence in the place and to obtain a larger field for operations. He then built a school for boys and a school for girls, procured good teachers, and invited the villagers (not merely his own tenants) to send their children, his only conditions being regularity, cleanliness, and attendance at some place of worship on the Sunday. At the same time he pulled down the wretched hovels in which his poorer tenants lived—hovels of a single room in which father, mother, and grown-up children had to eat and sleep—and erected larger and more commodious cottages to replace them. With the sure instinct of a reformer he saw that such hovels were not, never could be, happy homes—residences in which men with any sense of shame, any feeling of self-respect, could live contentedly while the ale-house offered its cheerful lights and jovial company as a change. He therefore undertook to remove them. His model cottages were occupied as fast as they were raised. They cost more money, yet he did not raise the rent; for, in spite of his commercial training, he had scruples about putting out money at interest, and looked upon wealth as a sacred and moral deposit placed in his hands for the benefit of mankind, not for his own private use and pleasure. In a few years some of his rich friends and neighbours, especially Samuel Whitbread (the famous brewer, and father of the celebrated politician Whitbread), seeing the success of his scheme, lent a hand in the good work. The schools flourished; the children grew clean and rosy; poaching became rare; the chapels and churches were filled; little patches of garden rose at the cottage doors; ale-houses lost some of their strong attractions; and Cardington began to strike the stranger's eye as a pretty, clean, and prosperous village.

After his second wife's death Howard busied himself with his books, his schools, and cottages. He travelled into Holland. He went to France, to Switzerland, to Italy; but he found no rest for the sole of his foot. He returned as far as Holland (his favourite country, next to his own), and went back thence to Rome and Naples. He admired the Apollo and the Gladiator, and he felt the usual raptures before the paintings of Titian, Guido, and Raphael. He saw the Pope and the Pretender; the first, "a worthy good man;" the second, "a mere sot, very stupid, dull, and bending double." He went up the mountain to Vesuvius, and down the lagune to Venice. He came home through Munich, Augsburg, and the Rhine—came home to find himself unexpectedly named sheriff of Bedford, and to begin his public career. This was in 1773. He accepted the office of sheriff, though a Dissenter, resolved not to take the usual sacraments, but to brave a bad law, and, if prosecuted, defend himself in the courts. No one prosecuted him. When the assizes opened he sat in the court, and when the trials of the day were over he descended into the jail to see in what state the prisoners were. It was the prison in which Bunyan had been thrown, and in which he wrote his immortal *Pilgrim's Progress*. Howard found it, like all the jails of the time, dirty and close; without decent accommodation for the women, and with scarcely any practical separation of the two sexes. The air was bad, the food worse, the water intolerable. The fees were high, and rigorously exacted; the jailer and his subordinates living on the wretched wages they could wring from the misery of the poor prisoners. What most of all astonished his humane heart, and violated his sense of right, was the fact that some of the accused who had been freed by judge and jury, and who had left the court without a stain, were kept in the horrid jail (for longer or shorter periods, according to their circumstances, but in some cases for *years*) until they paid the fees of jail delivery. Howard instantly brought this monstrous form of wrong before the county magistrates, and proposed that an order should be issued for the discharge of these innocent sufferers, and that a rule should be adopted in future for the instant liberation in open court of all such persons as were found not guilty. The magistrates were startled at such bold reforms; the jailer protested against the loss of his fees, which were his income, his means of life, as he had no salary from the county. The clerk of assize put in a similar protest. Howard proposed to redeem these fees by paying regular salaries to these servants of the public; but the magistrates knew of no precedent for such a course, and without a precedent they could not act. Howard undertook to find it, if such existed in any neighbouring county. He went to Cambridge, to Huntingdon, to Northampton, to Leicester, and to Nottingham, and this journey gradually extended to every town in England where there was then a prison. The object of his search eluded inquiry. He could find no precedent for charging the county with the wages of its servants; but he discovered so many abuses in the management of prisons which imagination had never conceived, and so many sufferings of which the general public knew nothing, and of which the law took no account, that he determined to devote to the examination of these wrongs, and the reform of these abuses, whatever time and money might be needful. The task cost him a fortune, and the remaining years of his life.

The inquiry now attracted public attention. At the close of his first rapid survey of our prisons, the House of Commons resolved itself into a committee, and heard his report at the bar of the House. Popham, member for Taunton, had already forced the unwilling legislature to discuss the propriety of paying fixed salaries out of the county rates; but the House had dropped the bill. Howard's revelations completed Popham's arguments. Nearly fifty years before that time the House had appointed a committee to inquire into the state of Newgate, the Marshalsea, and other London jails, when abuses came to light which caused the House to order the arrest of several governors of jails, who were tried for high misdemeanours (*Reports of the Committee Appointed to Inquire into the State of the Gaols*, 1729). But the public, as well as the parliament, shrank from the investigation of scenes so horrid, so that after an explosion of virtue on the part of Mr Oglethorpe, magnificently rewarded by a couplet in Pope, the subject was allowed to die out of recollection until the researches of Howard and the zeal of Popham raised it in a more favourable age. When the House resumed, Sir Thomas Clavering, at the instance of the committee, moved "that John Howard, Esq., be called to the bar, and that Mr Speaker do acquaint him that the House are very sensible of the humanity and zeal which have led him to visit the several gaols of this kingdom, and to communicate to the House the interesting observations which he has made upon that subject." This vote put the seal of public sanction on his inquiries, so that his subsequent investigations had a sort of semi-official character, of vast use to him in dealing with morose jailers and impracticable magistrates of the very old school.

From St Stephen's, Howard went to the Marshalsea, afterwards to each of the London prisons, which he minutely examined. From London he passed to the north of England, whence he was recalled by the passing of two new bills, based on Popham's abandoned measure of the previous session and on his own communications to the House. The first bill provided for the liberation, free of all charges, of every prisoner against whom the grand jury failed to find a true bill, giving the jailer a sum from the county-rate in lieu of the abolished fees. The second bill required justices of the peace to see that the walls and ceilings of all prisons within their jurisdiction were scraped and whitewashed once a-year at least; that the rooms were regularly cleaned and ventilated; that infirmaries were provided for the sick, and proper care taken to get them medical advice; that the naked should be clothed; that underground dungeons should be used as little as could be; and generally that such courses should be taken as would tend to restore and preserve the health of the prisoners. That such simple provisions should have been denied in Christian England, and in the days of Addison and Johnson, is not easy to conceive, after the changes of eighty years, brought about through the exertions of one strong man. Yet the corroborative evidence of the state of prisons leaves no room for doubt. Defoe and Fielding have both left descriptions of jail life, which, though relieved by gross humour, and animated by studies of eccentric character, are not less revolting than the plain and tragic revelations of Howard. Men were callous to sufferings which seemed inevitable to misfortune, as well as to crime. Even horrible catastrophies, when they occurred, excited no more than a passing interest. The jail distemper always raged more or less in the county town, and especially during assizes. Judges and juries were sometimes swept away by the awful pest (Baker's *Chronicle*, 353); and yet no one cared to remove the causes of the jail distemper, until the Howard-Popham bill was carried on the 2d of June 1774.

It was one thing to have the bill carried in the House of Commons; it was another to have it carried into the jails. Most of the jailers were ignorant, rapacious fellows; and some of them were women—as a rule more ignorant and rapacious than the men. The new law struck at their interests, and cordial feeling towards it was not expected from human frailty. Howard resolved to see it executed with his own eyes; he caused the provisions of the act to be printed at his private cost, in large type, and he sent a copy to every jailer and warder in the three kingdoms, so that no one could be able to plead ignorance of the law, if detected in the flagrant violation of its provisions. He then recommenced his inspections—travelled into the west of England, into Ireland and Scotland. Beyond the special cause to which he had given up his time, he took little interest in political matters, though he entertained strong opinions about the unjust aggression of the government in America, and expressed these opinions in a way to render the possibility of his appearance in the House of Commons as an independent member extremely distasteful to ministers. When, therefore, an election took place for Bedford, and Howard's friends proposed him as a candidate, all the arts of corruption were used to keep him out. He was nevertheles elected. On the return being disputed, the election committee, which was completely under the ministers' hand allowed a number of pauper votes which had been bought up and recorded in favour of the opposition candidates, though these votes had been refused before—just enough to unseat Howard by a minority of four votes. "I was made a victim by the ministry," he writes to a friend; "most surely I should not have fallen in with their severe measures relative to the Americans; and my constant declaration that not one emolument of five shillings, were I in parliament, would I ever accept of, marked me out as an object of their aversion." It was a fortunate decision, as it left him to his own peculiar work. Set free from all other occupations, instead of embodying his observations on English prisons at once in a book, he thought it better to make a tour of France, the Austrian Netherlands, Holland, and Germany, to see the most famous and infamous prisons on the continent of Europe, collect their various laws and regulations, and compare their structure, their action, and results with those of our own. In Paris he was denied access to the prisons; but in looking over the old legislation on the subject, he found a provision in an act of 1717, that any person wishing to distribute alms to the prisoners was to be admitted to the interior, and allowed to dispense his bounty with his own hand. The law had fallen into disuse, and was unknown to the keepers. Howard appealed to higher authority, and the validity of the old act was allowed. At some expense in charities, he inspected the Bicetre, the Force l'Evêque, and other places of confinement: but neither money nor interest could open the Bastile to his inspection. He once stepped inside its gates at some personal risk. A suppressed pamphlet, describing the interior, written by a man who had suffered confinement, he obtained after much trouble, brought back to England, translated, and gave it to the world in his own book, an offence which the French government never forgot and never forgave. At Ghent he examined with deep interest the Great Reformatory Prison, a model for all Europe, combining the elements of industry and privation, which are still esteemed the most efficacious means of reformation. At Amsterdam he was struck with the slight amount of crime in the Dutch cities, contrasting as it did so fearfully with the crime in his own country. For 100 years then past the executions in Amsterdam, a city of 250,000 inhabitants, had averaged no more than one in twelve months. London, with its 750,000 inhabitants, had an average of 29½ executions a-year, or, reckoning population against population, ten in London to one in Amsterdam (Janssen's *Tables*, 1772). In the United Provinces he found that the industrial system penetrated the jail. In England we only thought of punishing offences; there they sought to reclaim offenders for society. We put them into dungeons; they put them into workshops. They made the criminals *work* their way back to freedom. Their professed maxim was—"Make them diligent and they will be honest." Howard did not forget the hint. In Germany he found little that was useful, much that was disgusting. In Hanover and Osnaburgh, under English rule, he found traces of torture. Hamburgh was less revolting, as were generally the commercial cities. He returned to England with his papers, plans, and rules, a voluminous and precious collection, as original in character as it was humane in purpose; but before putting his materials in the printer's hands, he undertook another comprehensive tour through England, revising his former observations, adding new notes to the record, relieving distress, liberating poor debtors, superintending the operation of the new jail act; and when these enormous labours were completed after seven months of daily toil, the gains from this careful revision seemed so important to his mind, that he resolved to give his continental experiences the benefit of a similar collation, and also extend his researches into some countries, the prisons of which he had not yet seen. He set out for Lyons, crossed to Geneva (where he was rejoiced as a republican to find only five persons in confinement), whence he passed on to Berne, through cantons in which there was not a single prisoner; he went on to Soleure and Basle, delighted with the cleanliness, the Christian discipline, and considerate government of all the jails of Switzerland, and struck into Germany and Holland, visiting or revisiting the most celebrated prisons. He returned to London, and published his remarkable book, *The State of Prisons in England and Wales*, in 1777. In collecting his materials he had spent between three and four years, travelling not less than 13,418 miles. He contrasted in its pages the condition of our own and of foreign prisons, very much to the disadvantage of the former. "The reader," he says, "will scarcely feel from my narrative the same emotion of shame and regret as the comparison excited in me on beholding the difference with my own eyes; but from the account I have given him of foreign prisons he may judge whether a design of reforming our own be merely visionary—whether idleness, debauchery, disease, and famine be the necessary attendants of a prison, or only connected with it in our ideas, for want of a more perfect knowledge and more enlarged views."

The book made a sensation. One of the first results was to give a new impulse to the question—What to do with our convicts? America refused to take them any longer; Australia had not yet offered itself as a receptacle for the rascality of England. Government was at its wit's end; and crotchety people were urging every kind of scheme on its attention. A hulk (the "Justitia") had been already stationed in the river, off the arsenal at Woolwich, for the reception of convicts, who were treated as in the worst prisons of the old school, so that every kind of disorder existed in the ship. Howard hoped for no success without a change of system; but his continental experience convinced him that home discipline was better for the criminal than deportation to a new country; and, after much consideration by ministers, his idea of trying *the discipline of hard work* was adopted, and Sir William Blackstone and Mr Eden were requested to make out the draft of a bill for the creation of a fitting establishment. A new prison was needed for the new plans; no jail in the country could answer for a trial; and Howard volunteered to go abroad and collect plans and other precise information.

He went to Amsterdam, and carefully examined the spin-houses and rasp-houses for which that city was famous. He passed into Prussia, Saxony, Bohemia, and Austria, through the lines of the German armies commanded by the Great Frederick and the Emperor Joseph II. His fame had gone before him, and he was received with the greatest distinction in Berlin and Vienna. He spent a morning with the Prince of Prussia, and dined with Maria Theresa. From Vienna he went to Italy, which he traversed from Venice to Naples, inspecting prisons, hospitals, and workhouses, and carefully hoarding up the peculiar merit or fault of each, for the use of Sir William Blackstone and his colleague. On his return from Naples towards Leghorn, he encountered a violent storm, which raged for three days with great fury. The little shallop, unmanageable, was driven on the Tuscan coast, but the inhabitants, fearful of plague, refused to allow the passengers to land. Driven back again upon the storm, they were carried by its force to the African shore, to be again driven off by the same fears. They had started from Civita Vecchia while the pest was raging there, and their foul bill of health alarmed Christian and Mohammedan alike. Howard suffered fearfully in health by this trial; and, after his prison labours were accomplished, and his health fully restored, he turned to the new and fearful enemy, and finally lost his life in an attempt to discover the cause and the remedy for plague.

During this rapid continental tour he travelled 4600 miles. While in France his attention was again drawn to his old subject—the infamous neglect and unchristian treatment of prisoners of war. He was told that these prisoners were treated worse in England than elsewhere; that their loyalty was tampered with; and that they were systematically ill-used in order to compel them to forswear their allegiance, and enter the English service. Burning with indignation, he went to the Commissioners of Sick and Wounded Seamen, who expressed their astonishment at such assertions; and, on his saying that he meant to look into this affair for himself, they offered to assist his inquiries. Our prisoners of war had reason to be grateful for his interference.

The information obtained during his foreign tour was placed at the service of the House of Commons. A bill was introduced and passed for building two penitentiary houses in Middlesex, Surrey, Kent, or Essex (as might be determined afterwards), in which to try the experiment of a discipline of work. Howard was appointed first supervisor of this Act; Mr Whatley, of the Foundling Hospital, second; and Howard was allowed to name the third, Dr Fothergill (stat. 19 Geo. III., cap. 74). The scheme, however, under official restraints, proceeded slowly; Howard felt that his life was being wasted in small quarrels and unimportant discussions with Mr Whatley as to the sites of the proposed penitentiaries; and both Sir William Blackstone and Dr Fothergill dying while Mr Whatley was disputing, he wrote to Lord Bathurst, president of the council, begging the king's permission to resign his office. An impulse, however, had been given. Howard's ideas were adopted in many places. In all the new prisons erected from that time provision was made for setting the criminals to work. He turned his face to the continent, with a view to collect whatever might be useful to his countrymen in those lands which he had not yet visited; and began a new and longer journey, which gradually embraced the whole circle of Europe, his route lying through Holland, Schleswig, Denmark, Norway, Sweden, Russia, Poland; thence back to London, and so on to Portugal, Spain, France, and the Austrian Netherlands. This journey was full of curious and romantic incidents. At its completion Howard gave his collections to the public in a new edition of his *State of Prisons*, with appendices.

Being now free from serious responsibility as regards the subject of prisons, and being determined not to enter parliament (as he was again requested to do), he reverted to the terrible idea of the Plague. English commerce with the Levant was rapidly extending, and serious thoughts were entertained in official circles of establishing a regular quarantine (as at Marseilles and Venice) against all vessels arriving from the East. But nothing was known in England about lazarettos and quarantine establishments; and the plague itself (from vague historical recollections of the London pests of 1603 and 1665, when the disease swept away each time one-fifth of the population) (Petty's *Political Arithmetic*, 1686) was regarded with a terror more superstitious than rational. Government desired information; Howard offered to procure it, and equipped himself for the journey. He proposed to begin his studies at Marseilles with the newest of the lazarettos; afterwards to visit those of Venice and Leghorn; and, having gained all preliminary information in these cities, to proceed to Smyrna and Constantinople, the proper homes of the plague, and there study its symptoms and modes of treatment. The French government, however, mindful of the Bastile pamphlet, refused him a passport; so that, instead of gaining facilities for inspecting the lazaretto at Marseilles, he was peremptorily forbidden to set foot in the territory of France. Lord Carmarthen, our ambassador in Paris, tried in vain to remove the bann; but, as Howard considered that his journey would lose much of its interest, and its chief use as regarded his own country, if he missed the fine lazaretto at Marseilles, he defied the threats held out, put himself into a good disguise, and entered France in the usual way among travellers in the diligence. A police agent attended him to Paris, for the French ambassador at the Hague had received intelligence from M. Le Noir, director of police in Paris, to keep watch over his movements; and it was by a miracle of rapid and courageous action that he escaped a dungeon in the Bastile. Sometimes as a French physician, sometimes as an exquisite of the Faubourg St Germain, he traversed France as far as Marseilles, obtained admission to the lazaretto, and shelter in the house of a Huguenot pastor, although the police were on the look-out for him, with a description of his person in their hands. His courage, his disguise, and his perfect manners, threw them off their guard; yet the risks he ran were very serious, and he breathed more freely when he had crossed the frontier. "I have now taken a final leave of France," he wrote to a friend from Leghorn; "I am sensible that I ran a great risk, but I accomplished my object. Happy was I to arrive at Nice, out of the country of a deceitful, jealous, and ungenerous people." He went to Florence, Rome (where he had an interview with Pope Pius), and Naples; and thence to Smyrna, where his skill as a doctor opened all the prisons and hospitals to his inspection. He remained at Smyrna, performing a few simple cures which rumour vastly magnified, until a fatal form of the plague broke out, and he had first-rate opportunities of studying it. He went on to Constantinople, whither the fame of his cures had gone before, and as soon as he arrived he was called in by a great pasha to treat the case of his daughter, who had been given over, it was said, by all the Italian doctors. She recovered; and of course Howard's fame rose with his wonderful work. He confined his visits, however, to the pest-houses, the prisons, and hospitals; he said he was only a physician to the poor. Our ambassador, Sir Robert Ainslie, aware of his patriotic and humane object, offered him a home at the embassy. This he declined, as being unwilling to expose another to the fearful risk of contagion, and took up his residence in the house of a physician, to whom he could communicate the course of his daily experience, as well to receive sound advice as to prepare his host for prompt action in case he brought the plague home. But he bore a charmed life. The smitten fell dead at his feet. He went into infected caravansaries and into pest-houses whither physician, guide, and dragoman, all refused to follow him. From these fearful visits he returned with a scorching pain across the temples, though an hour of fresh air and vigorous exercise served to carry it away. At length his researches were complete. With a trunk full of papers—plans of lazarettos, opinions of celebrated physicians living in the Levant, and copies of regulations and instructions—he prepared to return, and wrote to inform his friends of his intention to cross overland to Vienna. But while his preparations for departure were in progress, the idea flashed across his mind that all his acquired knowledge, various as it was, had been obtained from others—was second-hand, not original; that he had seen but not suffered the discipline of a European lazaretto; and that, possibly, something of material import to the practical working of the scheme (the want of which would be felt as soon as the system was commenced, if it ever were commenced, in England) had escaped his notice. The fear was enough. Altering his plan, he resolved to return; to find a foul ship, make the voyage in her to Venice, and there undergo the usual confinement of the suspected in the famous lazaretto of that city. Such a plan was full of peril. A late ambassador, Mr Murray, had died of the plague in that very lazaretto; but nothing would deter him from his purpose, and he departed. Plague broke out in the ship, and a strong man died in a few hours; yet he went on to Smyrna, deliberately sought out a foul vessel, took his berth, and started for Venice. On the way they were attacked by pirates, when Howard astonished the Venetian sailors by his courage and by a lesson which he gave them in the noble art of gunnery. They acknowledged that the English physician had saved them from the slave market of Tunis or Tripoli. On the sixtieth day of the voyage they arrived in Venice, and were all transferred to the lazaretto, where Howard's health suffered severely from the confinement, though he was supported with the thought that he was gaining precious experience. His minute account of the discipline of this famous lazaretto is most interesting (*Lazarettos of Europe*, pp. 10–22).

Howard came out of his confinement reduced to a skeleton and flushed with fever. However anxious to get home (for a dreadful domestic calamity had occurred; his only child, now a young man, had lost his reason, and was under the charge of a keeper), he was too weak to travel for some days. He went to Trieste and Vienna, where he held a long and exceedingly curious interview with the Emperor Joseph II., himself a reformer, or rather an innovator, during which the English gentleman told the German ruler some very unusual truths. He reached England in February 1787, having been absent on his extraordinary mission sixteen months.

As soon as his domestic concerns were put into such order as they admitted, and his great work on the *Lazarettos of Europe* was published, Howard begun a fresh and final review of the prisons of the three kingdoms. He visited all with care, and presented a bible to each of those in the county towns. Vast improvements had already taken place in the management and discipline of the prisons, in the food, clothing, work, and Christian teaching of the prisoners. Foremost among the magistrates who adopted the new system were those of Manchester. They built on the banks of the Irwell a large prison, with an express view to carrying Howard's ideas into effect; and on the foundation-stone of the edifice they set this inscription—"That their may remain to posterity a monument of the affection and gratitude of this country to that most excellent person, who has so fully proved the wisdom and humanity of the separate and solitary confinement of offenders, this prison is inscribed with the name of JOHN HOWARD." This final tour of the English jails occupied him for eighteen months; and the results of his inspection were recorded in a new edition of his *State of Prisons*.

While in the Levant he had enjoyed many opportunities of hearing the opinions of merchants and consular agents on the prospects of our trade with the East. It was said that were it not for fear of the plague that trade might be at once doubled. As we were without quarantine establishments, the people were afraid of any ship from infected districts; the consequence of which fear was, that the Dutch ran away with the traffic, without taking sufficient care about the plague. So we lost the profits without escaping the risks, as the Dutch ships might as easily introduce the pest at second hand as our own at first. This idea settled in Howard's mind, and helped to shape towards a more practical end those purposes which he pursued from purer and more romantic motives. In the postscript to his new book on *Lazarettos*, he told the public of his intention to follow up the new inquiries. "To my country," he said in a few noble and simple words, the last he addressed to it in print, "I commit the result of my past labours. It is my intention again to quit it for the purpose of revisiting Russia, Turkey, and some other countries, and extending my tour into the East. I am not insensible of the dangers that must attend such a journey. Should it please God to cut off my life in the prosecution of this design, let not my conduct be imputed to rashness or enthusiasm, but to a serious conviction that I am pursuing the path of duty." These words were prophetic.

From London he went to Riga, thence to St Petersburg and Moscow, from which place he proposed to travel to Warsaw, and through Vienna to Constantinople. But the war overruled his plans. Russia and Turkey were struggling fiercely on the Dnieper and the Pruth. Bender had just fallen, and the Muscovites were hurrying their forces to the south. Sad as had been his experiences, Howard had seen nothing to compare in atrocity with the reckless waste of life in Russia in time of war. The roads were almost choked with dead bodies. Raw recruits, most of them too young to bear privation, were hurled by forced marches, and at every sacrifice, towards the theatre of war. They dropped, and were left to die. Hunger, hardship, fever, thinned the ranks as they staggered on towards the Black Sea. Howard had no sympathy with military glory; and the sickening sights which he witnessed on the roads from Moscow to Kherson disgusted him with the hypocrisy of Russia's boast of having become a civilized power. Even the great question of the plague was laid aside for a while, in presence of all these horrors to be brought to light, all these miseries to be assuaged. In his portmanteau he had carried out, for the use of his expected plague patients, a quantity of James's powders, a medicine believed to possess all save miraculous powers; and he thought he should do wisely in placing these powders at the service of the poor Russian serfs who were falling in crowds around him, the victims of an infernal military system. So he went down to the coasts of the Black Sea, visited the hospitals of Crementschouk, Otschakow, St Nicholas, Kherson, and other places. His letters and his notes in his journals are heart-rending. "They are dreadfully neglected. A heart of stone would almost bleed! The abuses of office are glaring, and I want not courage to tell them so." Russian officials, with the cunning of an Asiatic race, so soon as they saw that Howard would expose their cruelties, and disabuse the western public of its false estimate of Russian civilization, an estimate drawn from the splendid misrepresentations of Voltaire and those French theorists who were willing to depose Providence in favour of the Czars—began to throw dust in his eyes. They prepared the hospitals for his reception, removed the more unsightly objects, pretended that he had inspected all where he had only seen a few prepared wards; but his experience defeated these attempts at imposition, and his conductor gained nothing save the dishonour attaching to a mean trick. Whoever wishes to see the military system of Russia in its true character, as conducted in the villages and cities of the Muscovite empire, must study the memorials of Howard's last visit to Russia.

He died in the midst of his labours. He caught the camp fever at Kherson, from a young lady whom he attended as a physician, and died in that city on the morning of January 20, 1790, and was buried on the road to St Nicholas. (H. D—N.)

HOWDEN, a market-town of England, East Riding of Yorkshire, 20 miles S.S.E. of York, and about a mile N. of the Ouse, where there is a ferry and a small harbour for boats. The church, formerly collegiate, is a spacious cruciform edifice, chiefly in the decorated English style, 255 feet long by 66 feet wide, with an elegant square embattled tower 135 feet high. The chapter-house is an octagonal building with 30 stalls. Near the town, and now used as a farm-house, are the remains of an ancient palace of the bishops of Durham. Market-day, Saturday. One of the greatest horse fairs in England is held here annually on 25th Sept., and 6 following days; and here most of the horses for the army are obtained. Pop. (1851) 2235.

HOWE, John, in some respects the greatest of the Puritan divines, was born at Loughborough, in Leicestershire, May 17, 1630. His father had been presented to the living of that parish by Archbishop Laud, but refusing to comply with the tyrannical edicts of that prelate, had been compelled to fly for safety to Ireland, along with his son, at that time hardly five years old. When the Irish Rebellion of 1641 broke out, the exiles returned to England. Fixing his abode in Lancashire, the elder Howe conducted in person the studies of his son, who in his seventeenth year entered Christ's College, Cambridge, as a sizar, and in the following year graduated as a bachelor of arts. During his residence at this university, he had the good fortune to make the acquaintance of the famous Cudworth, and the ingenious, though eccentric, Dr Henry More; from intercourse with whom, as Calamy suggests, his mind received that "Platonic tinge" which distinguishes his writings. Immediately after graduation, Howe removed to Oxford, where he took the same degree in the following year. Anthony Wood has traced his various remaining steps at Magdalen College, where he was first appointed a "demy" by the parliamentary visitors, soon afterwards raised to fellowship, and in 1652, when he was only twenty-two years of age, "proceeded" master of arts. On leaving Oxford, he returned to his father's retreat in Lancashire, and soon after received ordination at Winwick from the hands of Mr Herle, the clergyman, and the ministers of the neighbouring chapelries. In a little time "an unexpected conduct of divine Providence" bore him to Great Torrington, in Devonshire, where he was engaged as pastor. It was here that he preached those discourses which at a later period took shape in his treatises on *The Blessedness of the Righteous*, and on *Delighting in God*. It was here also that he married the daughter of his "inner friend," Mr George Hughes, a minister of great name and influence at that time in Plymouth.

In the beginning of 1657, a journey to London accidentally brought Howe under the notice of Cromwell, who, struck by his appearance and preaching, made him his domestic chaplain. It was in vain that Howe pleaded the interests of his people at Great Torrington; Cromwell would take no refusal; and the result was that Howe was soon installed in Whitehall.

His conduct in this high position was such as to extort the praises of even the warmest enemies of his party. Without overlooking the due claims of the Puritans, he omitted no opportunity of advancing pious and learned men of other denominations. Ward, the future bishop of Exeter, and Thomas Fuller, were in the number of those who profited by Howe's kindness, and were not ashamed subsequently to express their gratitude for it. Cromwell's charities were for his age munificent, and Howe was his frequent adviser and almoner; but he dispensed so liberally to others, and asked so little for himself, that the Protector could not help remarking upon his self-denial: "You have obtained many favours for others," said he, "I wonder when the time is to come that you are to ask anything for yourself or your family." Howe, in common with Dr Owen, appears to have believed in Cromwell's religious sincerity, but his conscience would not allow him to be silent when he saw the Protector countenancing doctrines that seemed to savour of fanaticism. It was at one period a pet idea at Whitehall that "the particular thing asked by Christians in prayer will be granted, whatever it be." Howe, convinced of its dangerous tendency, opposed it from the pulpit. Cromwell was observed to knit his brows as his unflinching censor proceeded; and his subsequent bearing towards him was colder. At the suggestion of Baxter, he embodied, in "a number of small volumes," his notes on the leading personages and events that illustrated the Protectorate. These volumes, which must of necessity have thrown much light on many of the dark passages of that period, were unfortunately consigned to the flames by Howe's son, in compliance with strict injunctions issued by himself shortly before his death.

After the Restoration, Howe returned to Great Torrington. Like all who had played a conspicuous part in the Commonwealth, he soon found himself an object of suspicion and hatred to the new government. Spies were set upon his track; his words were watched by base informers; he was even accused on one occasion of uttering seditious and treasonable language in his sermons; and tried before the quarter-sessions. His accusers, however, could prove nothing against him, and he was honourably acquitted. When the "Act of Uniformity" silenced more than two thousand of the best ministers in England, Howe was driven from his parish, and for several years led a wandering and uncertain life, preaching in secret, as occasion offered, to handfuls of faithful hearers. More than once his liberty was in imminent jeopardy, and it is understood that for some months in 1665 he was confined in the Isle of St Nicholas, in Plymouth Sound. On his liberation, he proceeded to meet the demands of pressing want by publishing his *Blessedness of the Righteous*, which, among other advantages, procured him an invitation from Lord Massarene of Antrim Castle, in Ireland, to become his domestic chaplain. Ecclesiastical espionage was not so rigorous in the sister island. And Howe, accepting the invitation, returned in 1671 to that Ireland which had already afforded him an asylum when a child.

During the five years which he spent in this peaceful and safe retreat, he frequently preached in public, with the approval of the bishop of the diocese, and also found time to produce the most eloquent of his shorter treatises, *The Vanity of Man as Mortal*, and his *Delighting in God;* the latter of which he dedicated to his Torrington parishioners. Here, too, he planned his largest and greatest work, *A Good Man the Living Temple of God*, which, in its metaphysical speculations, anticipated the profoundest reasonings of Samuel Clarke, and in sustained sublimity of thought is not surpassed in English theology.

In 1676 Howe returned to England, and became pastor of a Nonconformist congregation in Silver Street, London. His fame had by this time increased so much that the leading men of the national church, such as Stillingfleet, Tillotson, Kidder, and others, gladly courted his friendship. In the society of these men, and in miscellaneous literary work, Howe spent the troubled years that followed his settlement in London in tolerable peace and safety. The first part of his *Living Temple* appeared in 1676; the second part was delayed till 1702. In 1677 appeared his tractate *On the Reconcileableness of God's Prescience of the Sins of Men, with the wisdom and sincerity of His counsels, exhortations, and whatsoever means He uses to prevent them.* This latter work was attacked from various quarters. In the number of those who stepped forward in its defence was Andrew Marvel. His work *On Thoughtfulness for the Morrow* followed in 1681; those on *Self-Dedication* and *Union among Protestants*, in 1682. The execution in 1683 of that most virtuous patriot of his times, Lord William Russel, drew forth from Howe a letter of condolence to his lordship's widow, which James Montgomery has pronounced to be "one of the noblest and most pathetic pieces of epistolary composition in the language." In 1684 he gave to the world the most pathetic of his works, *The Redeemer's Tears Wept over Lost Souls.* Meanwhile, anxiety and over-work had undermined his health; and in 1685 he gladly accepted the invitation of Philip Lord Wharton to travel with him on the Continent. It affords a striking picture of the times that his departure from London needed to be managed with so much secrecy and suddenness that he first announced it to his people by a letter written from the other side of the Channel.

His journey extended over the greater part of a year, during which he visited the most celebrated cities on the Continent. At the end of that period, as matters still seemed hopeless in England, he determined to settle for a time at Utrecht. He secured an honourable maintenance by keeping a boarding school, officiating in the English chapel on Sundays, and by reading privately with English students at the university. In the number of his private friends was Burnet, the future bishop of Salisbury, by whose influence he obtained access several times to William Prince of Orange. The future king of England, as Calamy assures us, "conversed with Howe with the greatest freedom." Meanwhile, as Howe was looking wistfully for tidings from England, the news reached him of James II.'s "Declaration for Liberty of Conscience," and Howe took advantage of it to return to London, where his presence was keenly desired by his congregation. Another year brought William of Orange to the British throne, and placed liberty of worship on a stable basis, which was rendered still more secure by the passing of the Act of Toleration. Howe fitly headed the procession of Nonconformist divines who went to congratulate William on his accession to the English throne; nor did the monarch, amid his new cares and dignities, forget the confidential intercourse of Utrecht, but sent for Howe repeatedly to Kensington, and showed especial delight in asking questions about his "old master, Cromwell." To quell those troubles and divisions that broke out among the Nonconformists on disputed points of doctrine and church government, Howe published, in 1693, his three discourses, so full of Christian wisdom and charity, *On the Carnality of Religious Contention*, which, however able, as they confessedly were, remained for many years unheeded.

Some of the most acute writers of the age, such as Wallis, Sherlock, South, and Cudworth, had already given to the world dissertations on the subject of the Trinity; and in 1694 and 1695 Howe published various treatises on the same theme, the principal of which was entitled, *A Calm and Solemn Inquiry concerning the Possibility of a Trinity in the Godhead.* His aim in these essays is not so much to state the Scripture testimony on this doctrine, as to show what incompetent judges men must be of the nature of the Divine simplicity, and how presumptuous all *a priori* speculations must be on such a matter as the mode of the Divine existence. It had been Howe's aim throughout his long life to combine with the assertion of his individual convictions, a recognition of the essential unity and brotherhood of all true Christians; or, as Bacon expresses it, to see "charity moving on the poles of truth." In vindication of his right of private judgment, he had separated from the establishment; in expression of his charity, he had continued to practise occasional communion within its pale. The propriety of this conduct, in which Howe had many followers, was keenly agitated in the ecclesiastical world towards the beginning of the last century, and Howe led the van in defence of "occasional communion." Few may concur with him in every practical application which he made of his principles, but the principles themselves, which this controversy was the occasion of elucidating, are now generally admitted, and have been reproduced in some of the most splendid treatises of Robert Hall.

In his seventieth year, Howe, warned of his own approaching end by the death of his great contemporaries, Owen, Baxter, Bates, and Mead, produced one of his richest treatises, *The Redeemer's Dominion over the Invisible World.* As if to leave no important department of inspired theology untouched, he gave forth in 1701, *Discourses on Man's Enmity against God and Reconciliation to Him.* In the spring of 1705 appeared his last publication, entitled, *On Patience in Expectation of Future Blessedness.* The symptoms of failing strength now became apparent in "frequent languishments," aggravated by more than one painful malady. Multitudes now came to visit the death-bed of the great Puritan, and retired from the solemn interview

Howe, John.

feeling that there was something as uncommon in his death as in his life, and that his converse was "like that of an inhabitant returned from another world." Among the number was Richard Cromwell, now an old man. "There was a great deal of serious discourse between them," says Calamy, "tears were freely shed on both sides, and the parting was very solemn and affecting." Howe did not long survive this interview. He died April 2, 1706, in the 77th year of his age.

It was the rare achievement of this great man to pass through an age of social convulsion and tempest, and to occupy positions the most perilous for the trial of character, and to emerge from the ordeal unscathed. Baxter's impetuous temperament betrayed him at times into inconsistency. Owen was more than once too diplomatic for a divine; but even detractors, in their most bitter denunciations of the Puritans, have usually excepted Howe. That must indeed have been no common moral greatness which awed Cromwell into silence, moved Tillotson to tears, overcame the constitutional reserve of William, and "smoothed the raven-down" of the monkish Anthony-à-Wood, until he smiled and praised.

Considered intellectually, he may be affirmed to have combined many great qualities, the possession of any one of which, in an equal degree, would have been sufficient to raise him to eminence and fame. Excelled by Baxter in pulpit oratory, and by Owen in theological learning and exegetical tact, he was by far the most profound and philosophical thinker of all the Puritans, and perhaps produced a greater number of original and uncommon thoughts than any other theologian of his age. Scarcely surpassed by Edwards in logical acumen, or by Butler in ingenuity and depth, how far does he transcend both in pathos and imagination. And yet his imagination does not overlay his thoughts, as is sometimes the case with Jeremy Taylor; it is a trained faculty, the beautiful handmaid of reason, bearing it up into the sunlight "on wings of silver and feathers of yellow gold." His writings abound in sublimity, but are comparatively passionless. In this respect Baxter's style resembles the impetuous flow of the broad river, Howe's is that same river expanded into a calm lake, whose quiet depths are the mirror of innumerable stars. One characteristic effect of his writings is to tranquillize and elevate the soul. You feel yourself seated on some lofty mountain, in a serene air, and looking down upon clouds and storms far beneath your feet. As we read him, he brings up Milton's picture of contemplation to our thoughts,—

> "With even step, and musing gait,
> And looks commercing with the skies."

Yet, as a writer, Howe is not without the characteristic faults of the Puritan divines. The tendency to dilate on what should only have been touched, and to check the continuous flow of thought and style by minute and perplexing subdivisions, has seriously diminished his popularity as a writer. Often his diction is not equal to his thoughts, and we almost wish, after he has brought out and shaped the marble, that he had invited Bates or Tillotson to add the tracery; though in some of his greatest passages, such as his immortal comparison of the soul of man to a temple in ruins, the flight is nobly sustained, and his words come with all the opulence of Jeremy Taylor's finest passages, and take their place, as if guided by a magician's wand. But when all these deductions are made, John Howe must be recognised as one of the primary stars in the firmament of English divines, shining with a serene lustre peculiarly his own; and if Jeremy Taylor has been styled the Spenser, Howe may with equal justice be styled the Milton of English theology. (A. T.)

Howe, Richard.

Howe, *Richard* (*Viscount Howe*), the first naval officer of his day, was born in 1725. His father was Emanuel Scrope Howe, governor of Barbadoes, and his mother was a daughter of Baron Kielmansegge, master of the horse to George I. when elector of Hanover. Leaving Eton at the age of fourteen, he entered the navy, and joined the fleet which the English were then sending out under Anson to carry on the war against Spain in the Pacific. In this expedition he distinguished himself so much that in his twentieth year he rose to the rank of lieutenant. After some minor exploits, he signalized himself by gallantly defeating, off the Scottish coast, two French vessels of greatly superior size and strength to his own which were carrying supplies and reinforcements to the Pretender. For this exploit he was made a captain on his arrival in England. The next seven years of his life were spent in miscellaneous service in the West Indies, Africa, the Mediterranean, and the Northern Atlantic. When the Seven Years' War broke out, Howe was chiefly engaged in watching the southern and western coasts of France, and besides many minor exploits, defeated the French squadron under De Conflans, and took two of the enemies' ships. His brilliant career attracted the notice of the king (George II.) himself, who expressed the sentiment of the nation when he told Howe on his return home that his life had been an unbroken series of services to his country. Shortly before the close of the war Howe had married, and on the death of his elder brother, had inherited the title and estates of the Viscounts of Howe. On the proclamation of peace, he was made treasurer of the navy, with a seat at the Admiralty Board, and afterwards sat in parliament for Dartmouth. In 1770 he was made rear-admiral of the blue, and commander-in-chief of the Mediterranean fleet. Six years later, in the war of the American independence, he maintained his high character by the dashing success of his attack on the French fleet, which was cruising off Rhode Island under the Count d'Estaing with the view of aiding the revolted colonists against the mother country. On returning home he took command of the English fleet, which sailed to relieve Gibraltar, and in the teeth of many difficulties was completely successful. The remark made upon him some eight years before, by Lord Hawke in the House of Peers, continued to the last to hold as true as when it was first uttered, "I have tried my Lord Howe on many important occasions; he never asked me how he was to execute any service, but always went and performed it." On his arrival in England after this exploit, he was created Earl Howe, and succeeded Lord Keppel as first lord of the admiralty. When the war of the French Revolution began, Howe was chosen commander of the Channel fleet, and on June 1, 1794, gained the greatest of all his victories—that in which he defeated the French fleet off the western coast of France, dismasting ten of the enemy's ships, and taking seven, of which he brought off six in safety into Portsmouth harbour. The seventh, the Vengeur—about whose glorious resistance the French, on the lying report of Bertrand Barrère, sang so many Io Pæans—was so much shattered that she sank in the attempt to tow her away. (See Carlyle's Essay on the "Vengeur," in his *Miscellanies.*) Less brilliant, but not less useful, was the service which Lord Howe next rendered to his country,—by his suppression of the terrible mutiny of the British fleet at Portsmouth and Spithead. The means he took to recal the sailors to their duty, such as his dismissal of the obnoxious officers, &c., were a good deal canvassed at the time, but they certainly had the desired effect. Age and long service now began to make rapid inroads upon the old admiral's constitution, and he found himself compelled to retire from the service which he had graced with so many triumphs. He did not live long to enjoy the repose he had so dearly earned, dying under a violent attack of the gout, Aug. 5, 1799.

Lord Howe was the ablest British seaman of his day, and his ability and technical skill had endeared him above all his brother officers to the sailors, among whom, from the darkness of his complexion, he was familiarly known as Black Dick. He used no mean arts to gain this popularity, for he was extremely reserved in manner, and a most rigid disciplinarian. But his cool courage and presence of mind in the midst of danger, the strength and soundness of his judgment, and his strict impartiality, fully compensated the want of those graces which sometimes gain for their possessor a temporary and factitious repute. In person he was tall, strong, and well-made, and capable of enduring almost any amount of fatigue. His features, until lighted up by his smile, were harsh even to grimness.

HOWITZER, a short piece of ordnance. See GUNNERY.

HOWTH, a small town of Ireland, county of Dublin, 8 miles N.N.E. of the capital, with which it is connected by railway. It stands on a peninsula of the same name, rising 567 feet above the sea, and forming the northern boundary of Dublin Bay. An artificial harbour, formed here at an expense of above one-third of a million sterling, is now almost choked up with sand, and is accessible only to vessels of small burden. Pop. (1851) 829, chiefly engaged in fishing.

HOY. See ORKNEY ISLANDS.

HUAMANGA, a town of Peru. See GUAMANGA.

HUBELY, a town of Hindustan, in the British collectorate of Dharwar, presidency of Bombay. It is large and populous, defended by a mud rampart and ditch, and has for many years carried on an extensive trade, particularly with Goa, to which are sent sandalwood and elephants' teeth, and in return raw silk, cottons, woollens, and rice are received. There are also manufactures of raw silk and cotton, great quantities of which are sold for the dresses of the country people. It is a wealthy place, the residence of many rich bankers, who, by means of their agents, extend their commercial intercourse to Surat, Hyderabad, Seringapatam, and even to more distant places on which bills of exchange can be negotiated, and who regulate the standard of the currency in all the adjoining countries. The East India Company formerly had a factory here, which was plundered by the Mahrattas in 1673, when the company sustained a great loss. In 1685 it was taken by the Mogul troops of Aurungzebe, and soon after the death of that monarch in 1707 it was again taken by the Mahrattas, with whom it continued until 1818, when, on the overthrow of the Peishwa, it lapsed to the British, together with the rest of that prince's dominions. E. Long. 75. 13., N. Lat. 15. 20.

HUBER, FRANCOIS, author of the *Nouvelles Observations sur les Abeilles*, belonged to a family of which several members had already distinguished themselves in various walks of science, and was born at Geneva in 1750. At the age of fifteen he lost his eye-sight from the intensity with which he had applied himself to his studies; but the means he inherited from his father placed him beyond the reach of want, and enabled him to follow his bent for natural history. The devotion of his wife and of an attached secretary compensated to him in some measure the loss of his sight; and having selected the bee as the subject of his special studies, he, with their assistance, wrote on that theme the most accurate and comprehensive work that has yet appeared. (See BEE.) Huber died at Lausanne in 1831. An interesting account of his methods of study is given in Dr Kitto's *Lost Senses*.

HUDDERSFIELD, a parliamentary borough, and large manufacturing town of England, in the West Riding of Yorkshire, on the Colne, a tributary of the Calder, 14 miles S.W. of Leeds. The town is situated on the slope and summit of an eminence, and is traversed by regular and well-paved streets. The market-place is spacious, and surrounded by handsome buildings. The parish church, an elegant edifice in the perpendicular style, was rebuilt in 1837 at a cost of about L.9000. Trinity Church, erected in 1819 at a cost of L.12,000, is in the pointed Gothic style, and has an embattled tower at its W. end. St Pauls' Church, built by the parliamentary commissioners in 1831, is in the early English style, and has a tower surmounted by a light spire. The Cloth Hall is a commodious circular building two storeys in height, erected in 1765 by Sir John Ramsden, the proprietor of the town, and enlarged by his son in 1780. The lower storey is bisected by an arcade, the one half being occupied by shops, the other by rows of stalls. The average attendance of manufacturers every market-day (Tuesday) is upwards of 600. There is a proprietary college, founded in 1838, in connection with London University; also a collegiate school. The Philosophical Hall is an elegant Grecian building, belonging to the Philosophical Society, and used for lectures and public meetings. The infirmary is a large and elegant stone edifice of the Doric order, with wings and a portico supported by four fluted columns. The town is well supplied with water from reservoirs four miles to the W. of it. About half a mile from the town is a sulphureous spa, with warm, cold, vapour, and shower baths. Huddersfield is one of the principal seats of the woollen manufacture in England. Its importance is chiefly owing to its extensive canal and railway communication, and its plentiful supply of water and coal. The Ramsden Canal, 4 miles in length, communicates with the Calder; while another $19\frac{3}{4}$ miles long, passing Marsden and Stayleybridge, joins the Ashton-Under-Lyne Canal. The latter passes through a tunnel $3\frac{1}{2}$ miles long, cut through Standedge Hill. Huddersfield is connected by railway with Manchester, Leeds, Sheffield, &c. It was created a parliamentary borough by the Reform Act, and returns one member to parliament. Its rapid progress may be inferred from the fact that its population has been more than quadrupled during 50 years;—in 1801 it contained 7268 inhabitants, and in 1851, 30,880.

HUDSON, HENRY, a distinguished and ill-fated navigator of the seventeenth century. His early history is quite unknown, and he did not emerge from obscurity till the year 1607, when he was sent out by a company of rich London merchants in quest of a shorter passage to China than that by the Cape of Good Hope. In that year he penetrated as far as the 82d degree, beyond which his passage was barred by the ice. In the following year, altering his course, he sailed eastwards, and, coasting along Spitzbergen, reached the straits of Waygatz. Unable to force his way any further in that direction, he again returned home without effecting his purpose. In 1609 a company of Dutch merchants supplied him with the means of again attempting the N.E. passage. Again the ice stopped his progress, and Hudson abandoning his original plan sailed away to America, where he discovered the great river which now bears his name, and at the mouth of which New York is situated. Scarcity of provisions drove him once more to England, which he reached on the 7th November. In the following year (1610) he sailed from London on the forlorn quest of the N.W. passage. In the end of May his sailors mutinied, and the revolt was only quelled with great difficulty. In June he entered the strait and bay now called by his name, and was in high hopes that he had at last solved the mystery that had baffled so many enquirers. Stricter investigation, however, showed him that he had been caught in a cul-de-sac, and as summer was now drawing to a close, he found himself compelled to winter on these inhospitable shores with a mutinous crew, and a very scanty stock of provisions. Commander and sailors were alike out of temper at the bad success of the whole expedition, and heart-burnings and dissensions embittered the winter bivouac. On the way home in the summer of 1611, the crew again mutinied, and taking possession of the ship, they turned adrift Hudson and such of the crew as remained faithful to him, in an open boat and with a very scanty supply of provisions. What was the fate of the boat and her crew is unknown; neither was ever heard of. The details of Hudson's voyages are given at length in Purchas' *Pilgrims*, and in Harris's *Voyages*.

Hudson, *John*, a distinguished classical scholar, was born at Widehope, near Cockermouth, in Cumberland, in 1662. He was educated at Queen's College, Oxford, but after graduating as M.A. in 1684, he removed to University College, of which he became a fellow and tutor. In 1701 he was made principal keeper of the Bodleian Library, and in 1712 principal of St Mary's Hall, both of which offices he retained till his death in 1719.

Hudson obtained considerable repute both at home and abroad in consequence of his critical editions of some of the classics, of which may be mentioned his *Velleius Paterculus*, Oxford, 1693; *Thucydides*, 1696; *Dionysius Halicarnassensis*, 1704; *Geographiæ veteris Scriptores Græci minores*, with Dodwell's notes and comments, 1698, 1703, 1712; *Longinus*, 1710; *Mœris Atticista*, 1712; *Fabularum Æsopicarum Collectio*, 1718; *Josephus*, 1720. These editions are now for the most part superseded, with the exception of the last, upon the texts and notes of which he bestowed very great pains. He did not live to see it through the press, but his friend Hall charged himself with that duty, and prefixed to the edition, when complete, a biographical sketch of the deceased critic. (*Biog. Brit.*)

HUDSON, a city of North America, Columbia county, state of New York, on the left bank of the Hudson River, at the head of its ship navigation, and on the Hudson River railroad, 116 miles N. of New York city. It stands on an elevation, called Prospect Hill, which rises behind the city to the height of 200 feet. The river bank, 60 feet high, projects into the river in the form of a bold promontory, affording a delightful promenade, and having on either side a fine bay with depth of water sufficient for the largest ships. Along the margins of these bays, and at the foot of the promontory, are the wharves. The town is for the most part regularly built, with streets crossing each other at right angles. The court-house is a handsome edifice constructed of marble and limestone, and surmounted by a dome. Hudson was formerly extensively engaged in the West India trade, but of late this has mostly given place to the whale-fisheries. Its river trade is important, great quantities of produce being brought to its markets from the interior. It also carries on various manufactures, for which the streams in the vicinity afford good water-power. Pop. (1850) 6289.

HUDSON'S BAY, a large sea of North America, lying between 51 and 69 degrees of N. Lat., discovered in 1610 by Henry Hudson. (See Hudson, *Henry*; and Polar Regions.) A charter for a company, incorporated under the name of the *Hudson's Bay Company*, was obtained in the year 1670. See Fur Trade.

Hudson's Bay Territory. The first internal explorers of the vast region surrounding Hudson's Bay were traders from Canada while it was yet in the possession of France. Canadian traders had, previous to the conquest, ascended the St Laurence and Ottawa Rivers to their sources, and had formed establishments on the great Lakes. From the north-western end of Lake Superior, they threaded the intricate communication which leads by lakes, streams, and portages to Lake Winipeg, and thence penetrated some distance up the Saskatchewan River, where their most distant establishment was situated, in N. Lat. 53., W. Long. 103. These enterprises were in a great measure suspended by the struggles which ended in the conquest of Canada by Great Britain. In 1767 a party headed by a British subject again penetrated to the Saskatchewan. The Missinipi, or Churchill River, was visited by Mr Joseph Frobisher in 1775, and Lake Isle-a-la-Crosse in 1776. In the year 1781 the fur trade had reached the limits of Lake Athabasca, nearly 1000 miles beyond the most distant point attained by the French. These explorations were greatly extended by the establishment in 1783 of the North-West Company of Montreal—an association formed of the leading individuals engaged in this traffic—who, in the energetic pursuit of the fur trade, extended their establishments to the Arctic Circle and the Pacific Ocean. The charter of the Hudson's Bay Company, conferring the exclusive right of trade with the Indians, having been granted without the sanction of parliament, has generally been held invalid; and it was probably the dread, owing to this defect, of attracting public observation to their proceedings that induced the Company for many years to confine their trading stations almost entirely to the coast. In 1769, a century after the date of their charter, their farthest advance was but 400 miles inland. In that year, however, being desirous of obtaining information regarding some mines of copper described by the natives as existing near a river flowing into the sea to the northward, called the Coppermine River, they directed Mr Hearne, a gentleman in their service, to proceed overland for that river, which he had orders to survey, if possible, down to its embouchure—an enterprise in which, after two unsuccessful attempts, he succeeded, reaching the sea at the mouth of the Coppermine River on the 13th July 1771, having been thus the first to establish the existence of a great Northern Ocean washing the shores of North America. Mr Hearne's journals and charts were, however, withheld from the public for nearly twenty years after the date of his journey. On the capture of Fort Churchill by the French these documents fell into the hands of La Perouse, who commanded the French squadron, and were restored to the Company only on condition of their being published. It was doubtless owing to this circumstance that Hearne's claims to this important discovery were for many years discredited; and although the existence of a Northern Ocean was confirmed by Sir Alexander M'Kenzie, who in 1789 descended the river issuing from Great Slave Lake, which bears his name, it was not until the overland expeditions of Franklin and Richardson in 1820 and 1825 that Hearne's merits as a discoverer were fully recognised. To the expeditions last named we owe the first accurate geographical delineation of this extensive region, from the shores of Hudson's Bay as far as M'Kenzie's River. Of the country west of this stream, and extending as far as Russian America, a careful survey has been more recently executed by Professor A. K. Isbister of London, and published in the journal of the Royal Geographical Society for 1846. To this gentleman we owe also an elaborate geological map of the entire region, published in 1856 by the Geological Society of London.

The circumstances which led to the union of the North-West and Hudson's Bay Companies have been stated in the article on the Fur Trade. The new association, which retained the name of the Hudson's Bay Company, obtained in 1821 a license of exclusive trade for twenty-one years, renewed in 1842 for a similar period, over the territories W. of the Rocky Mountains—the country on the E. side being considered sufficiently protected from rival traders by the establishments of the two companies already formed there, and such vague rights as might be claimed under the charter of 1670. Grave doubts existing as to the validity of this charter, and numerous complaints having arisen from the arbitrary exercise of the powers claimed under it by the Company, an address to the Crown has been recently moved by the House of Commons for an inquiry (which is now pending) into the legality of the very wide and anomalous powers at present exercised by the Company.

The territory embraced within the present operations of the Hudson's Bay Company may be roughly estimated at nearly 4,000,000 of square miles, or somewhat greater than the entire extent of Europe. This vast area, which is covered

Hudson's Bay Territory.

by a net-work of about a hundred trading-posts scattered at distances of about three or four hundred miles apart, is divided into four large departments—1*st*, The Montreal department, which includes all the establishments situated between the River St Lawrence and the great lakes of Canada, and along the N. shore of the Gulf of St Lawrence and the coast of Labrador ; 2*d*, The Southern department, which includes the country along the N. shores of Lake Superior and the southern shores of Hudson's Bay ; 3*d*, The Northern department, which comprehends all the establishments N. of this as far as the shores of the Polar Sea ; and, 4*th*, The Columbia department, including the territory watered by the Columbia and other rivers W. of the Rocky Mountains. The departments are divided into a number of districts, each under the direction of a superior officer ; and these again are subdivided into numerous factories, forts, posts, and outposts.

In a geographical view the Hudson's Bay territories may be divided into four great natural regions—1. The Columbia or Oregon territory, a country of varied features, extending from the Rocky Mountains to the Pacific ; 2. The wooded region, occupying the country from Canada northwards along the shores of Hudson's Bay, and extending along the valley of the M'Kenzie and Peace Rivers nearly to the Arctic Ocean ; 3. The prairie region, situated between the forementioned divisions, and occupying the valley of the Saskatchewan and Red Rivers and the upper waters of the Missouri and Mississippi ; 4. The strip of sterile country along the northern shores of Hudson's Bay and the coast of the Polar Sea, familiarly known as the Barren Grounds. Of these divisions the wooded region is the most extensive and the most valuable for the purposes of the fur trade ; all the finer skins which find their way to the London market being obtained from it. It has, in consequence, been long occupied and thoroughly worked by the trading-posts and agencies of the company. The Indians inhabiting it are in general a mild, inoffensive race. Long familiarity with the whites, and the habits of trade, have produced a friendly feeling among them towards Europeans ; and their desire to supply them with the commodities of trade renders them by far the most valuable and industrious class of the population of the Hudson's Bay territories. The relation of the Company towards them is an extremely simple one : the Indians hunt and trap for the furs which the Company receive, giving in exchange such articles as are suited to the simple wants and tastes of the natives. Trade is carried on by means of a standard valuation, based on the market price of a beaver-skin, and hence denominated a *made beaver*. This is to obviate the necessity of circulating money, which is quite unknown in any part of the Indian country. A beaver-skin is considered, in the Indian trade, equivalent to two, three, or more skins of inferior value. The rates at which the skins can be obtained under the complete monopoly enjoyed by the Company render the fur trade probably one of the most lucrative species of traffic in the world.

It is difficult to form an estimate approaching to accuracy of the population of the Hudson's Bay territories. From forty to fifty different tribes, speaking distinct dialects, have been enumerated ; but the discordant estimates even of the oldest and most experienced residents in the Indian country forbid all idea of arriving at any accurate estimate of their numbers. They probably do not exceed 150,000. Their numbers are, by the most trustworthy accounts, rapidly diminishing. Through the benevolent exertions of the Church Missionary and other societies, missions and schools have been established in various parts of the country E. of the Rocky Mountains. These missions, supported entirely from the funds of benevolent bodies in England and Canada, afford the only means of education hitherto available to the inhabitants of those remote regions.

Hudson River || Huelva.

The climate and soil of the Hudson's Bay territories, except in the extreme northern districts, differ little from those of Canada, and are equally adapted for colonization. On the banks of the Red River, flowing into Lake Winipeg, a small settlement has been formed, consisting chiefly of retired servants of the Company, with their families. The colony now numbers a population of about 10,000 souls ; but from its isolated position, the bulky nature of such exports as could be furnished, and the long and dangerous navigation to Hudson's Bay, there is but little probability of its rising to commercial importance. (A. K. I.)

HUDSON RIVER, the principal river in the State of New York, North America. It rises in the Adirondack Mountains, in two streams, which unite in Warren county about 40 miles from their sources. Its course is irregular to Sandy Hill, being first S. by E. then E., after which it flows almost in a straight line nearly due S., and falls into New York Bay, in N. Lat. 40. 42., W. Long. 7. 1. 30. Its entire length is rather more than 300 miles ; its breadth below Albany varies from 300 to 900 yards. Between Haverstraw and Piermont, for 10 or 12 miles, it expands into a broad basin 4 or 5 miles wide. It has few tributaries : the Mohawk flowing into it near Troy, and the Walkill at Kingston are the principal. The scenery is in the highest degree picturesque, its elevated banks not unfrequently rising in lofty and precipitous eminences. The largest ships ascend to Hudson about 117 miles, and schooners sail as far as Troy, 166 miles.

HUE AND CRY, a custom of ancient origin for spreading an alarm. When a cry was raised by one it was caught by a second, and passed by him to a third till the whole country was roused. It was thus the ancient Britons summoned their warriors to battle. Amongst the Highlanders a half-burnt stick, dipped in the blood of a goat slain by the chieftain himself, was carried by the messenger as a threat of fire and sword to all who did not obey the summons. In 1745 this cross tarric, or fiery cross, was carried 32 miles in three hours. Cæsar speaks of a case in which an alarm was carried 160 miles in sixteen or seventeen hours.

The *hue and cry* (*putesium et clamor*) is also a legal method of procuring arrests. By 13th Edw. I., c. 3, the hundred in which the offence was committed was held responsible unless the felon was caught ; by 27th Eliz., c. 13, the hue and cry required to be made by both horsemen and footmen ; and by 8th Geo. II., c. 16, the officer neglecting or refusing to make the hue and cry is liable to a penalty of L.5. When the hue and cry is raised, all parties are obliged to join in pursuit of the criminal. A printed hue and cry is issued three times a week at Bow Street, and contains descriptions of stolen property and deserters.

HUELVA, or HUELVAS, a province of Andalucia, Spain. It has ranked as a province only since 1833, and is bounded on the N. by Badajoz, S. by the ocean, E. by Sevilla, S.E. by Cadiz, and W. by Portugal, from which it is separated to some extent by the rivers Guadiana and the Chanza. Its area is 4130 square miles, which is intersected in a S.W. direction by the western part of the Sierra Morena, locally called the Sierra Arrocha. The Odiel and the Zinto are the principal streams that drain its surface, and both fall into the Atlantic, the one at the Puerto de Polos whence Columbus set sail on his first voyage to the West. On the opposite slope of the mountains are the basins of the Guadiana and its tributaries, the Chauza, Malagon, and Albagarilla. The E. parts of the province of Huelva are composed to a large extent of vast sterile plains ; but in other portions the surface presents a pleasing variety. The highest peak is San Cristobal, at whose base are the copper mines of Rio Zinto. The soil possesses great fertility, and produces excellent pasturage, as well as oranges, lemons, citrons, grain of various kinds, and wine. The mountains are clothed with pine, oak, beech, holly, and chestnut forests, affording excellent timber. Pop. 153,462.

Huelva (ancient *Onoba*), a seaport-town of Spain, capital of the above province, on a bay formed by the mouth of the Odiel and Tinto, 50 miles W.S.W. of Seville. It carries on a considerable trade in fruit and floor-mattings, and some tunny fishing. The vestiges of a Roman aqueduct are fast disappearing. Huelva was the birthplace of José Isidoro Morales, and of Alonso Sanchez de Huelva, who discovered Española Island. Pop. 7173.

HUERTA, Vicente Garcia de la, an eminent Spanish poet of the last century, was born at Zafra, in Estremadura, in 1729. His name marks an era in Spanish literature. The eighteenth century had introduced into Spain, along with a French dynasty, a French fashion in literary matters which had completely supplanted the old national tastes, and been naturalized in the country by the genius of Luzan. Huerta was the first to rise in open rebellion against the canons of the Gallic school, and the reaction which he created and impelled was finally successful. His best work was his tragedy of *La Raquel.* The fame of this piece speedily spread far and wide, and it was soon translated into the tongues and acted in the theatres of nearly all the nations of Europe. His other tragedy of *Agamemnon Vengado* fell far short of the merit of *La Raquel.* Huerta's other works were his *Obras Poeticas*, in 2 vols. To vindicate Spanish literature more completely from the attacks of Voltaire and the French critics, Huerta made a collection of the best specimens of the national drama, in 16 vols. 8vo, which he edited with great care. His only prose work was his *Vocabulario Militar Español*, a kind of biographical dictionary of the most illustrious warriors of Spain. Huerta died at Madrid in 1797.

HUESCA, a province of Aragon, Spain, bounded N. by France, S. and S.W. by Saragossa, E. by Lérida, and W. and N.W. by Navarre. It is one of the three provinces into which Aragon was divided in 1833, and has an area of 7530 square miles, occupied by a population of 247,105. Huesca is drained by the rivers Arva, Aragon, Galego, Alcanadre, Cinca, Essera, and Noguera-Ribargoranza, and belongs entirely to the basin of the Ebro. The offshoots of the Pyrenees render the northern portion of the province mountainous; and some of the loftier summits are covered with perpetual snow. The mountainous portions are well wooded, but being generally precipitous possess little capability of culture. The more level districts are fertile and productive wherever water is sufficiently plentiful. The chief products of the soil are hemp, flax, fruits, legumes, wine, and cereals. The mountain pastures are excellent, and afford grazing for large numbers of mules, of superior quality, and cattle. Though hitherto little wrought, iron, copper, and other metals exist in great abundance throughout the mountainous districts of the province. The chief manufactures are linens, cloths, earthenware, glass, soap, and leather, and *alpargatas*, a kind of sandal peculiar to the locality.

Huesca, a very ancient town of Spain, capital of a cognominal province in Aragon. It stands on the slope of a hill in the centre of an extensive plain near the right bank of the Isuela, 35 miles from Saragossa, and 70 from Lérida. The houses are generally two storeys in height, and built with considerable uniformity; and there are several public squares; but the walls which anciently surrounded the city are now almost altogether in ruins. The principal public buildings are the cathedral, four parish churches, the royal College of Santiago founded by Charles V., and those of St Vincent, Santa Orosia, and Santa Cruz; the "Sertorio" University founded in 1354 by Pedro IV.; and the town-hall. There are also a foundling hospital, and numerous convents; two public granaries and two cavalry barracks. The industry of Huesca is chiefly confined to articles of domestic use, common coarse cloths, and leather. The annual fair held in Huesca is well frequented.

This city is so ancient that no account of its foundation was known at the birth of Christ. Strabo gives its name Ileosca (iii. 224), as the capital of the Vascitani, when it was chosen by Sertorius as the seat of the university, which he founded 77 B.C. Julius Cæsar names it Vencedora; and in the time of Augustus it was known by the name of *Urbs victrix Osca* which was stamped on its coins, and has been preserved on its arms. In 1096 A.D., Pedro I. of Aragon conquered this city after having gained in its immediate neighbourhood the battle of Alcoraz, where he slew 4000 Saracens and four Moorish kings or sheiks. This battle was fought Nov. 25, after a siege of two years. From this date it has borne for its arms the heads of the four Moorish kings, with the addition of a cross which appeared miraculously in the heavens. Pop. 9200.

HUESCAR, a town of Spain, province of Granada, in an elevated plain, between two mountain chains, 70 miles N.E. of Granada. It contains three convents, an hospital, and three churches. Its chief manufactures are cloth, linens, woollen coverlets, and damasks. Pop. 5640. At a short distance from Huescar are the ruins of a very ancient city said to have been founded by the Carthaginians, and now called Huescar la Vieja or Old Huescar.

HUET, Pierre Daniel, one of the most versatile *savans* of his own, or, indeed, of any age. Born at Caen in 1630, he was brought up in the Roman Catholic faith, to which his parents were attached. Huet's was one of those minds (so common in French literary history) which attain to a moderate proficiency in every branch of inquiry; and without being *naturalized* (so to speak) in any department, may become *acclimated* to all. Of this inquisitive temperament he gave ample evidence at the university of his native town, where his studies were prosecuted with an ardour which communicated itself to his instructors; and to the Jesuit Mambrun, the professor of philosophy, he always considered himself under peculiar obligations for a degree of attention which was all the more acceptable as the early loss of his parents had rendered it the more necessary. On attaining his majority he succeeded to an independence, which allowed him to satisfy, though not to satiate, his passion for knowledge. It was about this time that Bochart, then a fellow-townsman of Huet's, had received an invitation to Stockholm from Queen Christina, and prevailed on the young scholar to accompany him. This was an important event in the life of Huet, as he obtained access, in the great public library of the Swedish capital, to an excellent manuscript of *Origen on St Matthew*, which perhaps suggested his well-known edition of that father. On returning to his native town, after a brief stay at Stockholm, he devoted the next twenty years of his life to a diversified but systematic and profound course of study, comprising many of the exact sciences, and, above all, to the preparation of his great edition of *Origen.* He relieved the severity of his literary labours by cultivating the acquaintance of distinguished contemporary *savans*, and in this way his reputation spread so widely as to place his name on Colbert's list of literary pensions. In poetry also he found an agreeable source of relaxation, and his natural love for scenery developed itself in many a copy of verses Latin and French. The vast number of novels which he would seem to have read, may be inferred from his elaborate essay on the *Origin of Romance*, prefixed to the Contesse La Fayette's celebrated *Zaïde.* Local antiquities always occupied much of his attention; and his work entitled *Les Origines de la Ville de Caen*, written in his declining period, reached in 1706 a second edition, which, however, is a great improvement on its predecessor. But in spite of these frequent side-glances to other subjects of inquiry his attention was mainly fixed on his edition of *Origen's Exegetical Works*, which was finally published in 2 vols. folio, in 1669. The biographical and historical portions of his annotations far outweigh the value of his textual labours; and even yet no critical edition of Origen is reckoned complete which does not contain Huet's *Origeniana*. Shortly after the accomplishment of this great work, his love for the sequestered life of the cloister induced him to retire to the Jesuit's College of La Flèche, but he was not suffered long to enjoy his literary seclusion. In 1670 he was appointed sub-preceptor to the Dauphin who was then only nine years of age, and in superintending the education of that prince, he was detained at court for the next ten years. During this period he completed his most considerable work—his *Demonstratio Evangelica*, which was published in 1679. This laid the foundation of his theological fame. During the preparation of this colossal work he superintended the well-known series of the *Delphin Classics*, of which he was partly the originator. On the marriage of the Dauphin in 1679, the publication of the *Delphin Classics* ceased, and Huet was allowed to retire from court. The king presented him with an abbey at Aulnai, 12 miles to the south of Caen, and he was thus enabled to resume his former and favourite pursuits. For ten years he continued to spend his summers in this delightful retreat, and his winters at Paris or Caen; but though his literary zeal never flagged, his special subjects of study had not been sufficiently well chosen, for nothing which he has written after his fiftieth year has done much for his reputation. In 1685, however, he was appointed by the king to the see of Soissons, which he shortly afterwards exchanged for that of Avranches, in the neighbourhood of Caen. He was bishop of this see for not more than seven years, and he resigned its arduous duties for that literary ease of which he was so enamoured. The residue of his long life was spent at the Abbey of Fontenai, near Caen, where in spite of his increasing infirmities he devoted his leisure mainly to literary studies; and after an illness in 1712, so severe that his life was despaired of, he was busily engaged in compiling his *Mémoires* of himself, and those miscellaneous memoranda which were published after his death, under the name of *Huetiana*. But the care of his medical advisers and the baths of Bourbon, though they had long kept death at a distance, were unable to avert it, and in the Jesuit House in Paris, on the 26th of January 1721, he expired in his 91st year as happily as he had lived. Ever since his retirement from court, Cartesianism had been gradually advancing to importance, and its adherents, among whom were numbered the most influential men of the time, were devoting all their energies to its propagation. The main object of their attack was Aristotle, or more properly Aristotelianism; and as the Stagirite embraces or discusses in his works nearly every department of ancient literature, the entire remains of antiquity were included in their denunciations, which were promulgated in French to the neglect of Latin. All this was viewed by the Jesuits with intense dislike. Huet warmly espoused the cause of his order, and with reasoning and raillery he did his utmost to discomfit his opponents. In his *Censura philosophiæ Cartesianæ*, however, which was published in 1689, he shows an utter incompetency to meet the *Cartesians* on philosophical grounds, and cannot discriminate between the leading doctrine of their master and Pyrrhonism. His ridicule was equally ineffective; and the *Nouveaux Mémoires pour servir à l'Histoire du Cartesianisme* did as little for his cause or his reputation as his *Censura*. The most notable of his later works was his *Traité Philosophique de la Foiblesse de l'Esprit Humain*, published posthumously in 1723, which caused more excitement than all his other works put together. It contains little more than the foreshadowings of that doctrine which Berkeley and Hume carried to its utmost limit; and probably it was from the undeveloped state of his views that Huet's work was regarded with such horror at the time. He was considered a thorough sceptic for harbouring opinions which the pious bishop of Cloyne has shown to be quite compatible with a belief in the great truths of Christianity. Huet's is a name familiar in our day only to scholars as deeply read as he was in his own. Few scholars have lived with so much pleasure to themselves or have had their lot cast in easier circumstances. His long day was hardly visited by a cloud; it seems to have had all the felicity of one unbroken lucid interval; and perhaps it is for this reason that the pleasure he himself enjoyed in his literary labours has not been shared by posterity. (*Quarterly Review*, No. 194.)

HUGUENOTS, a name derisively applied to the French Protestants in the sixteenth century. It is probably a corruption of the word *eidgenossen*, or confederates, as the Genevese were called who entered into a league with the other cantons to oppose the tyranny of Charles III., Duke of Savoy. The doctrines of the Reformation in France were first publicly taught at Meaux by Lefevre and Farel in 1521. The flames of persecution were soon kindled by Francis I., and raged with increased fury after the decree against the Vaudois of Provence in 1540. The Reformed doctrines increased rapidly; and under Henry II. several whole provinces and considerable towns, numbering about a sixth of the population of France, were adherents to these doctrines. In 1559 a synod was held at Paris, consisting of members from thirteen churches. Under Francis II. they became involved in political quarrels. The conference at Poissy between Beza and Lorraine, as the representatives of the Reformers and the Papists respectively, showed the difficulty of effecting a compromise between the two parties. Under Charles IX. the opposition of the two parties assumed the aspect of a civil war. A peace was brought about by Catherine de Medicis; but when the Protestants had disbanded their forces, the old maxim was revived, that faith need not be kept with heretics. The larger Protestant towns now became scenes of butchery and bloodshed. For the massacre of St Bartholomew, at which Admiral Coligny of the noble house of Chatillon, was assassinated, see France. The edict of toleration passed in 1577 was renewed by Henry IV. in 1591, and is known as the Edict of Nantes. The oppression of the Calvinists, however, led to a religious war during the reign of Louis XIII. The *dragonnades* of Louis XIV. were a systematic attempt to compel the Calvinists, by all sorts of torture short of death, to abjure. These prepared the way for the revocation of the Edict of Nantes, which took place on the 18th October 1685. Hundreds of thousands of the most industrious population of France were reduced to ruin, and sought an asylum in surrounding countries. Still more stringent edicts were passed against the Calvinists, and their condition became worse and worse till 1760. In 1787, under Louis XVI. an act of toleration was passed in their favour. See France.

HULL, or Kingston-upon-Hull, one of the principal commercial towns of England, is situated on the north bank of the Humber, at the mouth of the River Hull, 35 miles S.E. of York. It is a municipal and parliamentary borough, and though locally in the East Riding of Yorkshire, is a county in itself. The ancient name of this town was Wyke or Wyke-upon-Hull. For more than a century previous to 1296 it was a place of considerable mercantile importance, and possessed from the Abbot of Meaux, who was lord of the manor, the privilege of holding a weekly market and a yearly fair. The natural advantages of its position for trade as well as for defence, attracted the attention of Edward I., who prevailed upon the Abbot and the other proprietors to sell him the lordship of Myton with the town of Wyke. The name of the town he changed to Kingstown-upon-Hull, and constituted it a separate and independent manor under the government of a warden and bailiffs. He afterwards, upon the petition of the inhabitants, made it a royal burgh. During his reign the duties on exports collected here amounted to nearly one-seventh of the duties collected throughout the kingdom. In the twenty-eighth year of this monarch's reign, it was appointed one of the places for the erection of furnaces for the use of the mint; and by his orders the roads leading to the town were improved, the streets paved, ferries established across the Humber, and embankments erected on the river. In the reign of the following Edward the town was regularly fortified by walls, bastions, and ditches; and these were afterwards strengthened in the reign of Richard II. When Edward III. invaded France in 1359, Hull contributed 16 ships and 470 mariners for the expedition. During the Civil War it was held for the parliament, and was twice unsuccessfully besieged by the royalists.

The town of Hull stands on a level plain, so low as to render embankments necessary to protect it from inundation. It has been greatly enlarged and improved of late years. The streets in the older part of the town are irregular and narrow, but in the more recent portions they are generally wide and regular, and lined with handsome buildings. The houses are almost all of brick. The public buildings are numerous, but are not generally remarkable for beauty. Among the principal are the custom-house, dock-office, pilot-office, excise office, stamp office, post-office, exchange, infirmary, two theatres, concert-hall, colleges, mansion-house, and gaol. The church of the Holy Trinity is a handsome cruciform edifice in the florid Gothic style, with a highly ornamented pinnacled tower rising from the point of intersection to the height of 140 feet. In the market-place is an equestrian statue of William III. A handsome Doric column, surmounted by a colossal statue, has been erected to Wilberforce, who was a native of this town. The educational institutions comprise two proprietary colleges, furnishing instruction on a plan similar to that pursued at the University and King's Colleges, London, a medical school, grammar school, Cogan's charity school for forty girls, Trinity-house school affording a nautical education for thirty-six boys, and the vicar's school for sixty boys. The charter-house is an hospital for the maintenance of fifty-seven poor persons. The Trinity-house was founded in 1369 for the support of decayed seamen and their widows. The citadel stands on the triangular piece of ground between the Humber and the Hull.

The town of Hull is admirably situated for trade. Vessels of the largest size can come up to the town; while the Hull, Ouse, and Trent, affluents of the Humber, with their tributary streams and canals, afford facilities for trade with a large extent of country. (See NAVIGATION, *Inland*.) It is also connected by railways with all parts of the kingdom. These advantages have been improved by the activity of the inhabitants, so that Hull ranks as the third port in the kingdom, the value of its exports being inferior only to those from Liverpool and London. The site of the old fortifications is occupied by docks, and thus the old town is surrounded with water from the Hull to the Humber. The old harbour was that part of the River Hull which faced the old town; but, as it was found to be inconvenient for the shipping, an act was passed in 1774 for forming a dock, now called the old dock, which has its entrance at the upper end of the old harbour. It is 1703 feet in length, 254 in breadth, and 24 in depth. Between 1805 and 1809 another dock was erected called the Humber dock. It communicates with the Humber by a lock, and is 914 feet in length, 342 in breadth, and 31 in depth. The accommodation becoming insufficient for the increasing trade, another dock was constructed between 1826 and 1829, called the Junction dock, from being formed on the land that intervened between the old and the Humber docks, and thus forming a connection between them. It is 914 feet in length, 342 in breadth, and 31 in depth. The locks are 120 feet long, 36 broad, and 25 deep. The two bridges across the locks are of cast iron, and 24 feet wide. The Railway dock, near the terminus of the Hull and Selby railway, and the Victoria, to the east of the citadel, are of recent construction. The following table exhibits the area and cost of the different docks :—

Docks.	Area. a.	r.	p.	Cost.
Old dock	10	1	11	L.73,330
Humber dock	9	3	24	233,086
Junction dock	6	0	5	165,033
Railway dock	2	3	9	115,000
Victoria dock	20	1	3	470,000
Total	49	1	12	L.1,056,449

A considerable quantity of shipping is also accommodated within the old harbour, which may be computed at 10 acres of tidal water. A timber pond of 9 acres was constructed in 1853. The quays around the docks are spacious, and are entirely surrounded with warehouses and deal yards. Hull has of late years become a principal steam-packet station. Steamers sail regularly to and from London, Leith, Aberdeen, Newcastle, Yarmouth, Hamburg, Rotterdam, Copenhagen, Antwerp, &c. Hull is the principal entrepôt of the Baltic timber trade on the E. coast of Britain. The staple imports are timber, deals, grain, and seeds, sheep's wool, tallow, hemp, flax, hides, iron bars, green fruit, bones, madder, bark, turpentine, cattle, sugar, &c. The chief articles of export are cotton stuffs and twist; woollen goods and woollen yarn; iron and hardware; linens and linen yarn; earthenware; machinery and mill work; coal, salt, and more recently raw cotton, brought from Liverpool and Manchester. The whale fishery was formerly extensively carried on. In 1819 it employed 64 vessels, but from that period it rapidly declined to 1837, and in that and the seven subsequent years employed only one vessel annually. More recently, however, a reaction has taken place, and from 1846 to 1852, inclusive, from 12 to 14 vessels have annually set out for this fishery. The number and tonnage of vessels registered at the port on 31st December 1854 were as follows :—Sailing vessels,—under 50 tons, 238, tonnage, 8822; above 50 tons, 195, tonnage, 42,861. Steam vesssels,—under 50 tons, 10, tonnage, 324; above 50 tons, 36, tonnage, 9924. The following table gives the ships and tonnage (including both sailing and steam vessels) employed in the colonial and foreign trade for 1854 and the three preceding years :—

Years.	INWARD.				OUTWARD.			
	British.		Foreign.		British.		Foreign.	
	hips.	Tonnage.	Ships.	Tonnage.	Ships.	Tonnage.	Ships.	Tonnage.
1851	1185	295,859	1433	212,709	843	235,781	1081	173,363
1852	1087	285,957	1220	175,755	758	223,260	950	139,193
1853	1107	285,641	1753	269,212	776	217,411	1285	190,591
1854	1042	256,721	1747	247,627	705	197,850	1179	177,009

The number and tonnage of vessels that entered and cleared coastwise during 1854 were :—Entered, sailing vessels, 716, tonnage, 52,414; steam vessels, 424, tonnage, 76,406: cleared, sailing vessels, 1162, tonnage, 117,279; steam vessels, 468, tonnage, 84,072. In 1852 the amount of dock duties paid was L.34,961; the amount of customs revenue, L.324,819; and the value of British manufactured goods exported, L.9,915,414. The staple articles of import being subject to low duties, or altogether free, the customs revenue is smaller than that of less important ports. The port charges of Hull have been reduced in the aggregate about L.18,000 per annum. The industrial establishments of Hull are chiefly connected with the building and equipment of ships, comprising shipbuilding yards, rope walks, and manufactories of canvas, chains, chain cables, and steam machinery. Hull is divided into 7 wards, and governed by a mayor, 14 aldermen, and 42 councillors. It returns 2 members to parliament. Pop. (1851) 84,690.

HUMBER, a large river or rather estuary of England, formed by the junction of the Ouse and Trent, and separating Yorkshire from Lincolnshire. It flows first E. for about 18 miles to Hull, and then S.E. for 22 miles to its mouth between the Spurn-head on the N., and the opposite coast of Lincoln on the S. Its average breadth is from 2 to 3 miles, but near its mouth it widens to 6 or 7. By means of its numerous tributaries it drains about 10,000 square miles, comprising some of the most fertile and populous districts of England. Vessels of considerable burden can ascend to its head, and those of the largest size to Hull.

HUMBOLDT, Karl Wilhelm von, a distinguished statesman and philologer, and the elder brother of the illustrious traveller and naturalist, was born at Potsdam, June 22, 1767. His father, who at the time of his birth, was chamberlain to the Princess Elizabeth of Prussia, was a man of wealth, and was thus able to give his sons the best education that money could procure. He trained them at home until they were of age to begin independent study; he then sent them to the university of Frankfort-on-the-Oder, which they soon exchanged for that of Göttingen. It was now that the path of the brothers began to diverge. The younger devoted himself to the study of nature; the elder found his sphere in law, the philosophy of language, and ancient literature. In the number of his friends Wilhelm von Humboldt began at this time to reckon the illustrious men who have created the literature of modern Germany. To Schiller he was especially attracted, and their correspondence from 1793 to 1803 (published at Stuttgart in 1830) shows on what terms of esteem and affection the friendship was maintained on both sides. His intimacy with Goethe gave birth to his famous critique on the *Hermann and Dorothea* of that poet, in which he gave to the world his profound discussions on the laws of epic poetry in general. Marrying in 1791, Humboldt spent the early years of his wedded life in the strictest seclusion, contributing occasional essays to the periodicals, chiefly on his contemporaries. These were reprinted in a collective form at Berlin in 1799. In the following year he was made Prussian minister at the Papal Court, and his residence at Rome gave a strong impulse to the classical bent of his tastes and studies. On his return home in 1808 he was made minister of public instruction. Unable to give effect to his views in this capacity, he retired altogether from public life for two years, and it was with some difficulty that at the end of that time he could be persuaded to go as ambassador to Vienna. For the next few years he was engaged in all the great diplomatic transactions consequent on the wars of Napoleon—at Prague, Châtillon (where, along with the chancellor, Hardenberg, he signed the capitulation of Paris), Vienna, and Frankfort. It was he too who in 1815 signed the treaty by which Saxony was compelled to abandon to Prussia a large portion of her territory. When the great European war came to an end, he was sent as ambassador-extraordinary to London; in 1818 he took part in the deliberations of the congress of Aix-la-Chapelle. On his return to Berlin he found the tone of political feeling so little consonant to his ideas and his hopes that he retired from public life altogether, and, dividing his time between his estate of Tegel and the town of Berlin, lived entirely for literature. He died April 8, 1835. His works, which are very numerous, range over a wide field, and display the rich endowments and versatility of his mind. But his best chances of fame rest on his philological works, and especially on his researches into the Basque, Sanscrit, and Malay tongues. At the time of his death he had nearly finished two important treatises; one on the languages of the Eastern Archipelago, derived from the Sanscrit, and the other on the philosophy of language. All the works essential to his fame have been recently collected by his brother Alexander, assisted by the famous Brandes.
